with kernel previously heated 5 hrs. at 105° before adding rapeseed oil, 1.20, 8.24. In tests of the lipolytic properties of kernels, pos. results were always obtained. It is suggested that the oil from fresh seeds might be used in food products, but it is more suitable for low grades of soap, for oil hardening and in conjunction with other oils in paint. C. C. DAVIS

Natural and synthetic rubber. VI. The pyrolysis of natural rubber in the presence of metallic oxides. THOMAS MIDGLEY, JR., AND ALBERT L. HENNE. *J. Am. Chem. Soc.* 53, 203–4(1931); cf. *C. A.* 24, 3129.—Pale crepe rubber pyrolyzed in the presence of ZnO or MgO gives the same decompn. products as in the absence of these oxides, but in different proportions. If the rubber mol. is represented by a long open-chain formula, the various bonds being designated by the letters, *a*, *b*, *c*, *d*, the relative ruptures during pyrolysis of straight rubber are represented by the values:

$a = 0$, $b = 0.6$, $c = 100$, $d = 0.7$; in the presence of MgO the values are $a = 0$, $b = 12.7$, $c = 100$, $d = 12.1$. This modification is attributed to an action of the oxides upon the double bonds of the rubber mol. C. J. WEST

Report on the effect on the plasticity of crepe of adding sodium bisulfite to latex. G. MARTIN AND L. E. ELLIOTT. *Trop. Agr.* (Ceylon) 75, 213–5(1930).—Samples of crepe contg. variable proportions of $NaHSO_3$ were tested for hardness and plasticity. Hardness is proportional to the $NaHSO_3$ added. The normal quantity of $NaHSO_3$ increases the mastication no. about 15% over that without it. The temp. of storage has little effect on the hardness or plasticity. Addns. of $NaHSO_3$ do not appear to increase the total mineral matter in the rubber but do make it more hygroscopic. The increased hardness cannot be due to the extra H_2O, since moist rubber does not harden as much as dry rubber on keeping. A. L. MEHRING

Composite articles of rubber and bakelite (Brit. pat. 336,292) **18.** Artificial silk [rubberized] (Fr. pat. 693,928) **23.** Organic isocolloids [for rubber] (Fr. pat. 694,339) **10.**

Rubber. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 693,975, April 7, 1930. The deterioration of rubber and like compds. is retarded by mixing with the unvulcanized rubber an org. N. compd. capable of sepg. into free radicals contg. bivalent N such as tetraphenylhydrazine or *N*-triphenylmethyldiphenylamine and afterward vulcanizing.

Creaming rubber latex. K. D. P., LTD. Brit. 337,269, Jan. 24, 1929. Concn. of latex is effected by adding to it materials such as mucilages of Carragheen moss, Iceland moss or diagum adapted to combine with water without previous hydrolysis and heating to above 60° to cause creaming.

Electrodeposition of rubber. DUNLOP RUBBER CO., LTD., D. F. TWISS, A. A. ROUND and E. W. MADGE. Brit. 336,659, July 18, 1929. Rubber or other org. material is deposited from an aq. dispersion by use of a. c. connected to rectifying electrodes, one of which is preferably Al or Ta while the other may be of Zn or C. The liquid in contact with the rectifying electrode preferably contains an electrolyte such as an alkali metal phosphate or borate which may be held in a gypsum or unglazed earthenware vessel surrounding the electrode.

Rubber compositions. I. G. FARBENIND. A.-G. Brit. 337,095, Aug. 12, 1929. A rubber compn. of good mech. strength is obtained by compounding with polymerization products such as those of butadiene or isoprene the solid substance obtained by removing the low b. p. constituents from the product of the careful low-temp. carbonization of bituminous material such as brown coal. The low b. p. constituents may be removed from the added material by distn. under reduced pressure or by extn. with acetone and the resulting material may be treated with vapors contg. O or S compds. or with S, phthalic anhydride, ZnO or other substances having a condensing action. Cf. *C. A.* 24, 4186, 5535.

Purifying gutta percha and like materials. W. S. SMITH, H. J. GARNETT and J. N. DEAN. Brit. 335,966, June 6, 1929. Crude gutta percha, balata or the like is subjected to selective extn. with a solvent acting selectively on the resins at a suitable temp. to remove the fluavil and like resins and leave behind resins of the Albane type.

Gutta percha may be treated with EtOH at 21° or with acetone at 3° in prepg. an elec. insulating product.

Rubber mixtures. RUDOLF DITMAR. Austrian 120,423, July 15, 1930. Esters of adipic acid and its derivs. are used as plasticizers for rubber. Cyclohexyl and methylcyclohexyl adipates and methylcyclohexyl methyladipate are specified.

Method of determining the plasticity and adhesion of rubber, etc., by extrusion under heat and pressure. HYDRAULIK G. M. B. H. and FRIEDRICH W. KOERVER. Ger. 516,203, Dec. 9, 1928.

Coloring rubber. I. G. FARBENIND. A.-G. and J. Y. JOHNSON. Brit. 336,446, Oct. 29, 1929. There is rolled into solid rubber such as crepe rubber one of the water-sol. components of a practically water-insol. dye, *e. g.*, 2,3-hydroxynaphthoic acid *o*-anisidide, and the dye is then pptd. within the material, *e. g.*, by use of the diazo compd. of 5-nitro-2-toluidine. Various details of procedure are described.

Coloring rubber and rubber substitutes. I. G. FARBENIND. A.-G. Brit. 335,912, May 29, 1929. Rubber substitutes made from fatty oils such as vulcanized rape-seed oil or mixed factice and linseed oil are mixed, in the form of an emulsion or suspension, with aq. pastes of org. or inorg. water-insol. coloring materials, or with dry pigments, lakes, water-insol. metal salts of org. dyes or their mixts., or with leuco compds. of vat dyes, or with reagents forming a color lake or the like *in situ* and the colored material is simultaneously or subsequently coagulated, and may be further used for coloring rubber or other plastic materials. Wetting agents such as alkyl-naphthalene-sulfonic acids or their salts may be used to facilitate the process. Cf. *C. A.* **24**, 4185, 6064.

Colored rubberized fabrics. JAMES J. CLIFFORD (to Steadfast Rubber Co.). U. S. 1,792,277, Feb. 10. For durably uniting coloring pigment to a rubber-compd.-coated fibrous fabric there is applied a non-oleaginous pigment mixt. such as Au, Ag or bronze powder together with nitrocellulose and a solvent including AmOAc and a blending ingredient such as benzene or high-test naphtha.

Coating metals or other materials with rubber. H. BECKMANN. Brit. 337,222, Nov. 14, 1929. Materials such as metals, stone, wood or cement are provided with a thin layer of rubber having exceedingly fine pores, several alternative processes for producing which are described.

Rubber product resistant to aging. WINFIELD SCOTT (to Rubber Service Laboratories Co.). U. S. 1,792,042, Feb. 10. Prior to vulcanization, there is incorporated with the rubber compn. a S deriv. of a reaction product of a ketone and a naphthylamine such as that of acetone and α-naphthylamine.

Rubber articles. DUNLOP RUBBER CO., LTD., and THE ANODE RUBBER CO., LTD. Fr. 694,676, Apr. 29, 1930. Articles are made of rubber or like material having a spongy or cellular structure, by starting with aq. emulsions or dispersions, particularly those which may be converted to a gel by heating or those to which substances have been added which will form a gel after a definite time in the cold, and transforming them into a froth or foam by a gas or by energetic stirring.

Rubber articles. DUNLOP RUBBER CO., LTD., and THE ANODE RUBBER CO., LTD. Fr. 694,768, April 30, 1930. Articles are made of rubber or the like of a spongy or cellular texture from aq. emulsions or dispersions in the state of foam contg. a gas (the emulsions or dispersions being still in the reversible state) and solidifying the foam to form a permanent mass of solid and stable material.

Hollow rubber articles. SOCIETÀ ITALIANA PIRELLI. Fr. 694,993, May 5, 1930. A core for hollow rubber articles is made of colloidal materials such as foundry earths, chalks, clay and kaolins, molded with the amt. of water strictly necessary and baked.

Inflated rubber articles such as balls. MURRELL J. DE FRANCE (to Pennsylvania Rubber Co.). U. S. 1,792,362, Feb. 10. A hollow blank is formed of incompletely vulcanized rubber, coated interiorly with successive layers of gelatin and of rubber, water and reactive gas-generating substances such as $NaNO_2$ and NH_4Cl are inclosed within the blank, and the latter is subjected to a vulcanizing temp. in a mold.

Rubber rollers. R. WHEATLEY and VICTORIA RUBBER CO., LTD. Brit. 337,250, May 30, 1930. The under layers of rubber-covered rollers are formed of sponge rubber of the isolated gas-filled pore kind.

Rubber footwear. CHARLES M. RICHARDSON and ARTHUR J. HOWE (to B. F. Goodrich Co.). U. S. 1,792,322, Feb. 10. Mech. features and an arrangement of app. are described.

Rubber boot manufacture. HOOD RUBBER CO. Brit. 336,226, July 8, 1929. A layer of relatively non-flowing material such as a mixt. of rubber with fibrous material is placed next to the lining to prevent the rubber or the like of the boot leg from filling

the spaces between the threads of the lining, to reduce the stiffness of the boot and to prevent adhesion to the last. Various details of manuf. are described.

Use of forms in making balloons, gloves, cots or other dipped rubber goods from aqueous dispersions of rubber. ISAAC W. ROBERTSON (to Thermo Process Co.). U. S. 1,792,187, Feb. 10. Various details of procedure are described.

Puncture-sealing mixture for tires. P. G. MASTERS. Brit. 335,980, July 5, 1929. A mixt. for placement in inner tire tubes is formed of castor oil 0.5 pint, talc 1.5 oz., cellulose 1.5 oz., such as wood dust, water 0.5 pint, gum acacia 1 oz. or less, with or without a small addn. of benzene, "petrol" or rubber soln.

Rubber insulating material. WM. BRYAN WIEGAND. Fr. 694,333, April 23, 1930. Insulating materials contg. rubber have added thereto C black retaining its adsorbent power in amt. up to 10% of the wt. of rubber or 3% of the total mass. An example of such a material contains rubber 984.6, ZnO 30, C black 29, monosulfide of tetramethylthiouran 3.5 and S 40 parts. Other examples are given.

Mercaptothiazole derivatives. WM. P. TER HORST (to Rubber Service Laboratories Co.). U. S. 1,792,096, Feb. 10. In producing products such as various rubber vulcanization accelerators, reaction is effected between an amine such as piperidine or diphenylguanidine and the product obtained by the reaction a salt of mercaptobenzothiazole with a Cl deriv. of CS_2. Cf. *C. A.* **24**, 2470.

Elastic material. OCTAVE PIRARD. Fr. 694,998, Aug. 2, 1929. A light elastic material is made, *e. g.*, of wood charcoal 35, bark fiber 10 and pure rubber 55%.

Transparent sheets comprising synthetic rubber. I. G. FARBENIND. A.-G. Brit. 336,075, Sept. 20, 1929. Reënforced sheets are made by applying a soft coating of a polymerization product of butadiene or its homologs to an open-meshed fabric (such as tinned iron wire mesh or a vegetable fiber material) and hardening the coating (as by the action of O or by heating). Condensation products such as those derived from oxylene or other aromatic hydrocarbons with butadiene in the presence of a condensing agent such as $AlCl_3$ also may be used.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 336,339, Aug. 2, 1929. Removal of polymerization products of diolefins from the reaction vessel is facilitated by lining the vessel with readily removable materials such as paper, cardboard, textile fabrics, leather, or films of sheet metal or cellulose derivs. or polymers of diolefins or of rubber (which latter may be vulcanized or otherwise suitably treated), or waxes, readily fusible alloys or bitumen. Various examples and details of app. and procedure are given.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 337,019, May 25, 1929. In polymerizing diolefins such as butadiene by the action of alkali or alk. earth metals or their mixts. or alloys, in the presence of org. solvents such as ether, the solns. of the polymerization products are continuously removed from the catalyst as soon as the polymerization is effected, as by a flowing stream of solvent or soln. The products may be unsuitable for the production of soft rubber, but are suitable for the manuf. of various hard materials.

Vulcanizing synthetic rubber. I. G. FARBENIND. A.-G. Brit. 335,970, July 2, 1929. Polymerization products such as those of butadiene or its homologs or analogs are vulcanized in the presence of an accelerator previously dissolved in a solvent or admixed with a liquefying agent, which gives a product of improved stretch and breaking strength. Solvents of various kinds may be used such as water, alc., hydrocarbons, chlorinated hydrocarbons, ethers, weak acids and liquid bases. Stearic acid may be used as a softening agent. Cf. *C. A.* **24**, 3400.

Rubber vulcanization accelerator. WINFIELD SCOTT (to Rubber Service Laboratories Co.). U. S. 1,792,041, Feb. 10. The reaction product of formaldehyde with crotonaldehyde dianilide is used as an accelerator. Cf. *C. A.* **25**, 618.

Rubber vulcanization. ALBERT A. SOMERVILLE (to R. T. Vanderbilt Co.). U. S. 1,791,876, Feb. 10. In effecting vulcanization with the aid of an active accelerator such as mercaptobenzothiazole a small quantity of a peroxide such as BaO_2, PbO_2, CaO_2 or SrO_2 is added to inhibit or prevent scorching or prevulcanization. Various examples are given.

Apparatus for vulcanizing rubber coatings on hollow metal articles such as press-rollers of paper-making apparatus. CHRISTIAN H. GRAY. U. S. 1,792,298, Feb. 10. Structural features.

Forming vulcanized joints in rubber articles such as air-tubes, rubber balls or other hollow products. DUNLOP RUBBER CO., LTD., and G. R. MEAD. Brit. 336,076, Sept. 21, 1929. Mech. features.

CHEMICAL ABSTRACTS

Vol. 25. MAY 10, 1931 No. 9

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Filtering disks of sintered Pyrex glass. W. F. BRUCE AND H. E. BENT. *J. Am. Chem. Soc.* **53**, 990–2(1931).—A layer of powd. glass (60-, 80- or 100-mesh), 1.5–2 mm. thick, is sintered in a Ni tube of suitable diam. About 2 min. at a bright red heat is required. The disk obtained may be sealed to a Pyrex tube. B. A. SOULE

Further applications of the centrifugal filtration tube. EVALD L. SKAU AND LOUIS F. ROWE. *Ind. Eng. Chem., Anal. Ed.* **3**, 147–8(1931); cf. *C. A.* **23**, 5355.—This device can be used to det. the approx. amt. of solid and liquid in a mixt. at any definite temp. Hence binary f.-p. diagrams may be constructed or a eutectic compn. detd. B. A. SOULE

Portable electric stirrers in the chemical industry. HANS WOLLENBERG. *Chem.-Ztg.* **54**, 804(1930).—A small, compact, well-protected elec. stirrer which can be clamped on any vessel is described. A. L. HENNE

A modified slow-combustion pipet. KENNETH A. NOBE. *Ind. Eng. Chem., Anal. Ed.* **3**, 159 (1931).—A modified Stalcie pipet for slow-combustion analysis is described, and the advantages of this method over the explosion method are pointed out. D. F. BROWN

Wash bottle for organic, poisonous or corroding fluids. WALTER FERMAZIN. *Chem.-Ztg.* **54**, 804(1930).—To the conventional wash bottle a vent tube is added. The vent is closed with a finger, while the liquid is being forced out of the bottle. To interrupt the liquid stream the finger is lifted before blowing is stopped. This prevents disagreeable fumes from backing into the operator's mouth. A. L. HENNE

Comparative efficiencies of gas-washing bottles. F. H. RHODES AND D. R. RAKESTRAW. *Ind. Eng. Chem., Anal. Ed.* **3**, 143–4(1931).—Each bottle was filled to the normal working height with NaOH (32.7 g./l.). Then air contg. 13.4% CO_2 was passed through at increasing rates of flow until that rate was found at which some CO_2 escaped absorption. The order of decreasing efficiency is: Friedrichs spiral, Schott & Gen. No. 101, No. 83c, No. 83, Muencke, Habermann. The order is approx. the same when 5.1% CO_2 is used. B. A. SOULE

Direct-reading volume-meter. M. T. CARLISLE AND RHEBA USHER. *J. Chem. Education* **7**, 1562(1930).—This vol.-meter for irregular solids consists of a cylinder 4.8 cm. in diam. and 12 cm. long, the bottom of which is drawn out into a tube 10 cm long contg. a bulb of 10 cc. capacity. A glass stopper with a finely graduated outlet tube, 30 cm. long and 5 mm. in diam., is inserted in the top of the cylinder. A leveling bulb of Hg is attached to the bottom tube. The cylinder and bottom tube are filled with water, after which the leveling bulb is brought up to a mark on the botrom tube. The level of the column of water forced up into the upper outlet is then read and the leveling bulb lowered again. After the test specimen is dropped into the cylinder, the operation is repeated and the difference in water levels noted. ANN NICHOLSON HIRD

Potentiometer for the determination of p_H. N. N. KAVTZEVICH. *Ann. Weissruth. Staatl. Akad. Landw. Gory-Gorki* **9**, 245–60(1929).—Potentiometric measurement of the e. m. f. is discussed, and a simplified potentiometer which gives readings with an accuracy of 0.01 p_H is described. The novel feature of the potentiometer is the introduction of a telephone in place of the galvanometer. J. S. JOFFE

Colloid mills. AUGUST CHWALA. *Kolloid-Z.* **54**, 243–51(1931); cf. *C. A.* **25**, 1122.—A review of German patents. ARTHUR FLEISCHER

An automatic constant-level device for liquid air. R. B. SCOTT AND F. G. BRICKWEDDE *Rev. Sci. Instruments* **2**, 171–2(1931). E. H.

Apparatus for the continuous extraction of large quantities of material at high temperatures. FRITZ WREDE. *Biochem. Z.* **231**, 173–4(1931).—An app. capable of extg. 5 kg. or more of material has an outer vessel that contains a heating liquid (liquids of various b. ps. can be used for extn. at diff. temps.) and an inner container for the ma-

terial and the solvent. The solvent is boiled in a flask outside the container, so connected that the solvent circulates through the material and then returns to the flask.
S. MORGULIS

Extraction apparatus. R. C. BAKER. *J. Soc. Chem. Ind.* **50**, 54T(1931).—A drawing showing a modified Soxhlet extractor is given, and the advantages possessed by the app. over the usual type are presented. N. A. LANGE

Note on centrifugal dust extractors. M. SEILLAN. *Chaleur et ind.* **10**, 289–93 (1929); cf. *C. A.* **24**, 992.—S. discusses the trajectory of an element of gas emerging from the rotor of a centrifugal pump and draws the parallelogram of velocities at the exit of a ventilator. This is followed by a discussion of cyclone extractors.
S. L. B. ETHERTON

An apparatus for determination of true vapor pressure. E. J. SQUIRE. *Petroleum World* **28**, No. 1, 66–79, 101–9(1931).—An app. for detg. true vapor pressure should be designed so that the sample may be introduced as it exists at the point of sampling, so that vapor pressures may be detd. at different temps., and so as to be speedy enough in operation for routine testing. The app. here described can be said to meet these conditions and is suitable for liquids that do not attack Fe, Hg or glass, are not too viscous to be properly agitated, do not have an abs. vapor pressure over 2000 mm. of Hg, and do not contain emulsion. R. W. KELLY

Apparatus for purifying gases. Z. VERESS. *Magyar Chem. Folyoirat* **35**, 155–7 (1929).—The current of gas drives the solvent into an absorption tower, whence it returns dropwise into the original container. B. C. A.

The technic of gas analysis. A. J. ANTHONY. *Z. Biol.* **90**, 633–6(1930).—An *app.* equipped with shaking attachment is described. The specific difficulties for nitrous oxide analysis are discussed. FRANCES KRASNOW

Automatic analyzers of gas mixtures based upon thermal conductivity of gases and their industrial use. DE FROBERVILLE. *Chaleur et ind.* **11**, 469–71(1930).—A discussion of an article by Jarrier (cf. *C. A.* **25**, 1413), in which F. meets the weaknesses of app. described by J. PAUL JARRIER. *Ibid* 471–2.—J. replies and gives more detail.
S. L. B. ETHERTON

A new titration colorimeter. K. MAYER. *Biochem. Z.* **231**, 314–6(1931).
S. MORGULIS

Helical pumps and their use in industry. ERNST BLAU. *Chem.-Ztg.* **54**, 801–2 (1930).—Descriptive. A. L. HENNE

Improvements in the construction and use of the Berthelot-Mahler calorimeter. RICCARDO DE BENEDETTI. *Rivista tec. ferrovie ital.* **38**, 56–60(1930).—Several details of the mech. parts of the app. are modified, and methods of calibrating and operating are suggested for serial work and for the detns. with liquid combustibles. G. A. B.

Generator for the production of carbon dioxide of high purity. EDGAR J. POTH. *Ind. Eng. Chem., Anal. Ed.* **3**, 202–3(1931).—The construction of a generator for CO_2 or other gases is described, for which the following advantages are claimed: (1) It is compact and is constructed entirely of glass without ground-glass joints. (2) It can be warmed and pumped free of occluded gases. (3) It has a novel automatic feeding arrangement. (4) Reagents are completely used, and none of the gas produced is wasted. CHANNING WILSON

Flow divider for fractionation under diminished pressure. A. M. SCHWARTZ AND M. T. BUSH. *Ind. Eng. Chem., Anal. Ed.* **3**, 138–9(1931).—In vacuum distn. total condensation and return of part of the condensate as reflux permit complete and easy control of the reflux ratio. A stillhead with a Hg check valve has been found suitable for this purpose. Constructional details are given. B. A. SOULE

Glass temperature and float regulators. D. F. OTHMER. *Ind. Eng. Chem., Anal. Ed.* **3**, 139–43(1931).—Constructional and operating details are given for a controller of pressure or temp. when a flowing liquid causes the change of conditions. The sensitive element is a vapor-pressure bulb that operates a "flow diverter." A temp., never over 0.2° high, may be maintained for weeks. The device is recommended for lab. or semi-works operations. Several float valves are also described. B. A. S.

Glass electrode and vacuum-tube potentiometer. DONALD H. CAMERON. *J. Am. Leather Chem. Assoc.* **26**, 7–23(1931).—Advantages and limitations of the electrode are discussed. In tannery analyses, the chief advantage is freedom from poisoning and disturbance by oxidation-reduction reactions; the chief disadvantage, aside from the rather laborious standardizations required, is the failure to function at p_H values higher than 9. Different forms of electrode are described: MacInnes' form, using the Ag-AgCl electrode, is preferred. A vacuum-tube potentiometer circuit, on the Wheatstone bridge principle, is described in detail. H. B. MERRILL

A vacuum-tube method of temperature control. FRANCIS O. SCHMITT AND OTTO H. A. SCHMITT. *Science* **73**, 289–90(1931).—The app. is essentially a type FG-27 thyratron regulator tube with a toluene-Hg regulator inserted in the grid circuit. A large un-insulated metal water bath has been held for days to within 0.005°; well insulated baths may be held within 0.001°. J. H. MOORE

Something new in vacuum drying chambers. HOLLAND-MERTEN. *Chem.-Ztg.* **55**, 153–4(1931).—A rectangular chamber, built by Vacuumtrockner, Erfurt, is described. It is made up of independent heating elements, any no. of which may be used, the sides of the elements forming the walls of the chamber. Internal dead space is eliminated; internal condensation and steam leakage are minimized; and less wt. and floor space are required for a given capacity. J. H. MOORE

The determination of the heat of wetting. WALTER REIMER. *Wiss. Arch. Landw.*, Abt. A., *Pflanze.* **4**, 383–91(1930).—A new *calorimeter* for detg. the heat of wetting is described. The heat tone is measured by the expansion of toluene, which surrounds the inner wall of the calorimeter and connects with a graduated capillary tube. A sensitivity of 0.25 cal. is possible. Details of the construction and use of the calorimeter are given. W. GORDON ROSE

Chemical engineering memoranda. XIII. Further notes on heaters, including air heating by steam. CHARLES H. BUTCHER. *Ind. Chemist* **7**, 95–6(1931); cf. *C. A.* **25**, 364. E. H.

A very sensitive, self-registering heat-flow meter. GEORG HOFBAUER. *Arch. Wärmewirt.* **10**, 398–402(1929).—The instrument, which is intended primarily for measuring heat flows through the walls of buildings, consists of 5 multiple couples, each contg. 100 Fe-constantan elements, with junctions on opposite sides of a rubber sheet 0.3 cm. thick, which is protected by thin outer rubber sheets and surrounded by a protecting ring. Good accuracy can be attained with flows as low as 1.5 cal. per sq. cm. per hr. ERNEST W. THIELE

The energy problem of electric heating. F. MERKEL. *Arch. Wärmewirt.* **10**, 407–8(1929).—A general discussion of *heat pumps* with special reference to their use in *distn.* ERNEST W. THIELE

Packed heat from a new type of electric steam generator. HOWARD BIDWELL AND LINUS H. JONES. *Ind. Eng. Chem.* **23**, 298–300(1931).—The problem of obtaining large quantities of high pressure steam for short periods for sterilization work has been solved by the construction of an elec. steam generator of original design. The boiler of the generator is offset at an angle, almost the entire vol. of water in the generator and reservoir being made available for steam. Immersion heating elements are used, the size and energy consumption depending on the pressure and quantity of steam required. The design incorporates the safety features of small diams. Sterilizing pressure may be obtained within 30 sec. from the time of closing the autoclave. A. S. S.

A practical hot stage for the microscope. EDWARD H. WALLACE AND MARY L. WILLARD. *J. Chem. Education* **8**, 706–11(1931). E. H.

Modern electrically heated aluminum-fusing furnaces. KIRCHRATH. *Metallbörse* **20**, 2731–2, 2779–80(1930).—Furnaces, especially those built by Gautschi and Brandt, with Ni-Cr heating elements, are described. The elements are either bands or spirals placed in recesses in the roof so that heat is radiated down on the charge. J. H MOORE

Determination of the local strength of fabrics, felts, paper, rubber, film, wood, leather, metal, etc. II. FRIEDRICH SCHUBERT. *Chem.-Ztg.* **55**, 134–5(1931); cf. *C. A.* **25**, 1708.—The *app.* referred to in *C. A.* **23**, 1187, 4103, has demonstrated its value. It is described, its use and the results are discussed and a sample calcn. is given. J. H. MOORE

Early steps in the development of the Columbia soil rod. BUELL B. LEGG. *Gas Age-Record* **67**, 111–8(1931).—Work is being done on the development of a soil rod which will enable the determination of the galvanic action of the soil, the specific resistance, the tendency to polarization and the potential difference between adjacent soils. Preliminary work indicates a close relationship between results obtained with such a rod and corrosion of test samples. The rods at present have a copper electrode and a steel electrode suitably insulated. The bottom, steel electrode is tapered to provide a driving tip. LESLIE B. BRAGG

Modification of Ostwald's electric thermoregulator. E. BUTTERWORTH AND D. A. DERRETT-SMITH. *J. Sci. Instruments* **7**, 233(1930).—Change in calibration due to allowing the instrument to cool is avoided by omitting the 2 side tubes of the standard form, sufficiently fine adjustment being obtainable by means of the screw in the terminal

head. It is advisable to distil the toluene over Hg to insure complete removal of S. B. C. A.

A laboratory thermostat for continuous operation. P. W. SCHENK. *Ber.* **64B**, 368–70(1931).—A thermostat is described which will operate without special attention for a long period of time with an accuracy of 0.02°. A Dewar tube is surrounded by a wooden box which contains the stirring motor, battery, relay, condenser and Hg switch. A particular feature of the thermostat assembly is the inclosed Hg switch operated by a relay and making and breaking the current to two cylindrical heating bulbs in the thermostat. The relay is actuated by a Hg-in-glass thermoregulator. A condenser of 1–2 mf. is used across the regulator. For temps. below room temp. a const. stream of water is passed through a Cu U-tube in the thermostat, and the same heating system is used to maintain the lower temp. ALLEN S. SMITH

Simple universal thermostat for laboratory fermentations, refractometry and pycnometry. H. FINK. *Wochschr. Brau.* **47**, 461–4(1930).—This app. consists of a eudiometer with capillaries and containers for fermentation, a thermostat with heating elements, thermoregulator and stirrer, and an electrically driven shaking device and fillings to accommodate 20 pycnometers and 12 capsules mounted for reading by an immersion refractometer. Six or 12 fermentation flasks can be used at once, These are provided with gas-measuring fittings. The bath remains const. within 0.2° and is used within the range 15° to 40°. S. JÓZSA

Oven-temperature control and design of a bi-metal thermostat. W. E. BENTON. *Gas World* **94**, 35–7(1931).—A math. treatment of the fundamental principles of bi-metal thermostat design. F. H. BERGEIM

A cooling unit for low-temperature thermostats. T. J. B. STIER. *Science* **73**, 288–9(1931).—A Cu funnel is fed with cracked ice from an insulated hopper, with means for drawing off water as the ice melts. The funnel is immersed in the thermostat to the proper level, found by trial, and will hold the app. const. to ±0.01° at room temps. It costs about $1.00. Details are given. J. H. MOORE

Ag and its application to chemical plant (MCDONALD) **9**. Colorimeters, spectrophotometers and nephelometers (DIGAUD) **7**.

Colorimeter. JOHN C. BAKER and CHARLES F. WALLACE (to Wallace & Tiernan Products, Inc.). U. S. 1,794,134, Feb. 24.

Immersion pyrometer for fused metals. RUDOLF HASE. Ger. 514,682, May 11, 1929. Details of construction are described.

Optical absorption-pyrometer. KAISER-WILHELM INSTITUT FÜR EISENFORSCHUNG E. V. (Gerhard Naeser, inventor). Ger. 517,023, July 9, 1929.

Thermometer. MAX E. MOELLER (to Moeller Instrument Co.). U. S. 1,793,950, Feb. 24.

Thermometer connected with an indicator at a distance. HERMAN SCHLAICH. U. S. 1,794,324, Feb. 24. Structural features.

Distance signalling thermometer suitable for use in stacks. D. G. ZEITLIN. Brit. 338,267, Sept. 14, 1929. Structural features.

Thermometer or like device containing a gallium alloy. SYLVESTER BOYER (to General Elec. Co.). U. S. 1,793,303, Feb. 17. Ga or alloy which may contain Ga, Sn and In is placed in a tube of material such as fused SiO_2 to which the alloy does not adhere.

Viscometer. HARRY W. KLINGER (to Hercules Powder Co.). U. S. 1,793,807, Feb. 24. X-rays are utilized for observing the passage of a ball or the like through opaque liquids. Cf. *C. A.* **25**, 3.

Air filter. LOUIS KLAFF (to American Air Filter Co.). U. S. 1,794,115, Feb. 24.

Air filter. ALBERT BENTELI-HÜSSY. Swiss 142,423, Oct. 4, 1929. A labyrinthine passage for the air causes deposition of foreign bodies.

Air filter for liquid-storage vessels. KAREL PRILLINGER and FRANTISEK PRILLINGER. Swiss 142,109, Sept. 11, 1929.

Fabric air filter. C. G. VOKES. Brit. 337,966, Nov. 1, 1929. Structural features.

Oil filter. CHARLES W. MCKINLEY (to A C Spark Plug Co.). U. S. 1,792,854, Feb. 17.

Unactivated "prefiltering medium" suitable for treating oils, sugar solutions, etc. JOHN J. NAUGLE. U. S. 1,794,862, March 3. A material of low decolorizing and deodorizing value, but which has a highly porous structure permitting a high rate of filtration, comprises carbonized lignin residues substantially free from all alk. residues.

Filter cloths. VICTOR ROEDER. Ger. 517,260, Jan. 18, 1929. Peripheral reenforcing means for perforations in the cloth is described.

Apparatus for filtering liquids under pressure. J. HOFFMANN and T. KRIEBERNIGG. Brit. 337,848, Aug. 14, 1929. Structural features.

Rotary, impeller agitating device and filter for treating liquids such as sugar solutions or oils. JOHN J. NAUGLE. U. S. 1,794,916, March 3. Structural features.

Magnetic separator. MITSUO KOIZUMI. Ger. 517,259, Apr. 8, 1925. Corresponds to Brit. 254,030.

Means for separating pneumatically conveyed materials from the conveying medium. WILHELM KNOLLE. Ger. 517,050, Jan. 17, 1928.

Separator for oil and water, etc. IGNAZ MÜLLER. Ger. 517,425, Apr. 20, 1929. See Austrian 115,650 (*C. A.* **24**, 2286) and 117,500 (*C. A.* **24**, 3403).

Apparatus for separating oil from compressed air. MARTIN J. BINKLEY (to Caloroil Burner Corp.). U. S. 1,793,460, Feb. 24. Structural features.

Settling apparatus suitable for the separation of solids from liquids and gases. WALTON C. GRAHAM, HORACE S. RUMSEY and ASHUR U. WETHERBEE (to Gilchrist & Co.). U. S. 1,794,374, March 3. Structural features.

Spray-system washer for separating dust from gases. DAVID S. JACOBUS (to Babcock & Wilcox Co.). U. S. 1,793,620, Feb. 24. Structural features.

Röntgen-ray tubes. W. D. COOLIDGE (to British Thomson-Houston Co., Ltd.). Brit. 338,430, Jan. 16, 1929. Structural details of tubes which may have a Mo plate of sufficient thickness to assume a uniform temp. and a surrounding focusing member of Ni or Mo.

Quartz rod (with a cone-shaped depression in its end) for use with ultra-violet lamps. CLEON W. SYMONDS. U. S. 1,794,557, March 3.

Thermionic cathode. SANDOR JUST (to General Elec. Co.). U. S. 1,794,298, Feb. 24. A cathode is formed of a metal such as Mo having a m. p. above 1000° and an electron-emissive material comprising a mixt. of oxides including an alk. earth oxide and a rare earth metal oxide, in which the latter is present to only about 0.1% the quantity of the former.

Electron-discharge apparatus. DUDLEY A. MULLANEY (to General Elec. Co.). U. S. 1,794,315, Feb. 24. A control electrode for a space current device has its surface mechanically roughened to decrease emission of secondary electrons from it.

Electron-discharge devices. ÉTABLISSEMENTS INDUSTRIELS DE E. C. GRAMMONT ET DE A. GRAMMONT. Brit 337,971, Dec. 10, 1928. Electron-emitting filaments (which may be formed of pure or oxidized W or of W coated with oxidized metal such as Fe, Ni or Cu and may if desired be wound with fine taping to retain the coating) are coated with alk. earth metal oxide by depositing on the filament a single or double cyanide of the alk. earth metal and decompg. the cyanide to form the oxide after the filament is mounted in the electron, discharge device. Various details of procedure are described.

Electron-discharge devices. H. C. RENTSCHLER (to Westinghouse Lamp Co.). Brit. 337,704, Feb. 16, 1929. Oxidation of the surface of the anode may be effected by cooling in air after baking in H, and selective reduction of the oxides of Ni and Fe may then be effected by H at 800–1000°. A small proportion of H_2O vapor in the H prevents the formation of nitride or carbide of Cr due to the presence of any N or satd. hydrocarbons in the gas used. For further details see U. S. 1,760,525 (*C. A.* **24**, 3405).

Discharge device for compressed gases such as carbon dioxide. RENEE M. LEMOINE. U. S. 1,794,185, Feb. 24. Plugs of porous material such as tow impregnated with a liquid of low f. p. such as alc. are placed in expansion devices at the points which are most exposed to freezing. U. S. 1,794,186 relates to an app. for atomizing paints, insecticides, etc., with CO_2.

Gas-analysis apparatus. J. G. DALOZ. Brit. 338,410, June 20, 1929. Various structural details are described of an app. suitable for detn. of fire damp. The app. may be attached to a *miner's lamp*.

Automatic gas-analysis apparatus. C. A. HARTUNG. Brit. 337,862, Aug. 21, 1929. Various details are described of app. in which the gas to be tested, such as flue gas, is treated with another gas such as H and reaction effected as for the purpose of detg. residual O in flue gases.

Apparatus for determining and registering the density of gases and liquids. SIEMENS & HALSKE A.-G. (Josef Krönert and Heinz Grüss, inventors). Ger. 517,364, Mar. 11, 1928. The detn. depends on the velocity at which the gas or liquid flows through a narrow orifice.

Apparatus for carrying out catalytic reactions between gases under high tempera-

ture and pressure. MARIA CASALE-SACCHI. Swiss 142,144, Apr. 5, 1929. Details are given.

Apparatus for the catalysis of gas. SOC. ANON. D'OUGRÉE-MARIHAYE. Swiss 141,303, Mar. 4, 1929. The app. is used for such catalytic reactions as the *oxidation of* NH_3 into oxides of N.

Apparatus for maintaining a desired relation between the pressures of gas and air, etc. A. C. IONIDES. Brit. 337,955, Oct. 28, 1929. Various structural details are described.

Device for regulating the quantity and composition of gas mixtures such as those used for anesthesia. ANTON GRAMBERG (to I. G. Farbenind. A.-G.). U. S. 1,793,608, Feb. 24. A device is described for operating needle valves controlling the supply of the gases.

Apparatus for treating gases with liquid sprays for washing, saturating, cooling or other purposes. J. A. REAVELL. Brit. 337,507, Aug. 22, 1929. Structural features.

Gas washer, with rotary perforated washing drum. ZSCHOCKE-WERKE KAISERSLAUTERN A.-G. (Ernst Heilmann, inventor). Ger. 517,352, Oct. 26, 1929.

Device for mixing liquids with added substances, for chemical reactions. EUGEN STEUER. Ger. 514,937, June 9, 1929.

Centrifugal atomizer for liquids. AKTIESELSKABET NIRO. Ger. 514,714, July 18, 1926. The app. comprises a rapidly rotating plate and is used for atomizing liquids preparatory to their reaction with gases.

Centrifugal drum apparatus for clarifying liquids. H. LIST. Brit. 337,628, Nov. 22, 1929. Structural features.

Apparatus for clarifying aqueous liquids, etc., by gravity separation. FRITZ MIEDER. U. S. 1,792,919, Feb. 17. Structural features.

Apparatus for extractions with liquid solvents. LE ROY C. TRESCOTT (to Contact Filtration Co.). U. S. 1,794,874, March 3. Various details of construction are described of an app. for extn. on the Soxhlet principle, such as extn. of clay used in filtering oil. An agitating device is mounted in the extn. chamber.

Valve for regulating the flow of liquids or liquefiable solids such as sulfur, wax, fat, pitch, etc. ARTHUR T. PRENTICE (to Imperial Chemical Industries, Ltd.). U. S. 1,793,747, Feb. 24. Structural features.

Noncorrodible container for liquids. WILHELM BESCHIETZNICK. Ger. 514,588, Nov. 27, 1929. The container is built up of sections coated with Pb, Cu, Al or other noncorrodible plates.

Evaporator with steam-heated tubes suitable for concentrating liquids. FRANZ HOFMEISTER and HANS MELHARDT (to Chemische Fabriken J. Bellak). U. S. 1,793,174, Feb. 17. Structural features.

Evaporating apparatus. KARL FRIED. Ger. 517,176, Jan. 8, 1928. The app. combines evapn. in thin layers with multiple-effect vacuum evapn.

Hollow-plate heating apparatus for evaporating liquids, etc. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 338,097, April 29, 1929. Structural features.

Multistage steam drier. SCHMIDT'SCHE HEISSDAMPF-G. M. B. H. (Otto H. Hartmann, inventor). Ger. 514, 883, Dec. 17, 1920.

Centrifugal drier with a filter drum. I. G. FARBENIND. A.-G. and FRITZ SANDER. Ger. 514,568, July 23, 1927. Addn. to 401,162.

Apparatus for drying steam. CHRISTIAN HÜLSMEYER. Ger. 517,402, May 10, 1928.

Apparatus for drying sheet materials. COE MFG. CO. Brit. 337,432, May 29, 1929. Structural features.

Apparatus for drying materials by circulating air which is alternately heated and cooled. JOHAN G. OLSSON and FRANS I. E. STENFORS. U. S. 1,795,094, March 3. Structural features.

Apparatus and procedure for spray desiccation of materials such as blood, milk or soap. FRED F. PEASE (to F. F. Pease, Inc.). U. S. 1,794,978, March 3. Structural and mech. details.

Sealing ring for rotating cylinder apparatus such as kilns and driers. BUKNETT E. GREEN (to Huron Industries, Inc.). U. S. 1,794,454, March 3.

Rotary cooling drum (for cooling material discharged from rotary furnaces or kilns). H. STEHMANN (to F. Krupp Grusonwerk A.-G.). Brit. 338,069, Jan. 18, 1929.

Atmospheric water spray cooling tower. CARL F. BRAUN (to C. F. Braun & Co.). U. S. 1,794,394, March 3.

Vapor-liquid contact column suitable for distillation, dephlegmation, absorption,

etc. CLAUDE B. SCHNEIBLE (to trustees of Joseph Schneible Trust). U. S. 1,794,986, March 3.

Column-and-superposed-tray apparatus for removing carbon by washing from bubble towers used for oil distillation. GUY B. BOGART (to Texas Co.). U. S. 1,792,887, Feb. 17. Structural features.

Surface condenser suitable for use with steam. PAUL A. BANCEL (to Ingersoll-Rand Co.). U. S. 1,794,135, Feb. 24. Structural features.

Apparatus for aerating water with carbon dioxide. H. ZWICKY. Swiss 141,040, Sept. 24, 1929.

Apparatus for proportionate mixing of chemicals with water or other fluids supplied through pipes. JAMES W. PARKER, SABIN CROCKER and JAMES H. WALKER. U. S. 1,792,757, Feb. 17. Structural features.

Condensing apparatus suitable for use with steam engines or turbines. RAYMOND P. MOORE (to Ingersoll-Rand Co.). U. S. 1,793,119, Feb. 17. Structural features.

Tiltable pan for receiving ammonium salts from saturators. FIRMA CARL STILL. Ger. 517,476, July 7, 1928.

Lip-tilting crucible furnace. J. H. LUDLOW and ASSOCIATED ELECTRICAL INDUSTRIES, LTD. Brit. 338,013, Nov. 25, 1929.

Muffle furnace. ZAHN & CO. G. M. B. H. Ger. 514,502, May 31, 1927. A muffle furnace with a heat-resisting hearth for the production of sulfate from NaCl and H_2SO_4 or bisulfate, is described.

Horizontal or muffle furnace suitable for treating sand to remove its iron content. V. A. COLLINS. Brit. 337,845, Aug. 13, 1929. Structural features.

Annealing furnace. VEREINIGTE DRAHTWERKE A.-G. (TRÉFILERIES RÉUNIES S. A.). Swiss 138,657, May 10, 1929. Details of preheating and cooling are given.

Chamber furnace with regenerative chamber for preheating air and gas. C. OTTO & CO. G. M. B. H. Ger. 507,912, Feb. 28, 1929.

Twin chamber furnace. C. OTTO & CO. G. M. B. H. Ger. 517,175, Mar. 5, 1927. Addn. to 511,515 (*C. A.* **25**, 1127).

Regulator for inclined-grate furnace. FIRMA M. STREICHER. Ger. 514,665, July 6, 1928.

Traveling-grate furnace with compressed air admittance below the grate. L. & C. STEINMÜLLER. Ger. 514,843, July 19, 1929.

Oil-fired furnace. ERNST FELDHOFF (Erich W. Becker, inventor). Ger. 514,521, Dec. 7, 1928.

Gas-fired boiler with plate-like members. STREBELWERK G. M. B. H. Ger. 514,873, Apr. 19, 1929.

Gas-fired annular chamber kilns. LUDWIG RIEDHAMMER. Ger. 517,334, Mar. 1, 1929. A method is described of attaining uniform temps. in the upper and lower parts of the combustion chambers.

Gas burner. CHARLES J. SCHIFFERLE (to Harry R. Struthers). U. S. 1,794,868-9, March 3.

Gas burner. J. W. BAKHUIZEN. Brit. 338,345, Nov. 5, 1928.

Safety pilot-jet system for gas burners. A. C. BECKER. Brit. 338,122, April 13, 1929. Two pilot jets and a main burner and assocd. devices are so arranged that in the event of one of the pilot jets being extinguished it is reignited from the other. Brit. 338,124 and Brit. 338,128 also relate to similar devices.

Furnace wall with parallel tubes for cooling. OSCAR NYGAARD. U. S. 1,793,004, Feb. 17.

Means for heating or intensively cooling hollow rolls or drums for working rubber, etc. PAUL TROESTER, MASCHINENFABRIK. Ger. 517,361, July 9, 1930.

Heat-exchange apparatus suitable for use as a condenser. GEORGE T. JACOCKS (to Alco Products, Inc.). U. S. 1,794,336, Feb. 24. Structural features.

Heat-exchange apparatus suitable for heating air for combustion by hot gases. JEAN B. E. E. ARNOULT (to Établissements Ernest Arnoult). U. S. 1,794,573, March 3. Structural features

Apparatus for electric heating of liquids in receptacles by immersed electric resistance devices. W. WINSHIP. Brit. 337,762, May 3, 1929. Structural features.

Heating and cooking vessels. "SFINX" SPOJENÉ SMALTOVNY A TOVÁRNY NA KOVOVÉ ZBOŽÍ AKC. SPOL. Brit. 337,313, Dec. 24, 1929. An inner vessel such as one of rustless steel is fitted within an outer sheath or jacket of metal of higher heat cond. such as Al or Cu. Various structural details are described.

Apparatus suitable for heating chemicals in large kettles, etc. SIDNEY E. MEYERS (to National Aniline & Chemical Co.). U. S. 1,792,918, Feb. 17. Various details are

described of a heating system by which a large kettle or the like is heated by hot fluids such as combustion gases supplied from an adjacent furnace.

Apparatus for dispelling fog and mist with heated air. EDWARD C. READER. U. S. 1,793,719, Feb. 24. App. is described suitable for use at aircraft landings, etc., which comprises an externally heated conduit through which air is forced which is then discharged as a forceful, voluminous blast into the fog or mist.

Apparatus suitable for mixing measured portions of opaque substances with röntgenologists' solutions. GEORGE W. HOPKINS. U. S. 1,794,769, March 3. Structural features.

Apparatus for "neutralizing" poisonous gases such as those from gasoline engines. DANIEL A. MACKINNON. U. S. 1,793,813, Feb. 24. Structural details are described of an app. suitable for treatment of the gases with catalytic material such as oxidized Cu.

Apparatus for electrical conductivity tests on water in bore holes (to determine character of surrounding rocks). SOC. DE PROSPECTION ELECTRIQUE (PROCEDES SCHLUMBERGER). Brit. 337,489, Oct. 26, 1928. Structural and elec. features.

Mercury-vapor boiler. WALTER E. TRENT (to Trent Process Corp.). U. S. 1,792,784, Feb. 17. The interior of the boiler is surfaced with a material such as Ag which is wetted by Hg.

Apparatus for testing wearing of gears, etc., in various atmospheres. M. FINK. Brit. 337,511, Aug. 24, 1929. Wear is stated to be greater in gases contg. O than in inert gas such as CO_2.

Apparatus (with superposed mixing chambers and agitating devices) for dissolving xanthates. RICHARD THURM and EUGENE SCHMIERER (to Baker Perkins Co.). U. S. 1,794,214, Feb. 24. Structural features.

Apparatus for making amalgams, particularly for dental use. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Ger. 517,202, Mar. 27, 1928.

Apparatus for estimating the humidity of foundry sand, etc., by determining the electrical resistance. FRITZ TÖDT. Ger. 517,212, Dec. 23, 1928.

Valve for operation under high temperatures and pressures. W. PFEIFFER and K. REISS. Brit. 337,838, April 18, 1929.

Acetylene generators. PAUL WIDERKEHR. Swiss 142,961, July 22, 1929. App. for producing C_2H_2 from water and CaC_2, having a hollow vessel for regulating the C_2H_2 pressure, is described.

Transport drum for carbide, etc. GUSTAV HILGER. Ger. 517,281, Nov. 10, 1929. Addn. to 489,305 (*C. A.* **24**, 2017).

Gas-cock control device. FREDERICK A. GERCICH and WALTER M. BERRY (to Hammer-Bray Co.). U. S. 1,792,488, Feb. 17. Structural features.

Automatic gas shut-off valve. LUTHER D. LOVEKIN (to Kitson Co.). U. S. 1,794,191, Feb. 24. Structural details of a device which shuts off gas flow when water in a tank reaches a certain temp. Cf. *C. A.* **24**, 2335.

Thermostatic valve. EDWARD S. HALSEY. U. S. 1,794,610, March 3. U. S. 1,794,611–12 also relate to valves of the same general type.

Thermostatic device suitable for control of electric circuits. JOSEPH W. MYERS. U. S. 1,793,954, Feb. 24. Structural features.

Thermostatic device for gas ranges. ARTHUR STOCKSTROM and ISAAC V. BRUMBAUGH (to American Stove Co.). U. S. 1,794,329, Feb. 24.

Thermostatic device suitable for humidity indicators, etc. ARTHUR E. KRICK (to National Dry Kiln Co.). U. S. 1,793,809, Feb. 24. Structural features.

Thermostatic valve for hot-water systems, etc. WALTER B. CLIFFORD. U. S. 1,792,891, Feb. 17.

Thermostatic control device for burners such as those of water heaters. HOWARD I. PIATT (to Motor Wheel Corp.). U. S. 1,793,451, Feb. 17. Structural features.

Thermostatic control device for hot water and oil heat-storage systems. C. F. HAMMOND and W. SHACKLETON. Brit. 337,425, July 31, 1929. Structural features.

Chemistry in the vocational high schools of the middle west. MABLE SPENCER. *J. Chem. Education* **8**, 712–6(1931). E. H.

The analytical distillation of gasoline. HAROLD J. TORMEY. *J. Chem. Education* **8**, 679–705(1931).—A lab. exercise for students is described. E. H.

The technic of micromanipulations. E. A. HAUSER. *Rev. gén. colloïdes* **8**, 358–61 (1930); cf. *C. A.* **22**, 1495, 4876; **25**, 1409.—A lecture. A. F.

Reflections on statistical thermodynamics. J. H. COBLYN. *Chaleur et ind.* **9**, 465–76, 527–34(1928); **10**, 194–9(1929); **11**, 31–8, 141–6, 197–205(1930); cf. *C. A.* **23**, 2350; **24**, 2664, 4984. S. L. B. ETHERTON

Simple reduction experiments. E. H. J. MAGER. *Z. physik. chem. Unterricht* **44**, 25–6(1931).—M. describes several demonstration expts.: the reduction of boiling water with Zn dust, the reduction of CuO with (*a*) Fe dust, (*b*) wood charcoal in a porcelain crucible and (*c*) in a gas flame. $CuCl_2$ can be reduced to CuCl by the following treatment: Dissolve a small quantity of $CuCl_2$ in 3–4 cc. concd. HCl and place a wad of Cu wool in the soln. Boil the whole vigorously until the soln. becomes colorless. Pour a portion into water and a white ppt. of CuCl forms; cool the rest and shining crystals of CuCl appear. E. R. SCHIERZ

Gas-volumetric experiments in student exercises. JOSEF KLIMA. *Z. physik. chem. Unterricht* **43**, 265–7(1930).—K. describes a simple and inexpensive app. for collecting gases which resembles the gas-collection part of the Victor Meyer mol.-wt. app. Two burets, one to serve as a leveling tube, are connected at their lower ends with rubber tubing. The one in which the gas is to be collected is fitted with a rubber stopper carrying a T-tube. One arm of the T-tube is connected with a test tube or side-neck test tube which serves as a reaction chamber, the other arm is closed with a pinch clamp. This app. with slight modifications to suit individual cases can be used to det. the H equiv. of metals, the amt. of O in HgO, and for the quant. reduction of oxides (HgO, CuO) or the oxidation of Cu. Diagrams and directions are given. E. R. S.

Evolution of hydrogen sulfide in the Bay of Krasnovodsk. D. ZABRIEV. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. **10**, 58–63. The role of microörganisms is described. V. KALICHEVSKY

Preparation of pure mercury. H. VON STEINWEHR AND A. SCHULZE. *Z. Instrumentenk.* **49**, 566–7(1929).—Hg for use in phys. app. is repeatedly shaken with dil. HNO_3 and then with water; fat is removed by means of petroleum or alc. The Hg is then filtered through a thin leather, previously freed from fat with petroleum, or a Haldenwanger filter tube. It is then distd. in a current of air in a water-pump vacuum in an app. without taps, and preserved in evacuated glass vessels. B. C. A.

Final report of I. M. M. representatives on the Sieves and Screen Committee of the British Engineering Standards Association. S. J. TRUSCOTT AND H. L. SULMAN. *Bull. Inst. Mining Met.* **311**, 9 pp.(1930).—The proposed fine testing sieves are based on a ratio of the fourth root of 2 between linear aperture measurements of consecutive sieves. The American and proposed British sieves will be essentially identical as to aperture but not as to mesh because of the difference in American and British wire gage. ALDEN H. EMERY

A note on gravity separation. R. C. EMMONS. *Am. Mineral.* **15**, 536(1930).—The unsatisfactory nature of gravity sepn. by means of heavy solns. on material in a fine state of division is best accounted for by adhesion, both of grain to grain and grains to air bubbles. This can be eliminated by strong evacuation of the sepg. vessel. A few min. is sufficient. A rapid stratification results when the liquid is allowed to stand, not necessarily under vacuum. A. M. BRANT

The technical preparation of dvi-manganese. J. G. F. DRUCE. *Ind. Chemist* **7**, 75, 79(1931); cf. *C. A.* **24**, 2352.—The history of dvi-Mn (Re), at. no. 75, since its dis-

covery in 1925, its properties and the methods used to sep. it from molybdenite (Brit. Pat. 317,035, *C. A.* **24**, 1943) are given. $KReO_4$ (corresponding to $KMnO_4$) is now being manufactured at a cost of approx. $2.50 per g. A list of references is included.
E. G. R. ARDAGH

The chemistry and the geochemistry of the titanium group. GEORGE VON HEVESY. *J. Chem. Soc.* **1931**, 1–16.—The amts. of these elements in the total mass of the earth are calcd. as follows:

	Ti	Th	Zr
(1) from analyses of terrestrial rocks		14×10^{-7} g./g.	2×10^{-5} g./g.
(*a*) assuming the earth to have an eclogite shell	0.0016 g./g.		
(*b*) assuming a periodotite shell	0.0019 g./g.		
(2) from analyses of meteorites alone	0.0015 g./g.	14×10^{-7} g./g.	3×10^{-5} g./g.
(3) heat equil. considerations		1.3×10^{-7} g./g.	

The geochem. behavior of HfF is similar to that of Zr. When present as a mineral most of the earth's Ti is shown to occur as ilmenite ($FeTiO_3$). J. BALOZIAN

The natural classification of chemical compounds. F. M. SHEMYAKIN. *Z. physik. Chem.*, Abt. A., **152**, 235–44(1931).—Grimm's classification is elaborated. By plotting mol. no. (the sum of the electrons in the atoms of the mol.), sometimes including H and sometimes not, against any property, regularities are revealed. This is true for both org. and inorg. compds. V. F. HARRINGTON

A revision of the atomic weight of calcium. The atomic weight of calcium from sylvite. O. HÖNIGSCHMID AND KÄTE KEMPTER. *Z. anorg. allgem. Chem.* **195**, 1–14 (1931).—If the K_{41} isotope is the radioactive one (cf. *C. A.* **22**, 4356) the disintegration product should be Ca_{41}. The authors attempt to show the existence of Ca_{41} in an old K-bearing mineral (sylvite) by a detn. of the at. wt. of the Ca present. They found 40.195 and 40.226 for Ca in 2 different prepns.; this agrees with a previous report (cf. *C. A.* **24**, 2043) but these high values were due to the presence of Sr. When a correction was made for this they obtained 40.091, in good agreement with 40.085 ± 0.006 found in a redetn. of the at. wt. of Ca in a pure prepn. No indication of Ca_{41} was obtained. J. B. AUSTIN

Behavior of water with change of temperature and with addition of electrolytes as studied by the Raman effect. I. RAMAKRISHNA RAO. *Proc. Roy. Soc.* (London) **A130**, 489–99(1931); cf. *C. A.* **24**, 3436.—Data are presented for ultra-violet and visible Raman bands of pure water at different temps. and of solns. contg. varying concns. of $NaClO_3$, $NaNO_3$ and HNO_3. Increasing temp. shifts the water bands toward the short-wave side; increasing concn. of electrolytes sharpens the water bands. The results are discussed in the light of the assumption that water consists of single, double and triple mols., the relative proportions of each depending on the phys. state of the water. E. J. ROSENBAUM

Electric moment and molecular structure. I. The ethyl esters of mono- and dicarboxylic acids. C. P. SMYTH AND W. S. WALLS. *J. Am. Chem. Soc.* **53**, 527–39 (1931); cf. *C. A.* **24**, 1554.—The dielec. consts. and ds. of the Et esters of a no. of mono- and dicarboxylic acids were measured in C_6H_6 soln. These measurements together with the n_D^{20} for the pure substances were used to calc. the elec. moments of the mols In the moments of the Et esters of the monobasic fatty acids there is a slight decrease with increase in the size of the mol., analogous to the decrease in ionization const. The relative positions of the —COOEt group in the mol. do not affect the moment greatly, because of rotation around the bonds. There is no difference in moment between the long- and short-chain esters, because the long-chain mols. have extended structures, which do not bend in small external elec. fields. **II. Tertiary butyl and triphenylmethyl chlorides and alcohols.** C. P. SMYTH AND R. W. DORNTE. *Ibid* 545–55.—The dielec. consts. and ds. of solns. of *tert*-Bu and Ph_3C chlorides and alcs. in C_7H_{16} or C_6H_6 were detd. over varying ranges of temp. The data were used to calc. the polarizations and elec. moments of the mols. The polarizations show that the branched C chain of the *tert*-Bu group has no greater screening effect than the straight chain of the *n*-Bu group, but the Ph_3C group has a greater effect. The results are explained by a theory of induced moments. The moments increase from the *n*- to the *sec*- to the *tert*-compd. because of the increase in the no. of C atoms subjected to the inductive influence of

the principal dipole. The moment of the *iso*-compd. is the same as that of the normal if the branch in the chain is at least 2 C atoms away from the halogen, because only these 2 C atoms are affected by the principal dipole. H. W. LEAHY

Superstructure and magnetic susceptibility in the system: copper–gold. H. J. SEEMANN AND E. VOGT. *Ann. Physik* [5], **2**, 976–90(1929); cf. *C. A.* **24**, 5196.—The variation of diamagnetic susceptibility with concn. was measured for the Au-Cu mixed-crystal series. Alloys of the compns. Cu_3Au and CuAu in certain circumstances exhibit superimposed structure lines consistent with a regular arrangement of the constituent atoms; *e. g.*, the corners of the elementary cube may be occupied by Au atoms and the face centers by Cu atoms. The relation between susceptibility and the appearance of superstructure was detd. for alloys of the compns. Cu_3Au and CuAu. For the former an increase and for the latter a decrease in diamagnetic susceptibility accompany the production of regular at. distribution in the lattice. Control expts. on alloys differing in compn. from the whole-no. ratios indicated no difference in susceptibility for quenched and slowly cooled specimens. No explanation is available for the difference in sign of the effect with Cu_3Au and CuAu. B. C. A.

Magnetic measurements on rhenium. W. H. ALBRECHT AND E. WEDEKIND. *Naturwissenschaften* **19**, 20–1(1931).—Samples of Re and of K perrhenate having less than 0.01% impurity in the form of Ca and U were measured. Re gave at 18° a sp. susceptibility $\chi = +0.046 \times 10^{-6}$ (± 0.02); the perrhenate is diamagnetic: $\chi = 0.13$ (± 0.05). The Re value does not lie between those of the neighboring elements Os ($+0.074 \times 10^{-6}$) and W ($+0.33 \times 10^{-6}$). B. J. C. VAN DER HOEVEN

Relationships between the dielectric constant and the optical properties of substances having the sodium chloride lattice. J. ERRERA. *Z. Elektrochem.* **36**, 818–23 (1930).—The total polarization of the alkali metal halides increases with increase of at. wt. of the anion and the cation. By using Spangenberg's values for the electronic polarization, the at. polarization was calcd. The proportion of the total dielec. const. due to at. vibrations is decreased as the at. no. of the anion is increased, and in the case of the bromides and iodides with increase of at. no. of the cation. There is an irregular variation in the chlorides and fluorides. The factor p of the infra-red term of the dispersion formula can be detd. by comparing the characteristic infra-red frequencies calcd. by the dispersion formula from the observed values of the dielec. const. with those calcd. by Born by the theory of electrostatic cohesion. The infra-red branch of the dispersion curve can also be calcd. L. L. QUILL

Action of nitric acid on benzoic acid in magnetic and in electrostatic fields. R. H. CLARK AND R. M. ARCHIBALD. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 121–4(1930); cf. following abstr.—The action of HNO_3 on benzoic acid was carried out at 20° in a magnetic field of 23,000 gausses per $\pi/4$ sq. cm. The products of the reaction did not vary appreciably from those obtained outside the magnetic field. J. W. SHIPLEY

Addition of hydrogen bromide to allyl bromide in a magnetic and an electrostatic field. R. H. CLARK AND K. R. GRAY. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 111–4 (1930).—The effect of a magnetic field on the reaction of HBr and allyl bromide in glacial AcOH decreases the yield of trimethylene bromide. For propylene bromide $n_D^{20} = 1.51904$ and for trimethylene bromide $n_D^{20} = 1.52292$. J. W. SHIPLEY

Further investigation of the two electromers of 2-pentene. R. H. CLARK AND E. G. HALLONQUIST. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 115–9(1930); cf. preceding abstr.—The 2 electromers of 2-pentene were synthesized and some of their phys. properties detd. Neither a magnetic nor an electrostatic field had any effect upon the addn. products obtained with HBr on the metastable 2-pentene. Stable 2-pentene has the following consts.: b. p. 35.8° (755 mm.), n_D^{20} 1.37845, f. p. —149°; metastable 2-pentene has b. p. 36.5°, n_D^{20} 1.37960, f. p. —144°. J. W. SHIPLEY

Sound propagation in gas mixtures. D. G. BOURGIN. *Phys. Rev.* [2], **34**, 521–6 (1929).—Mainly math. Previous results on a single gas and a mixt. of 2 gases (cf. *Phil. Mag.* [VII], **7**, 821–41(1929)) are simplified and extended to a mixt. of any no. of gases. B. C. A.

Calculations on the velocity of sound in nitrogen tetroxide. FRANK VERHOEK AND FARRINGTON DANIELS. *J. Am. Chem. Soc.* **53**, 1186–7(1931).—By using dissocn. data of N_2O_4 detd. by V. and D., the velocity of sound was calcd. and compared with the velocities detd. experimentally by Kistiakowsky and Richards (*C. A.* **25**, 864). The agreement is not much better than with the data of Bodenstein, used by K. and R., but the deviation is nearly const. and the calcd. value is always less than the observed velocity; this may indicate a const. error, either in theory or expt. C. J. WEST

The formation of beams in molecular streaming. P. CLAUSING. *Z. Physik* **66**,

471–6(1930); cf. *C. A.* **24**, 3409.—Formulas are given for the distribution of mols. that stream through a short tube at const. pressure into an evacuated space. The mean free path of the mols. is great compared with the size of the tube and diffuse scattering from the walls of the tube is assumed. In the case in which the length of the tube equals the diam., large deviations from the cosine law occur. G. M. M.

Viscosity, heat conduction and diffusion in gas mixtures. XI. The viscosities of H_2, N_2, CO, C_2H_4, O_2 and their binary mixtures. MAX TRAUTZ AND ALBERT MELSTER. *Ann. Physik* [5], **7**, 409–26(1930); cf. *C. A.* **25**, 10.—The viscosities of H_2, N_2, CO, C_2H_4, O_2 and their binary mixts. were detd. over the temp. range 20° to 280° by measuring the rate of flow through a capillary tube. The results were well represented by the Sutherland formula, $\eta_1/\eta_2 = (T_1/T_2)^{1/2} \times [1 + (C/T_2)]/[1 + (C/T_1)]$, by using the following values for the const. *C:* H_2 84.4, N_2 103.9, CO 101.2, O_2 126.6, C_2H_4 241.4. The isotherms of N_2–CO, N_2–O_2 and CO–O_2 mixts. were practically straight lines. The relation between viscosity and mol. diam. in mixts. is discussed. **XII. Viscosity of gases at high temperatures.** MAX TRAUTZ AND ROBERT ZINK. *Ibid* 427–52.—The viscosities of air, N_2, H_2, O_2, CO_2, SO_2, CH_4, A, Ne and He were measured over the temp. range 20° to 830°. The viscosities of air, N_2, A, O_2, CH_4, SO_2 and CO_2, as well as of HCl and Br_2, are accurately represented by the Sutherland formula. The values of *C* for the different gases are given. This formula fails for H_2, He and Ne below the crit. temps, but the viscosities of these gases are given by the formula $\eta = kT^n/[1 + (C/T)]$ where *n* and *C* have the following values: H_2, $n = 2/3$, $C = 0$; He, $n = 2/3$, $C = 2.5$; Ne, $n = 0.6$, $C = 20$. P. T. NEWSOME

Calculating viscosity and flash point in compounded oils. E. KADMER. *Seifensieder-Ztg.* **58**, 22–3(1931).—See *C. A.* **25**, 805. P. ESCHER

Note on the equation of state explicit in the volume. GEORGE SCATCHARD. *Proc Natl. Acad. Sci.* **16**, 811–3(1930).—The Beattie-Bridgeman equation (*C. A.* **21**, 3146) may be expressed in the form $V/n = (RT/p) + (\beta/RT) + [\gamma/(RT)^2 - \beta^2/(RT)^3]p + [\delta/(RT)^3 - 3\beta\gamma/(RT)^4 + 2\beta^3/(RT)^5]p^2$, in which *n* is the no. of moles and the coeffs. β, γ, δ are functions of the temp. This equation reproduces the exptl. results for less perfect gases less satisfactorily than Beattie's original equation (*C. A.* **24**, 1775). The equation is not accurate at high pressures. J. B. AUSTIN

The specific heat of liquid biphenyl. ROY F. NEWTON, B. D. KAURA AND THOMAS DE VRIES. *Ind. Eng. Chem.* **23**, 35–7(1931).—The sp. heat of liquid Ph_2 up to 300° was detd. by 2 elec. heating methods and by a method of mixts. The 3 methods gave consistent results with an av. value for the sp. heat of $(0.388 + 0.00057t°)$ ±1%. F. H. RATHMANN

The specific heat of biphenyl. H. O. FORREST, E. W. BRUGMANN AND L. W. T. CUMMINGS. *Ind. Eng. Chem.* **23**, 37–9(1931).—The sp. heat of Ph_2 in small temp. intervals from 72° to 203° was detd. by the batch-calorimeter method and from 147.7° to 347° by the flow calorimeter. The sp. heat varies from 0.408 ± 2% at 77.6° to 0.672 ± 2% at 347°. The results differ from those of N., K. and De V. by from −5 to +12% (cf preceding abstr.). F. H. RATHMANN

The necessity of adopting a standard substance for boiling-point and vapor-tension measurements. W. SWIETOSLAWSKI. *J. chim. phys.* **27**, 496–502(1930); cf. following abstr.—After a discussion of work done by others in this field, it is recommended by the Comm. on Physical-Chemical Standards of the International Union of Chemistry that b. p. and vapor tension be detd. simultaneously with the b. p. and vapor tension of water, that a few other liquids be standardized and that dp/dt be detd. G. M. P.

A comparative study of boiling points and vapor tensions of eight standard organic substances. AL. ZMACZYNSKI. *J. chim. phys.* **27**, 503–17(1930).—B. ps. and vapor pressures of 8 compds. were measured between 380 and 2000 mm. pressure. The b. ps. of the substances studied were compared with the b. p. of water by the formula $t_{subs.} = A + Bt_{H_2O} + Ct^2_{H_2O}$, and the coeffs. *A*, *B* and *C* were calcd. dp/dt was calcd. The b. ps. detd. at 760 mm. were: EtBr, 38.386°; CS_2, 46.262°; Me_2CO, 56.131°; $CHCl_3$, 61.152°; C_6H_6, 80.122°; PhMe, 110.606°; PhCl, 131.687°; PhBr, 155.908°. GERALD M. PETTY

The vapor pressure of pyridine. P. A. VAN DER MEULEN AND RUSSELL F. MANN *J. Am. Chem. Soc.* **53**, 451–3(1931).—The vapor pressure of pyridine was detd. by the isoteniscope method. Between −20° and +120° the pressure is given by the formula $\log p = 6.8827 - \frac{1281.3}{t + 205}$ where *p* is expressed in mm. of Hg and *t* in degrees C. P. T. NEWSOME

Systems of four immiscible liquid layers. E. LESTER SMITH. *Nature* **127**, 91 (1931).—An example of the rarely observed phenomenon of 4 immiscible liquid

layers can be produced by using hexane 12 cc., $PhNH_2$ 7 cc., oleic acid 0.5 cc., alc. 1.5 cc. and 0.8 *N* NaOH 10 cc. The alc. is not essential to the system but reduces the time required for sepn. of the layers. An increase of temp. or of electrolyte renders miscible the hexane and $PhNH_2$ layers (first and third from the top), which then form the top layer. H. F. JOHNSTONE

Relation of the liquid to the crystalline state. KEDARESWAR BANERJEE. *Nature* **127**, 92–3(1931).—The origin of elastic heat waves in liquids is elec. and akin to that of lattice oscillations in crystals. From theory and from observations on x-ray diffraction, it is seen that there is a max. in the mol. arrangements in liquids corresponding to the structure of the substance in the crystal state. In a crystal the natural frequencies of a mol. that are responsible for the Raman effect are modified because of the surrounding mols., but on account of the regular arrangement all the mols. are affected in the same manner and the Raman lines are sharp. In a liquid, however, the regularity of arrangement is broken, and there is a broadening of the natural frequencies of the mols. H. F. JOHNSTONE

Loading of metals with gas at high pressure. HANS JELLINEK. *Z. Physik* **66**, 543–57(1930).—After activation, Fe, Pd and Ag take up H_2 and N_2 under high pressures. The phenomenon is studied by means of measurements of the elec. cond. When the gas is taken up by the metal, the resistance increases and falls again when the pressure is removed and the gas is liberated. The resistance for Fe and H_2 increases 8.9% between 0 and 35 atm., but for Fe and N_2 it decreases 4.5% up to 15 atm. and then increases 13.3% from 15 to 30 atm. The increase in resistance and pressure range for other cases are: Pd-H_2, 4.4%, 0-20 atm.; Pd-N_2, 3.8%, 0–25 atm.; Ag-H_2, 13.1%, 0-35 atm. G. M. MURPHY

Measurements with the help of liquid helium. XII. Plasticity of metal crystals at low temperatures. W. MEISSNER, M. POLANYI AND E. SCHMID. *Z. Physik* **66**, 477–89 (1930); cf. *C. A.* **24**, 3687.—The plastic deformation of Zn and Cd crystals on stretching was investigated over the temp. range 1.2 20° abs. The plasticity remains nearly const. A method for transporting and handling liquid He is described. G. M. M.

Dependence of the dissociation temperature of solids on the size of crystal grains. J. KRUSTINSONS. *Acta Univ. Latviensis Kim. Fakultat.* **1**, 273–7(in German 278) (1929); cf. *C. A.* **25**, 447.—Red HgO was sepd. into 4 fractions by sieves and it is shown that the dissocn. temps. of the smallest and largest sizes differ by 6°. If the Thomson formula is assumed to hold, the calcd. surface tension at the gas-solid interface is 1146 dynes/cm. G. M. MURPHY

The conductivity of thin metal foils. LADISLAUS TISZA. *Naturwissenschaften* **19**, 86–7(1931).—The limiting thickness of thin metal foils (by cathodic dispersion) at which their resistance rises sharply (cf. Bartlett, *C. A.* **22**, 2879, Perucca *Ann. Physik* **4**, 252(1930), Braunbek, *C. A.* **24**, 1557) can be derived from the free path of the cond. electrons as indicated by J. J. Thomson. It is assumed that the electrons are diffusely reflected by the surface and thereby lose their forward impulse. The resulting free path is $\lambda' = \lambda d/(d + \alpha)$, in which λ is the free path in compact metal, d the thickness of the film, α a const. of about $1/2$. The crit. limiting thickness is d_o = about $\alpha\lambda$, which agrees with exptl. values ($16\mu\mu$ for Ag at room temp., $\lambda = 50\mu\mu$, Sommerfeld). At low temps. with d_o many times larger (λ longer) the results should be more pronounced and characteristic. The present theory, however, does not account for Braunbek's result on Hg: its d_o value of 200–300μ at —183° is too high. B. J. C. v. D. H

Polar properties of single crystals of ice. J. M. ADAMS. *Proc. Roy. Soc.* (London) **A128**, 588–91(1930).—Photographs are reproduced of single microscopic ice crystals grown under controlled conditions. A short right hexagonal prism, with the height nearly equal to the diam. of the base, is a frequently occurring shape for these small crystals. A no. of specimens give evidence of crystallographic polarity by the appearance of a jut at one end only of the *c* axis when the crystal is brought into an atm. favorable to evapn. Two other types of disintegration, characterized resp by juts at each end and in the middle of the *c* axis, are observed in crystals of the same external form. These 2 types are explained as being due to the 2 possible modes of twinning of a polar crystal on the basal plane. The conclusion that the *c* axis in ice is a polar axis does not necessarily contradict the conclusion reached by Barnes that the (0001) plane must be a plane of symmetry so far as the arrangement of O ions in the lattice is concerned (*C. A.* **24**, 765). It is possible that the asymmetric location of H ions in a non-polar O lattice confers the necessary polarity on the structure as a whole. B. C. A.

Crystal structure of molybdenum trioxide. NORA WOOSTER. *Nature* **127**, 93 (1931).—Laue photographs of crystals of MoO_3 show orthorhombic symmetry. The cell size is $a = 3.93 \pm 0.02$ A. U., $b = 13.91 \pm 0.05$ A. U., $c = 3.57 \pm 0.02$ A. U. There

are 4 mols. of MoO_3 per cell. The space group is O_h^{16}. The crystals were thin plates parallel to (010). H. F. JOHNSTONE

The grating constant of quartz. O. BERGQVIST. *Z. Physik* **66**, 494–8(1930).—The grating const. of a rock crystal was measured in the 1st and 2nd orders with Cu $K_{\alpha 1}$ and Fe $K_{\alpha 1}$. The distance from slit to plate was 622.11 mm.; the slit width, 0.02 mm. The x-ray tube operated at 35 kv. and 5 milliamperes; the exposure time was from 20 min. to 2 hrs. No measurable plates were obtained in the 3rd order in 3 hrs. From the values in the 1st order, the higher-order results were calcd. A correction curve to the wave-length calcns. is given for the anomalous dispersion of quartz. The results are d = 4246.02 X. U., log $2d$ = 3.9290120. G. M. MURPHY

Crystal structure of nickel oxides. O. G. BENNETT, R. W. CAIRNS AND EMIL OTT. *J. Am. Chem. Soc.* **53**, 1179–80(1931).—NiO, prepd. by oxidation of $Ni(OH)_2$ with Cl in alk. soln. and heated at 285°, corresponds to the previously reported structure for NiO, as it is face-centered cubic. If the NiO is not heated above 110°, the compd. is cubic but the edge of the unit cube is 4.64 A. U.; the d. is 4.8, as compared to 6.69 for ordinary NiO, the no. of mols. in the unit cell is calcd. as 4; consideration of the intensities of reflection excludes the face-centered cubic type. There is evidence of further modifications. C. J. WEST

The physical properties of rhenium. C. AGTE, H. ALTHERTUM, K. BECKER, G. HEYNE AND K. MOERS. *Naturwissenschaften* **19**, 108–9(1931).—Several properties of Re were detd. The crystal structure is hexagonal in close packing; consts. a = 2.765 A. U., c = 4.470 A. U., c/a = 1.616, smallest distance 2.765 A. U., atomic radius 1.382 A. U. The m. p. is 3440° abs. (measured in drilled hole), the linear thermal expansion (x-ray method) is 12.45×10^{-6} along the hexagonal axis, 4.67×10^{-6} perpendicular to it (8% accurate). The d. of a highly annealed rod is 20.9 (calcd. 21.4 for at. wt. 186.31 ± 0.02). The fracture strength of a Re wire grown in gas phase, 0.25 mm. diam., 0.03 mm. W core is 50.6 kg. per sq. mm., elongation 24%. The sp. elec. resistance at room temp. is $\rho = 0.21 \times 10^{-4}$ ohm cm. (15% accurate), its temp. coeff. between 0° and 100° is 3.11×10^{-3}; between 0° and 2710°, 1.98×10^{-3}. The ratio of ρ_{2710} is ρ_0 is 6.34. The electron emission between 1900° and 2700° abs. gives for the Richardson equation A = 200 amp. per sq. cm. and degree squared, b = 59,500, corresponding to an exit energy of 5.1 v. B. J. C. VAN DER HOEVEN

Condition magnitudes for water in the range from 10° to 500° and from saturation pressure to 300 atmospheres. M. TRAUTZ AND H. STEYER. *Forschung Gebiete Ingenieurw.* **2**, 45–51(1931).—A high pressure vessel (vol. 1410 cc. at 15° and 1 atm.) was fitted with a heating device, thermoelements and manometer, and placed in a container packed with insulating material. An air space sepd. this container from the outer jacket. The sp. vol. of water was measured in the range 10° to 370° and 150 to 300 atm. Below the crit. temp. the estd. accuracy was about ±0.2–0.4%, and at the crit. temp., ±2–4%. The change in heat content between 10° and 500°, over the range 150 to 300 atm., was measured with an estd. accuracy of ±3%. From the present PVT data, together with values interpolated between 150 atm. and satn. pressure by utilizing the International Skeleton Steam Tables, a series of values were calcd. for (*1*) αC_p, the product of the Joule-Thomson effect and the sp. heat; (*2*) J, the heat content; and (*3*) C_p, the sp. heat at const. pressure. F. D. ROSSINI

Thermal properties of compressed liquid water. JOSEPH H. KEENAN. *Mech. Eng.* **53**, 127–31(1931).—Recent data of Keyes and Smith on compressed liquid sp. vol. measurements and of Osborne, Stimson and Fiock on satd. vapor measurements, have made possible a much more accurate calcn. of the feed-pump work in power plant operation in the higher temp. and pressure ranges. Calcns. are based on the more accurate const.-entropy measurements as compared with the older and less accurate const.-vol. method. Temp.-entropy diagrams are given for ranges up to 700°F. A diagram is given showing a comparison between const.-entropy feed-pump work and const.-vol. feed-pump work for abs. pressures from 0 to 400 kg./cm.^{2}. The differences are small, usually within 2% of the compression work. A. L. KIBLER

Some final values for the properties of saturated and superheated water. FREDERICK G. KEYES AND LEIGHTON B. SMITH. *Mech. Eng.* **53**, 132–5(1931).—Tabulations are given of all available data of the Mass. Inst. of Technology pertaining to the properties of water. The tabulations include the following: vapor pressures between 100° and 374°; dp/dt at satn. between 0° and 370°; sp. vols. of satd. steam between 100° and 370°; sp. vols. of water at satn. pressure between 100° and 374°; d. of water between 100° and 360°; vols. of liquid water under pressure and at different temps.; isometrics of superheated steam between 200° and 400°. The use of an alloy of 18Cr–8% Ni steel increased the accuracy of high-temp. measurements. A. L. KIBLER

Some additional volume data for superheated steam. L. B. SMITH AND F. G. KEYES. *Mech. Eng.* **53**, 135–7(1931).—The temps. at which steam has been measured are extended to 460° by the use of a stainless-steel bomb. Results are given in tables and diagrams. A. L. KIBLER

The vapor pressure of chlorine monoxide. CHARLES F. GOODEVE. *J. Chem. Soc.* **1930**, 2733–7.—The vapor pressures (from 288° abs to 173° abs.), the m. p. and the b. p. of ClO are detd. The plot of log vapor pressures (mm.) against $1/T_{abs.}$ is the straight line: $\log_{10}p = -1373/T + 7.87$. From the vapor pressures the b. p. of ClO is 2.0°/760 mm., which is a better value than that of Goldschmidt (*C. A.* **14**, 29). From the slope of the line the latent heat of evapn. (L_e) is 6200 cals./g.-mol. The m. p. of ClO is detd. from cooling curves as −116 ± 1°. The value of Trouton's coeff. indicates that little or no assocn. of ClO takes place in the liquid state. J. BALOZIAN

The electrical conductivity of amorphous quartz. WALTER GNANN. *Z. Physik* **66**, 436–52(1930); cf. *C. A.* **24**, 5197.—The surface cond. of amorphous quartz cylinders of 1 cm. diam. and 1.2 cm. length is measured as a function of humidity of the air, tension and time. The cond. is strongly dependent on humidity. Up to 20% relative humidity, quartz is a better insulator than amber, but its cond. increases more rapidly with humidity. Immediately after tension is applied, the current is relatively large but drops after a few hrs. to a const. value. The vol. resistance is greater than 6×10^{19} ohm cm. Similar measurements made on Bakelite C show that it is strongly hygroscopic. G. M. MURPHY

Blanc's alumina. N. PARRAVANO. *Mem. accad. Italia, Classe sci. fis. mat. e nat.* **I**, *Chim.* No. 1, 1–27(1930); cf *C. A.* **24**, 4681.—Further study of Blanc's Al_2O_3 reveals powerful adsorbing properties: at 25° it retains 32.5% CCl_4, 18.7% C_6H_6, 18.2% CS_2 and 17.9% Mc_2CO. It is anisotropic; a diffraction spectrum appears only after mol. rearrangement, which occurs at 180° to 670°, depending on exptl. conditions. This change is accompanied by a crowding of the atoms in the space lattice, which is probably the source of the heat developed in the process. X-ray analysis also shows that this second form passes into a third, corundum, above 950°; this reaction is also an exothermic one accompanied by further crowding of atoms in the lattice. This opinion is strengthened by the fact that the corundum form, is not a catalyst because it will not dehydrate EtOH, while the other forms, whose atoms are further apart, have strong catalytic powers. A summary of the previous work on this substance is included. A. W. CONTIERI

Gradual transition in crystalline sodium nitrate. F. C. KRACEK AND E. POSNJAK. *J. Am. Chem. Soc.* **53**, 1183–4(1931).—$NaNO_3$ exhibits a gradual transition which ends at approx. 275°; the properties of the crystals alter reproducibly over a range of temps. rather than suddenly at a definite transition pt. The coeff. of expansion is nearly const. to about 150°, then it gradually increases to a peak value near 275°, followed by a rapid decrease to a normal value beyond 280°. The heat absorption on heating likewise gradually increases to a max. at 275.5°, while on cooling the heat evolution begins at about 275°. Other changes are noted. C. J. WEST

Calorimetric determinations of heats of adsorption. Adsorption of sulfur dioxide by wood charcoal. A. MAGNUS, H. GIEBENHAIN AND H. VELDE. *Z. physik. Chem.*, Abt. A, **150**, 285–94(1930).—The integral heats of adsorption of SO_2 by coconut charcoal were measured over a wide range of concn. (0.05–68 mg. of SO_2 per g. of charcoal). With increase in the amt. adsorbed there is a slow, regular fall of molar heat of adsorption. Differential heats of adsorption were measured by allowing about 0.12 mg. of gas per g. of adsorbent to be adsorbed on the already more or less charged charcoal. A marked discrepancy appears between the curves for integral and differential heats of adsorption, and this is explained by the slow establishment of equil. in the crevices on the surface of the adsorbent. B. C. A.

Adsorption influence, activity and solvation in salt solutions. P. P. KOSAKEVICH AND N. A. ISMAILOV. *Z. physik. Chem.*, Abt. A, **150**, 295–309(1930).—The adsorption by charcoal of PhOH in aq. soln. and of BzOH in MeOH or EtOH soln. is increased by the presence of the chlorides or bromides of Li, Na or K. In aq. soln. the relative effects of the cations are in the order Na > Li > K and those of the anions Cl > Br. In MeOH the same order is observed for the anions, but this order is reversed in EtOH. The salts raise the activity of the substance adsorbed, providing a means of calcg. the relative activities of the latter from adsorption measurements. On the assumption that the neutral salt effect is due to solvation, values are obtained from adsorption measurements in good agreement with those calcd. from the influence on soly. B. C. A.

The work of the International Bureau of Physical-Chemical Standards. IV. Study of the physical constants of twenty organic compounds. J. TIMMERMANS AND MME. HENNAULT-ROLAND. *J. chim. phys.* 27, 401–42(1930); cf. *C. A.* 22, 4024.—A continuation of work previously reported, carried out with the same precision. The following results were obtained:

	B. p.	M. p.	$d_0°$	$d_{15}°$	$d_{20}°$	$n_{He\ yellow}^{18}$	$\eta_{18}°$

[1] $t = 25°$

For most compds. *n* is also given for He red, green, and violet, and for Hα, Hβ and Hγ; values for mol. refraction are also given for Hβ and Hγ. Extensive summaries are given of values obtained by previous workers. GERALD M. PETTY

Density of glycine. R. C. HOUCK. *J. Am. Chem. Soc.* 52, 2420(1930).—Contrary to previous statements, glycine has d_4^{50} 1.575. B. C. A.

The adsorption time and its measurement by means of diffusion experiments. P. CLAUSING. *Ann. Physik* [5], 7, 489–520(1930).—Previous work on the av. life of the mol. on the adsorbing surface is reviewed. The work of Langmuir, Holst and Becker is considered. In the theoretical discussion the following problem is treated as one of diffusion. *Ibid* 521–68.—The app. used for measuring the adsorption time (av. life on the surface) involved the measurement of the time of flow of a gas through a capillary

tube at low pressure and low temp. Pressure changes were followed with an ionization manometer. For A on glass, the av. life was 75×10^{-6} sec. at 78°K. and 3.1×10^{-5} sec. at 90°K. The adsorption time of N_2 on glass was of the same order of magnitude as that of A. For Ne on glass between 78° and 90°K., the adsorption time was 2×10^{-7} sec. P. T. NEWSOME

The adsorption of gas mixtures by silica. E. C. MARKHAM AND ARTHUR F. BENTON. *J. Am. Chem. Soc.* 53, 497–507(1931).—The adsorption of each gas in binary mixts. of CO and O_2 was measured at 1 atm. and temps. of 0° and 100°, and in mixts. of CO_2 with CO and with O_2 at 100°; the isotherms of the sep. gases were detd. at the same temps. Adsorption values calcd. for the mixts. on the basis of a simple extension of Langmuir's theory of adsorption agree fairly well with observed values for mixts.of CO and O_2. In mixts. contg. CO_2, however, the observed values are not only larger than the calcd. but often exceed the adsorptions found in the absence of the second gas; this is tentatively explained as due to some kind of mutual interaction between the 2 kinds of adsorbed mols. P. H. EMMETT

Adsorption and base exchange. P. G. NUTTING. *J. Wash. Acad. Sci.* 21, 33–6 (1931).—A qual. discussion of adsorption from solns. and of some naturally occurring adsorbates. P. H. EMMETT

Phenomena of adsorption and protection in complex colloidal media. CHARLES MARIE AND N. MARINESCO. *Compt. rend.* 192, 92–4(1931).—The dielec. consts. of aq. solns. of gelatin, glycine and *l*-leucine are higher than that of water; this indicates high elec. moment. Aq. suspensions of C also give higher values than water, which are attributed to induced polarity. When suspensions of C are mixed with solns. of the above compds., however, the dielec. const. becomes lower than that of water, partly because of the removal of free dipoles from the system by adsorption and partly because of the effect of the adsorbate in reducing the field-induced moment of the C particles, *i. e.*, protection of the C. The addn. of gelatin to amino acid solns. also reduces the dielec. const.; this effect is attributed to mol. assocn. or to condensation of dipoles by the gelatin, not to adsorption. Thus the type and amt. of protective colloid required may be detd. by studying the dielec. const. K. V. THIMANN

Rigidity of adsorption layers. D. TALMUD, S. SUCHOVOLSKAYA AND N. LUBMAN. *Z. physik. Chem.*, Abt. A, 151, 401–12(1930).—Measurements of the rigidity of the layer at the air-soln. boundary of solns. of org. acids, in both water and dil. HCl, were made by the method of Rohde (*Ann. Physik* [4], 19, 935 (1906)). The results are presented in support of T.'s theory according to which the rigidity of the layer reaches a max. before it becomes satd. W. L. HILL

Monomolecular films on water and on mercury. I. Superficial films on water. L. FAHIR. *J. chim. phys.* 27, 471–95(1930).—An app. is described for making films on the surface of water. The surface tensions of superficial solns. and of monomol. films of oleic acid, myristic acid, and cetyl alc. were measured at various temps. and time intervals. The data are presented in graphical and tabular form, and the values are approximated by math. formulas. Calcd. mol. dimensions agree well with results obtained by spectrography and with x-rays. The change from surface soln. to surface film depends on the temp. **II. Superficial films on mercury.** *Ibid* 587–603.—An app for studying films on Hg is described. The surface tensions of films of oleic, lauric, myristic, palmitic and stearic acids, cetyl alc., triolein and benzyl benzoate on Hg were measured. Films of oleic acid have twice as high a satn. pressure on Hg as on water. The mol. dimensions were calcd. and values developed for the energy of a dipole in the elec. field of water and of Hg, and for the total energy of the film. GERALD M. PETTY

Formation of streamers in sedimentation. C. E. MARSHALL. *Nature* 126, 94 (1930).—The centrifugal method previously described (*C. A.* 24, 2356) for detg. particle size is not invalidated by the formation of streamers. B. C. A.

Technic of extracting liquids that form emulsions. WALTER WEINBERGER. *Am. J. Pharm.* 102, 594–5(1930).—One of the following methods usually succeeds in breaking emulsions that may form in extg. a solute from a liquid solvent by means of a second solvent immiscible with the first: (1) addn. of excess of the solvent in the dispersed phase, (2) addn. of a third solvent miscible with each of the other 2, (3) destruction of the emulsifying agent, (4) salting out, (5) filtration, (6) heating, freezing or electrolyzing, (7) centrifuging. If the emulsion is present only as a broad layer at the interface between the two phases it is best to draw off the emulsion separately and break it. Examples: (1) If the emulsion is one between ether and water, take a small sample in a test tube and add successive portions of water; if unsuccessful, take a second sample and add ether. (2) A small addn. of alc. often breaks an emulsion between ether and water. (3) An emulsion stabilized by soap may be broken by adding acid.

HCHO breaks emulsions stabilized by proteins. (4) Anhyd. Na_2SO_4, $(NH_4)_2SO_4$, or $CaCl_2$ often salts out emulsifying agents. (5) Filtration breaks emulsions stabilized by flocculent ppts. W. G. GAESSLER

The dielectric constants of complex colloidal systems. Adsorption by micelles in solution. Dielectric origin of the adsorptive forces. CHARLES MARIE AND NÉDA MARINESCO. *J. chim. phys.* **27**, 455–70(1930); cf. *C. A.* **21**, 3806; **22**, 4385.—Tables and graphs are given which show the variation of dielec. const. with concn. of suspensions of C in water and in gelatin, of isoelec. gelatin, of *l*-leucine and C, and of glycine, gelatin and C. The phenomenon of protection was sepd. from the phenomenon of assocn. in complex mixts. Dielec. analysis permits the arbitrary choice of a protective colloid, and a detn. of the quantity necessary to protect an unstable colloid. GERALD M. PETTY

Formation of spirals by chemical precipitation. R. E. LIESEGANG. *Naturwissenschaften* **18**, 645–6(1930).—The spiral structures found by Schikorr (*Ibid* **18**, 376(1930)) are simply varieties of the ordinary Liesegang rings. A photograph showing the occurrence of these spirals in Ag_2CrO_4 pptd. in gelatin is reproduced. B. C. A.

Study of E. Fischer's polypeptides with x-rays. FRITZ V. LENEL. *Naturwissenschaften* **19**, 19(1931).—X-ray photographs were made of 4 Fischer prepns: I *dl*-leucyltetraglycylglycine, II *l*-leucyloctaglycylglycine, III *l*-leucyltriglycyl-*l*-leucyloctaglycylglycine and IV *l*-leucyltriglycyl-*l*-leucyltriglycyl-*l*-leucyloctaglycylglycine. "Mark" tubes of 0.8 mm. diam., 10 to 20μ wall were used to contain the substances in a Debye-Scherrer camera of 117.7 mm. diam., Cu *K* rays, 10 hrs. exposure, 10 to 12 amps., 35 kv. Rings at various angles were found. In the last 3 prepns. a recurring ring at $\vartheta = 10°36'$ indicates a crystallographic distance of 4.07 A. U. between polypeptide chains (4.65 and 5.20 for silk). For I a distance of 3.15 A. U. is found that is probably unrelated to the 3.5 A. U. of the av. of glycylalanyl (K. H. Meyer *C. A.* **23**, 3721). A pos. result of the study is that the polypeptides are cryst. B. J. C. VAN DER HOEVEN

Solubility of salts in ethylene glycol and in its mixtures with water. H. M. TRIMBLE. *Ind. Eng. Chem.* **23**, 165–7(1931).—Tabular and graphical data are presented for the soly. at 30° of KI, KBr, $CuSO_4.5$ aq, K_2SO_4, NaCl and KCl in ethylene glycol, in water and in mixts. of the 2 solvents. The relative order of solubilities is much the same. Metathetical reactions, and reactions in which one metal displaces another, took place readily in ethylene glycol solns. GERALD M. PETTY

Influences acting upon solubility. VII. The couples: thiourea-antipyrine and caffeine-antipyrine. E. OLIVERI-MANDALÀ AND L. IRRERA. *Gazz. chim. ital.* **60**, 872–7(1930); cf. O.-M., *C. A.* **21**, 1395.—The cryoscopic measurements were carried out by the method of Bargellini (*C. A.* **14**, 488). The expts. show that (1) the solubilities of thiourea (I) and of caffeine (II) in water increase greatly with addn. of antipyrine (III); (2) the temp. coeffs. of soly. and the thermal effect, *q*, calcd. by the isochore formula of van't Hoff are not reliable criteria of the presence of mol. complexes in water; and (3) the cryoscopic method and that based on soly. coeffs. at different temps. often give different results. The following data give the soly. (mols. per l.) in water of I and of II at the temps. shown: **I**; 10°, 1.1176; 15°, 1.383; 20°, 1.544; 25°, 1.759; **II**, 15°, 0.058; 25°, 0.100; 35°, 0.167. The soly. values and soly. coeffs. of the I-III and II-III solns. are given in more extensive tables, which should be consulted for details. C. C. DAVIS

Critical solution temperatures of systems of sulfur dioxide and normal paraffins. W. F. SEYER AND E. TODD. *Ind. Eng. Chem.* **23**, 325–7(1931).—It was found in study of the systems of SO_2 and butane, hexane, octane, decane, dotriacontane, duodecane and tetradecane that the crit. soln. temp. is a function of the mol. wt. of the hydrocarbon. The amt. of hydrocarbon sol. in SO_2 at its b. p. is comparatively small. D. F. BROWN

Temperature of maximum density of aqueous solutions. Deviations from the law of Despretz. NORA GREGG-WILSON AND ROBERT WRIGHT. *J. Phys. Chem.* **35**, 624–8 (1931); cf. *C. A.* **13**, 923.—Previous expts. with dil. solns. supported the law of Despretz, but on investigating more concd. solns. deviations were found which seem to depend upon 3 factors, *viz.*, lowering of the f. p., increase in the coeff. of expansion and the d. of the soln. In general with more concd. solns. the temp. of max. d. is lower than the f. p. The law of Despretz holds only for dil. solns. H. W. LEAHY

The role of chemical impurities in the fluctuation of heats of solution of monotropic salts. K. P. MISHCHENKO. *Z. Elektrochem.* **36**, 777–82(1930).—In order to det. the source of the variations in the heat of soln. of KCl (of the order of ±1 percent) very accurate measurements were made with an adiabatic calorimeter (cf. *C. A.* **24**, 4694) devised by L. and M. Other solid modifications of KCl were considered as a possible

source of the variations and for this reason certified samples of KCl from two sources were used after drying at 300°; after fusing; and with no previous treatment. Excellent agreement at 25° of 6 detns., with the high —4200 cal. and the low —4194 cal., gave an av. value of —4196 cal. as the integral heat of soln. of KCl to KCl.200 H_2O and indicated that other modifications were not the source of error. A sample of KCl of analytical grade gave consistently low results—about —4175 cal. but after one recrystn. it gave —4184 cal. This indicated the source of error and when addn. of small amts. of $CaSO_4$ to the certified samples gave correspondingly low results the proof seems conclusive ODEN E. SHEPPARD

Heats of dilution of uni- and multivalent strong electrolytes at great dilution. E. LANGE AND J. MONHEIM. *Z. Elektrochem.* **36,** 772–7(1930).—The exptl. integral heats of diln. recently made available by Lange and collaborators (cf. *C. A.* **22,** 346; **24,** 4694; **23,** 1562, etc.) for 14 1-1 type, 2 2-2 type and 4 2-1 type salts are collected, plotted, and discussed in a more extended fashion (cf. Lange and Meixner *C. A.* **24,** 1018). With 1-1 type salts with same cations the initial exptl slopes, *A*, which correspond to "*a*" values (apparent ionic diameters) are larger the smaller the radius of the opposite ion. This relation is valid for the 2-1 type salts investigated. $A_{MgCl_2} > A_{CaCl_2} > A_{SrCl_2} > A_{BaCl_2}$. However, the measurements available indicate the reverse condition in regard to the 2-2 type salts as far as is indicated by $CaSO_4$ and $MgSO_4$. Possibly this is due to the fact that Mg ion has a greater parameter due to the extent of hydration. Possibly in all cases the temp. change of the parameter is a factor individual for each ion. This may also play a part in the explanation of neg. slopes in heats-of-diln. curves. ODEN E. SHEPPARD

Rotation dispersion of optically active substances. E. KEESER. *Strahlentherap.* **34,** 574–7(1929).—The circular dichroism and optical activity of various proteins were studied; the curve of the anomalous rotation dispersion of a 5% egg-albumin soln. in presence of Cu sulfate is reproduced. B. C. A.

The theories of the Soret effect. G. S. HARTLEY *Trans Faraday Soc.* **27,** Pt. I, 1–10(1931).—H. reviews the kinetic theories of the Soret effect advanced by van't Hoff, Wereide, Porter and Chapman and points out the error common to all of them, *viz.:* attributing to the solvent only the role of vehicle and carrier of the solute. He obtains independent support for Eastman's theory by basing a treatment on the assumption that a gradient of osmotic pressure produces the same velocity of ion transfer as an elec. field which gives rise to the same force per ion. E. R. SCHIERZ

Note on the use of acetamide as a solvent in cryoscopy. E. CHERBULIEZ AND G. DE MANDROT. *Helv. Chim. Acta* **14,** 183–6(1931); cf. *C. A.* **25,** 2159.—Acetamide (I) was the only suitable solvent found for detg. the mol. wt. of certain disintegration products of casein. Previously detd. (cf. Bruni and A. Manuelli, *Gazz. chim. ital.* **35,** 1448(1905)) values of the cryoscopic *K* for I (3630 with urethan, 3330 with naphthalene and 3740 with biphenyl) disagreed so widely that new values were detd. with acetanilide, where *K* = 4861 at 0.897% concn., 4223 at 1.877% and 4177 at 2.520%; hippuric acid, where *K* = 4543 at 1.346% concn., 4240 at 2.418%; and diketopiperazine, where *K* = 4885 at 0.507% concn. and 4790 at 0.866%. The values of *K* decrease with increase in concn. but at the same mol. concn. of each solute the values check within 5%. The detns. were made with pure, dry I in Beckmann tubes in a paraffin bath (to avoid water vapor) placed in a const.-temp. enclosure at 78° maintained by boiling AcOEt. I kept in a desiccator does not melt at a const. temp. and in a week the m. p. drops several degrees, indicating 2 modifications of I. Despite these facts results agree well when values of *K* are used depending on the concn., and the results are considered valuable in the work under consideration. ODEN E. SHEPPARD

Solvents. T. H. DURRANS. *J. Oil & Colour Chem. Assoc.* **14,** 65–80(1931).—The phys. chemistry of solns. with particular reference to *lacquer solvents* is discussed. G. G. SWARD

Studies on the porous-disk method of measuring osmotic pressure. F. T. MARTIN AND L. H. SCHULTZ. *J. Phys. Chem.* **35,** 638–48(1931).—The porous-disk method of Frazer and Patrick (cf. Townend, *C. A.* **23,** 752) for directly measuring osmotic pressure was modified and applied to dil. solns. of KCl with sufficient success to justify further work on it. Errors in the results were traceable to unequal temps. within the app. and therefore suggest refinements in construction. Distn. was obtained at will in either direction with relation to the disk, which had not been possible in previous work. H. W. LEAHY

Fractional precipitation. V. The influence of foreign substances in the crystal lattice. OTTO RUFF. *Z. anorg. allgem. Chem.* **195,** 60(1931).—Additional literature reference for a previous article (cf. *C. A.* **24,** 2030). J. B. AUSTIN

Free energy of formation of thallium amalgams. CHARLES EDWIN TEETER, JR. *J. Am. Chem. Soc.* **53**, 1180–1(1931). C. J. WEST

The deposition series of metals in fused salts. GIOVANNI DEVOTO. *Atti III congresso naz. chim. pura applicata* **1930**, 322–30.—From existing data, the free energy of formation at 700° and at the m. p. was calcd. for *halides* of the *alkali* metals, *alk. earth* metals and a few other metals such as *Mn, Cu, Co* and *Tl*. The potential relative to H at 700° was calcd. for a number of metals. J. B. AUSTIN

The diffusion of salt ions into aluminum. J. CICHOCKI. *Compt. rend.* **191**, 841–2 (1930); cf. *C. A.* **23**, 5099.—An Al tube, 2 mm. inside diam., and 4 mm. outside diam. was filled with $NiCl_2$, and drawn to 0.83 mm. outside diam. It was placed concentrically with a tube of Al in a larger glass tube, and the system was evacuated. At 600° and 80 v., a thermionic current was obtained, which rose to a max. of about 2.3×10^{-7} amp. in 60 min., followed by a rapid decrease. No neg. emission was obtained. The thermionic current was due to an absorption of the salt by the metal. G. M. P.

The apparent dissociation constants of phenylalanine and of dihydroxyphenylalanine and the apparent free-energy and entropy change of certain amino acids due to ionization. SADAICHI MIYAMOTO AND CARL L. A. SCHMIDT. *J. Biol. Chem.* **90**, 165–78 (1931).—The apparent dissocn. consts. for *dl*-phenylalanine and *dl*-3,4-dihydroxyphenylalanine were detd. Values for the apparent standard free-energy change for the ionization of those naturally occurring amino acids for which apparent dissocn. consts. are available were calcd. Values for ΔS, the apparent change in entropy of the system due to ionization, were calcd. for alanine, glycine, arginine, histidine, lysine, aspartic and glutamic acids and diiodotyrosine. Calcns. were made which show that no appreciable error results when concn is used instead of activity in calcg. the primary dissocn. const. of aspartic acid and of glutamic acid. P. H. EMMETT

Electrolytic water as acid. R. SAXON. *Chem. News* **142**, 49–50(1931).—A method of prepg. H is described. H is liberated rapidly from pure water at a Cu anode with a potential of 200 v. Since the cathode becomes plated with Cu a Cu cathode is desirable also. No gas appears at the cathode. White CuOH is formed first; this turns through a light-blue to a green hydroxide. Electrolytic reactions cannot be represented accurately by chem. equations. The reaction in question is explained by a rotation of the charged element H within H_2O groups from the position OHH^+ to the position ^+HOH under the influence of the charges on the electrodes. The stage of the white hydroxide is formulated as $H)OHH^+OHH^+ \ldots OHH^+$ (OHCu and the stage of green hydroxide as $HH)OHH^+OHH^+ \ldots OHH^+$(OHOH Cu, in which) represents the pos. and (the neg. electrode. ALLEN S. SMITH

Buffer solutions from secondary sodium phosphate and citric acid. K. H. SLOTTA AND W. FRANKE. *Ber.* **64B**, 452–4(1931).—Buffer solns. prepd. from these 2 salts have a range of p_H 2.2 to 7.4. The values given for the various proportions differ considerably from previous reports. V. F. HARRINGTON

The "drop method" apparatus of Todt for the colorimetric determination of p_H values. I. M. KOLTHOFF. *Chem. Weekblad* **5**, 78–9(1931).—The several shortcomings of this method are pointed out. Buffer solns. are recommended in order to minimize the chances for making errors. J. C. JURRJENS

The use of indicators with two color ranges for the photometric determination of the hydrogen-ion concentration. HANS LINSER. *Biochem. Z.* **230**, 285–9(1931).—The use of an indicator with a single color range is preferable to that with 2 color changes in detg. the p_H by means of the step photometer. S. MORGULIS

The potential of the iridi-iridochloride electrode. HENRY TERREY AND HERBERT C. BAKER. *J. Chem. Soc.* **1930**, 2583–6.—The potential of the iridi-iridochloride electrode was measured, the cell arrangement being: $\overline{Hg} \mid Hg_2Cl_2 + NaCl \mid NaCl + Na_2IrCl_6 + Na_3IrCl_6 \mid Ir$. The electrodes were of (*a*) iridized Ir-foil welded to Pt-Ir wire, or (*b*) iridized glass, the Na_3IrCl_6 concns. being held const. at 0.984×10^{-3} *N* and the Na_2IrCl_6 concns. being varied from 0.874 to 18.482×10^{-3} *N*. The e. m. f. values vary according to: $E = E_o + RT/F \cdot \log_e i/o$, where, i and o are the concns. of Na_2IrCl_6 and Na_3IrCl_6, resp. The heat of oxidation of the iridochloride was calcd. as 5600 cal./mol. It is found that the irido-iridichlorides are correctly represented as being of the "ferro-ferri" type. J. BALOZIAN

The reduction potential of thymoquinhydrone. EINAR BIILMANN AND JYTTE MUUS. *Ber.* **64B**, 310–4(1931).—The prepn. of pure thymoquinhydrone is described. Its potential was measured against quinhydrone. The values were not very const., increasing with time and temp. The e. m. f. against H_2 is at 18° 0.5927 ± 0.0005 v. and at 25°, 0.5866 ± 0.0005 v. V. F. HARRINGTON

The behavior of the modifications and varieties of silica in a stream of chlorine in the presence of carbon. E. GRUNER AND J. ELÖD. *Z. anorg. allgem. Chem.* **195**, 269–87(1931).—The sequence of reactions is shown to be $SiO_2 + 2Cl_2 \longrightarrow SiCl_4 + O_2$; $2C + O_2 \longrightarrow 2CO$ and not the more commonly accepted $SiO_2 + C \longrightarrow Si + 2CO$; $Si + 2Cl_2 \longrightarrow SiCl_4$. The temps. of formation of $SiCl_4$ from SiO_2, Cl and C are 740° from amorphous SiO_2, 1060° from tridymite, 1060° from cristobalite and 1220° from quartz. For various naturally occurring varieties of SiO_2 the necessary temp. is 800–1100°, depending on the degree of aging. The temp. of formation of $SiCl_4$ can be used in the analysis of SiO_2 to det. the amts. of the various modifications present. A. P. SACHS

The influence of the silent discharge on sulfur vapor. ROBERT SCHWARZ AND PAUL ROYEN. *Z. anorg. allgem. Chem.* **196**, 1–10(1931).—The behavior of S vapor at a temp. of 460° in a silent elec. discharge was studied by a dilatometric method. A relative contraction was observed. This is explained by postulating the formation of S_3 (thiozone) mols. E. J. ROSENBAUM

The existence of hyzone. ROBERT SCHWARZ AND PAUL ROYEN. *Z. anorg. allgem. Chem.* **196**, 11–25(1931).—A silent elec. discharge was passed through H at a pressure of 4 cm. Hg and liquid air temp. The decrease in pressure was measured at frequent time intervals. From the amt. of contraction observed and a calcn. of the wall-adsorption of H atoms, it is concluded that the effect is due only to the adsorption of H atoms and that there is no evidence of H_3. E. J. ROSENBAUM

The hydrolysis of acetamide. THOMAS W. J. TAYLOR. *J. Chem. Soc.* **1930**, 2741–50.—The effect of acids (3, 4, 5 *N* HCl, and 4, 5 *N* HBr and H_2SO_4) and bases (*N* NaOH and KOH) on the velocity of hydrolysis of acetamide (in 0.05 *N* soln.) at 25° is measured, together with the effect of 4 *N* and 5 *N* HCl at 40° and 41°, resp. The salt effects are detd. at 25° with 4 *N* HCl for *N* alkali (Li, Na, K) chloride, 4 *N* HBr for *N* alkali bromide solns, *N* NaOH for 2, 2.5 *N* NaCl, 2, 3 *N* NaBr, and with *N* KOH for 2 *N* KCl, KBr and KI. Curves of the acid normality against the velocity coeffs. at 25° and 50° indicate that for HCl the velocity coeff. is max. when the acid concn. is 3 *N*. A similar max. is shown by HBr, but is not present with H_2SO_4. To explain these max. it is assumed that with acetamide HCl and HBr form complexes ($2CH_3{\cdot}CO{\cdot}NH_2$, HCl and $2CH_3{\cdot}CO{\cdot}NH_2$, HBr, resp.), which do not hydrolyze, while H_2SO_4 does not form such a complex. It is found that with 4 *N* HCl as catalyst, NaCl and KCl accelerate the hydrolysis, while LiCl fails to do so; with HBr, KBr accelerates the reaction, NaBr has no apparent effect, while LiBr represses it. To explain this behavior of salts, the assumption is made that acetamide forms stable complexes with certain salts, which complexes do not hydrolyze. The effect of any salt is the same in bases as in acids. J BALOZIAN

Vapor-phase equilibrium of the simplest cis-trans isomers (dichloroethylene). L. EBERT AND R. BÜLL. *Z. physik. Chem.*, Abt. A, **152**, 451–2(1931).—The *b. ps. of cis- and trans-*$C_2H_2Cl_2$ are 60.14 ± 0.04° and 47.48 ± 0.04°, resp. (purity checked by dielec. precision measurements). An exact *b. p. curve of mixts. of the 2 isomers* was detd. Condensation of the vapor in equil. at 300° yielded 63% of *cis*-$C_2H_2Cl_2$, the thermodynamically more stable form. FRANK URBAN

The melting point in the tungsten–rhenium system. KARL BECKER AND KURT MOERS. *Metallwirtschaft* **9**, 1063–6(1930).—The solidus line for the W Re system was detd. An intermetallic compd., W_2Re_3, m. 3005° and with 2 eutectics one with 50 atomic % Re and m. 2892°, the other with 67 atomic % Re and m. 2822°, were found. C. H. LORIG

The modifications of silver iodide. R. BLOCH AND H. MÖLLER. *Z. physik. Chem.*, Abt. A, **152**, 245–68(1931).—By röntgenographic and microscopic examn. of AgI prepd. by various methods the phase diagram was constructed. There are 3 modifications; cubic (< 135°), hexagonal (135–46°) and "hot" cubic (> 146°). Methods of prepg. both cold forms are given. V. F. HARRINGTON

Phase equilibrium in binary systems with continuous mixed crystals. E. KORDES. *Z. physik. Chem.*, Abt. A, **152**, 161–96(1931).—A simple empirical equation is given for the phase equil. between crystals and liquid, between crystal modifications within continuous crystals and between the anisotropic liquid state and the isotropic. Previous data are used to prove the general applicability of the equation. The value of this equation in geochemistry (the zone formation in plagioclase, the difference between isopolymorphism and boundary miscibility, etc.), is suggested. V. F. H.

Phase-rule studies on metallic thiocyanates. I. The systems $Ba(CNS)_2$–NaCNS–H_2O and $Ba(CNS)_2$–KCNS–H_2O at 25°. VINCENT J. OCCLESHAW. *J. Chem. Soc.* **1931**, 55–60.—The systems $Ba(CNS)_2$–$Na(CNS)$–H_2O (I) and $Ba(CNS)_2$–KCNS–H_2O

(II) are investigated, and the solubilities of NaCNS, KCNS and $Ba(CNS)_2$ in H_2O are detd. at 25°. The ternary diagram of system I shows that no double salt exists at 25° $NaCNS.2H_2O$ is the stable solid phase at this temp. when NaCNS is in equil. with its satd. solns., its transition temp. being 30.3–04° (detd. dilatometrically and thermometrically). In system II $3KCNS.2Ba(CNS)_2.5H_2O$ exists over a wide area. It is prepd. by allowing a soln. contg. the correct proportions of the constituent salts to cryst. at 25°, freeing from mother liquor as much as possible by suction, and drying in air in cold weather. At 25° the soly. in g./100 g. is detd. as 58.78 for NaCNS, 70.89 for KCNS and 62.61 for $Ba(CNS)_2$. J. Balozian

Physical constants of the system methane-hydrogen. F. A. Freeth and T. H. Verschoyle. *Proc. Roy. Soc.* (London) **A130**, 453–63(1931), cf. *C. A.* **25**, 1422. —The pressure range of CH_4 isotherms was extended to 215 atm. The m.-p. curve was detd. The triple point was observed to be −182.46° at a pressure of 8.737 cm. The three-phase curve and one isotherm at −182.5° of the system CH_4–H_2 were detd. E. J. Rosenbaum

Kinetics of chlorine bleaches and hypochlorite solutions. Joseph J. Weiss. *Z. Elektrochem.* **37**, 20–5(1931); cf. *C. A.* **24**, 5589. — The velocity of spontaneous decompn. of alk. hypochlorite solns. by the general reactions $3ClO^- \longrightarrow ClO^-_3 + 2Cl^-$; $2ClO^- \longrightarrow 2Cl^- + 2O$, at const. H-ion concn. is given by $\frac{d[ClO^-]}{dt} = \left\{k_2\frac{f_2^1}{f_2} + k_2'' f_{HOCl}^2 [H^+]\right\}\left\{[OCl^-]_0^2 \left(\frac{1}{[ClO^-]_t} - \frac{1}{[ClO^-]_0}\right)\right\} = k_2\frac{f_2^2}{f_2} + k_2'' f_{HOCl}^2 [H^+] \quad k_{bi}$ Consideration of the F. Foerster tests (*Z. Elektrochem.* **23**, 137(1917); cf. *C. A.* **11**, 2865) and use of the Debye-Hückel theory gives $k_{bim}^F = 1.97 \times 10^{-4} \times 10^{0.704\sqrt{2}[OH^-]} \sqrt{2[OCl^-]} + 1.2 \times 10^{-4}\frac{f_{HOCl}^2}{[OH^-]}$ at 25°, time in days and concn. in mol./l. Consideration of the Kauffmann tests (*C. A.* **19**, 561) gives $k_{bim}^K = (5.1 \times 10^{-4} f_{HOCl}^2/[OH^-])$ in the same units. General kinetics of Cl bleaches, if HOCl or Cl_2O is assumed as the bleaching principle, are set up, and the oxidation mechanism is discussed; with p_H = const. $\frac{d[ClO^-]}{dt} = \{f(F) + k_2'\{f_{HOCl}^2 f_{HOCl}[H^+][ClO^-]^2; \frac{1}{t}\left(\frac{1}{[ClO^-]_t} - \frac{1}{[ClO^-]_0}\right) = \{f(F) + k_2'\} f_{HOCl}^2 k'_{HOCl}[H^+] = k'_{bim}$ For homogeneous reactions $f(F)$ = const. $[R] + k_2'$ (R is the reducing agent). This is compared with the Kauffmann phenolphthalein tests and confirmed. For heterogeneous reactions a form $f(F) = a_1[H^+]^n + a_2$ is discussed, which in general leads to a H-ion concn. for extreme reaction velocity. There is discussed n, a reaction velocity and swelling being assumed for the special case of cellulose bleaching or oxidation, where $k'_{bim.} = f_{HOCl}^2\{b_1\sqrt{[H^+]} + b_k[H^+]\}$. The Clibbens and Ridge tests (cf. *C. A.* **21**, 2192) and theory are discussed for the cases $b_1 = 3.92 \times 10^4$, $b_k = -4.0 \times 10^7$, $[H^+]^{a)}_{max.} = 2.5 \times 10^{-7}$; and $b_1 = 10.4 \times 10^4$, $b_k = -2.2 \times 10^8$, $[H^+]^{b)}_{max.} = 0.6 \times 10^{-7}$ as H-ion concns. of greatest fiber attack. A notable fact for useful application of practical bleaching of cellulose and textiles is that, from the general difference of the n of the fiber and the n of the color to be discharged, a H-ion concn. or interval can be calcd. at which the color to be discharged is attacked rapidly, while the textile or fiber is practically unattacked, which is advantageous as regards bleach loss and textile strength. E. M. Symmes

Influence of the triazo ion in the catalytic action of colloidal platinum on hydrogen peroxide. E. Oliveri-Mandalà. *Gazz. chim. ital.* **60**, 878–82(1930); cf. *C. A.* **24**, 1017.—Colloidal Pt was prepd. by the method of Bredig. Decompn. of H_2O_2 was followed by N detns. with an app. used previously for the catalytic decompn. of HN_3 (cf. *C. A.* **11**, 1608). The molar concns. per l. of the H_2O_2, NH_3 and colloidal Pt were 0.0839, 0.012 and 0.00019, resp. The velocity of decompn. of H_2O_2 is reduced greatly by adding small quantities of NH_3; even traces of NH_3 reduce the velocity about 0.5. The velocity const., K, is not a linear function of the concn. of NH_3. The presence of HN_3 decreases K about 25%. The temp. coeff., K_{t+10}/K_t, is 1.66 to 2. Conclusion: the catalytic decompn. of aq. H_2O_2 follows the logarithmic law: $x = A(1-e^{-kt})$, and the temp. coeff. per 10 degrees is approx. 2, whether NH_3 is present or not. C. C. Davis

Autoxidation of cyclohexene by oxygen. N. D. Zelinskii and P. P. Borisov. *Ber.* **63B**, 2362–5; *J. Russ. Phys.-Chem. Soc.* **62**, 2051–4(1930).—The Lewis-Langmuir

theory predicts the addn. of O to an ethylenic linkage to yield a peroxide without the use of a catalyst. Z. and B. allowed 20 g. of cyclohexene to absorb O. The rate of absorption increased, decreased and became zero after 151 days. 3200 cc. of O, corresponding to *one atom per molecule*, was absorbed. The unchanged cyclohexene was removed by standing in a vacuum desiccator over H_2SO_4 for 3 months, when a tough, resinous, reddish yellow mass remained, which gave the peroxide test with guaiacol resin and ferrous salts, and analyzed for cyclohexene peroxide, $C_6H_{10}O_2$. F. H. RATHMANN

Oxidation of seemingly autoxidizable leuco bases by molecular oxygen. ALBERT REID *Ber.* **63B**, 1920-2(1930). Thionine was reduced by phenylhydrazine to leucothionine and carefully purified by washing with alc., drying and subliming at 190–220° under 0.05 mm M. p. 185°. 2.0 mg. leucothionine in 2 cc. of a molar buffer soln. of NH_4OAc and HOAc, purified in quartz vessels (p_H = 4.5), was shaken in a quartz vessel immersed in a thermostat at 20°, and the rate of absorption of O, noted. From 0.0001 to 0.001 mg. of Cu greatly increased the rate. Replacement of the N of the air by CO greatly reduced the rate both with and without the presence of Cu. Leuco methylene blue gave similar results. It is concluded that the oxidation of these leuco bases is not autoxidation but is catalyzed by traces of such metal ions as Cu, occurring as impurity in even the purest of lab. reagents. F. H. RATHMANN

The catalysis of the reactions between solids. II. The mechanism of the reaction of catalytic stannate formation. SETSURÔ TAMARU AND NOBORU ANDÔ. *Z. anorg. allgem Chem* **195**, 309-20(1931), cf. *C. A.* **24**, 774. If SnO_2 is previously heated to 1150° the stannate formed from the mixt. of SnO_2 and 7CaO without a catalyst at 900° is always small in amt and is independent of the method of prepn. of the SnO_2. The reduction of SnO_2 by H_2 occurs in 2 stages and the further reduction of SnO is repressed by the presence of CaO A new method of *decompose cassiterite for analysis* is proposed, based on the formation of stannate by heating with lime in the absence of air. A. P. SACHS

The decomposition of carbon monoxide in the presence of iron and iron oxides. P. RISCHBIETH. *Z. physik. chem Unterricht* **44**, 22-4(1931). R. describes 2 lecture expts to study the reaction (*a*) $CO \longrightarrow C + CO_2$ and the equil. (*b*) $CO_2 + C \rightleftharpoons CO$ in the presence of Fe and its oxides The gases are passed over heated Fe_2O_3 in a glass tube Even after reduction of the oxide the content of CO_2 in the escaping gases (*a*) remains about const. (50%), indicating the decompn. of the CO in contact with Fe. At 400-500° the equil (*b*) is about 50% CO_2. This catalytic reduction of CO may account for the occurrence of the finely divided C so often met with in the upper regions of the blast furnace. E. R SCHIERZ

The mechanism of iron catalysts in certain oxidations. C. V. SMYTHE. *J. Biol. Chem.* **90**, 251-65(1931).—Ferrous iron present as the unionized pyrophosphate or metaphosphate is shown to oxidize rapidly with O_2 of the air regardless of the acidity of the soln , whereas $FeSO_4$ in similar slightly acid solns. showed no appreciable oxidation. This behavior, as well as the catalytic effect of ferrous and ferric iron in certain org. oxidations, is explained in terms of the electronic structure of the compds. P. H. E.

New methods of organic thermochemistry. M. REBEK. *Arhiv. Hem. Farm.* **4**, 212-21(221 German)(1930).—A report on preliminary expts. to det. the energy content of org compds. J. KUČERA

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

W. ALBERT NOYES, JR.

Masses of the electron, the proton and the universe. A. S. EDDINGTON. *Proc. Cambridge Phil. Soc.* **27,** 15–9(1931); cf. *C. A.* **24,** 1277.—E's "Theory of 137" is developed further. The calcn. of the ratio of mass of the proton to the mass of the electron is given as 1849.6. The "packing fraction" is checked. The no. of protons in the universe is given as 7×10^{78} or 14×10^{78}, depending on whether space is taken as elliptical or spherical. WILLIAM E. VAUGHAN

The quantum theory of zero-point temperature. G. BECK, H. BETHE AND W. RIEZLER. *Naturwissenschaften* **19,** 39(1931).—At 0 abs. all internal motion of a crystal lattice has stopped. All degrees of freedom are "frozen" with the exception of 1 per electron for the Bohr orbits of the electrons. Every electron has (Eddington) $1/\alpha$ degrees of freedom if α is the Sommerfeld fine structure const. Likewise $1/\alpha$ degrees for every proton are present. Hence in order to reach abs. 0 $(2/\alpha)$ —1 degrees of freedom have to be subtracted from a substance per neutron present. If this is equated to 273°, a value of 137 is found for $1/\alpha$ which is considered to agree with a value obtained in a different way. B. J. C. VAN DER HOEVEN

Quantum mechanics of electrons in crystal lattices. R. DEL. KRONIG AND W. G. PENNEY. *Proc. Roy. Soc.* (London) **A130,** 499–513(1931).—Math. The mechanics of electrons in periodic fields of potential are calcd. for an integrable case. The results agree qualitatively with exptl. facts. E. J. ROSENBAUM

Diamagnetism of the free electron. C. G. DARWIN. *Proc. Cambridge Phil. Soc.* **27,** 86–90(1931).—Math. D. shows that the susceptibility of a free electron gas is $2\mu_B^2/3kT$ per electron, where μ_B is the Bohr magneton. WILLIAM E. VAUGHAN

X- and γ-radiation measurement and the new international *r* unit. J. G. STEPHENS *J Cancer Research Comm. Univ. of Sydney* **1,** 222–31(1930).—Radiation is specified clinically by detg. (*a*) the wave length, (*b*) the amt. of energy in the radiation and (*c*) the degree of polarization. The *r* unit, which measures the total ionic charge under certain conditions, is used to express energy in the radiation in terms of the ionization in air. It is suggested that the ionization in liquids such as hexane or light petroleum would be of advantage by reducing the size of app. and giving larger ionization currents B. C. A.

Direct measurement of intensity distribution in molecular beams. J. B. TAYLOR *Z. Physik* **57,** 242–8(1929).—When an alkali metal atom strikes a glowing W wire, it parts with an electron and is reëmitted as a pos. ion. By measuring the no. of pos ions emitted from such a wire in various positions in the path of a mol. beam the no of alkali metal atoms striking the wire per sec. can be detd., and hence the energy distribution in different parts of the beam deduced, with an accuracy of 1 in 10^3. B. C. A.

The production of an intense beam of hydrogen positive ions. LOUIS R. MAXWELL *Rev. Sci. Instruments* **2,** 129–40(1931).—A method was designed for obtaining an intense beam of H_2^+ ions by diminishing the loss of the ions to the walls of the discharge chamber which occurs in the usual method. This is accomplished by placing the discharge chamber in a strong magnetic field in which the direction of the magnetic field is parallel to the direction of motion of the pos. ions. The app. is described. It is capable of producing a pos.-H-ion beam corresponding to currents ranging up to 3 ma. in a region of pressure of 3.3×10^{-3} mm. of Hg. ALLEN S. SMITH

Photographic detection of the asymmetrical angular distribution of twice-reflected electrons. E. RUPP. *Naturwissenschaften* **19,** 109(1931).—Photographs were made of twice-reflected electrons. An electron beam passed through a 0.3-mm. hole and was reflected at 45° on a Au surface. The reflected ray (also at 45°) passed through a 0.1-mm. hole (50 mm. from the point of reflection) with a thin Au foil behind it. The scattered ray is photographed on a plate 450 mm. from the foil. For electrons of 220 kv., diffraction rings were obtained with distinct asymmetry, the rings being weakest on the side away from the original direction of incidence of the electron beam. The asymmetry is not due to the structure of the Au. An Al reflector and foil do not give the same result. B. J. C. VAN DER HOEVEN

Angular scattering of electrons in gases. F. L. ARNOT. *Proc. Cambridge Phil. Soc.* **27,** 73–6(1931); cf. *C. A.* **24,** 1572.—A discussion is given of the error introduced

into expts. on the angular scattering of electrons in gases by a potential at right angles to the electron beam. Calcn. shows that in the previously reported paper the error in all cases was less than 0°17′, which is less than the exptl. error in the detn. of the angles.
WILLIAM E. VAUGHAN

Optical determination of the sphere of action of atoms for electrons. L. S. ORNSTEIN AND A. M. VAN DOMMELEN. *Proc. Acad. Sci. Amsterdam* **33**, 683–9(1930); cf. *C. A.* **24**, 1793, 2668.—The optical method previously described for the detn. of the sphere of action of He atoms is limited to electronic energies above the excitation potential. It is shown that it is possible to extend the measurements below that value with a mixt. of He and Hg. Further it is possible to simplify the method so that intensity measurement is not necessary and the density detn. is sufficient for obtaining the value of the sphere of action.
MARIE FARNSWORTH

The cathode radiation of the sun. H. RUDOLPH. *Naturwissenschaften* **19**, 66 (1931).—From a theory on the daily variation of the earth's magnetism (*Gerl. Beitr. z. Geophysik* **27**, 378(1930)) it is concluded that the N "dust shell" around the earth is negatively charged. This necessitates a strongly neg. corpuscular radiation from the sun and a potential of some 10^{14} v. for this shell. Several conclusions and results are discussed.
B. J. C. VAN DER HOEVEN

Direct photography of ionization in insulating substances. A. GEMANT. *Naturwissenschaften* **19**, 109(1931).—Light-sensitive films in an elec. field are blackened on reaching certain limits of potential. This effect is attributed to ionization; it occurs in gases as well as in liquids and solids. By using photographic paper (semiconductor) as an extension of the plate electrode the structure of insulating substances can be examd. when present between the electrodes. Blackening below the breakdown potential indicates porous structure of the material; ionization and consequent luminescence by either d. c. or a. c. can thus be studied directly. It was found that for a no. of substances only a. c. gives the glow to which the blackening is due.
B. J. C. VAN DER HOEVEN

Photoelectric effect with lead and mercury at low temperatures. J. C. MCLENNAN, R. G. HUNTER AND J. H. MCLEOD. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 3–23(1930).—Measurements of the photoelec. current produced by films of Pb and of Hg when irradiated with ultra-violet light below 3000 A. U. were made down to temps. below the transition point for supercond. The object was to det. whether the emission of electrons from a metal when suitably irradiated undergoes any abrupt modification if the temp. of the metal irradiated is progressively lowered from a point a few degrees above its supercond. transition point to one a few degrees below it. The photoelec. current from Pb and Hg in highly evacuated cells was measured at temps. down to that of liquid H_2. At the temp. of liquid air Pb showed a decrease in the current of about 2% from that of the satn. value of the current at room temp. and a decrease of about 16% at the temp. of liquid H_2. Hg at liquid-air temps. showed large variation with the thickness of the Hg film. Inability to reproduce films of exactly the same thickness made it impossible to draw any conclusions concerning the change in the photoelec. current from Hg at the temps. of liquid air and liquid H_2. The photoelec. current from lead films at the temp. of liquid He and in the superconducting state was slightly less than it was at a few degrees above its transition temp., 7.2°K. No abrupt change took place in the photoelec. emission of electrons from Pb as it was cooled down through its characteristic transition temp.
J. W. SHIPLEY

The action of adsorbed gas films on the photoelectric effect of salts (remark on "The action of Geiger counting chambers"). J. KLAPHECKE. *Naturwissenschaften* **19**, 87(1931).—Water vapor promotes electron emission in a manner similar to that found in Geiger counters by Bosch and Klumb (*C. A.* **25**, 1434) in an investigation of the photoelectric effect of salts. Salts heated *in vacuo* show no photoelectric effect (Werner, *C. A.* **23**, 1295). Salts sublimed in air give a photoelectric current, which increases 10-fold after a short treatment with water vapor. They do not exhibit the same activity as do the same salts with occluded water prepd. from solns. Results on gases other than H_2O are inconclusive.
B. J. C. VAN DER HOEVEN

Cathode sputtering at very low gas pressures. A. GÜNTHERSCHULZE AND K. MEYER. *Z. Physik* **62**, 607–18(1930).—The sputtering of Ag and Cu cathodes in He, Ne, A, H and N has been investigated at pressures so low (generally less than 0.01 mm., in the app. described) that the sputtering is not dependent on the gas pressure. The sputtering electrode, changes in the wt. of which were noted by observing the motion of a spiral spring by which it was supported, was placed near a low-voltage arc consuming 3–5 amp. at 50 v.; it was maintained at a p. d. of 300–1200 v. neg. with respect to the anode of the arc. The amt. of sputtered metal increases with the p. d. applied

to the cathode, and the amt. per unit ion current reaching the cathode increases in the order H, Ne, N, A, at any given cathode potential. No sputtering was observed in He up to the highest p. d. applied, 800 v. The efficiency of the sputtering calcd. as the ratio of heat of vaporization of the metal sputtered to the energy delivered by the ion current ranges from 0.3% in H to 1.3% in A. Data have also been compiled relating to the amt. of gas adsorbed per g. of metal sputtered under various conditions of gas pressure and sputtering electrode potential; the values obtained are in the neighborhood of 0.4 mg. in A, 1.0 mg. in Ne, 0.7 mg. in H and 1–6 mg. in N. B. C. A.

Observation of a particulate emission from the cooled metallic cathode of an electric arc. Georges Laudet. *Compt. rend.* **192**, 202–3(1931). M. McMahon

The dielectric constant and the conductivity of ionized gases. Th. V. Jonescu and C. Mihul. *Compt. rend.* **192**, 343–5(1931).—The values of the cond. and the dielec. const. of electronic gas as detd. previously (*C. A.* **25**, 1440) were about 30 times greater than the calcd. values. The present study indicates that this was due to the assocn. of electrons with mols. to a degree depending on the elec. conditions present in the tube used for the measurements. The results suggest that the long transmission range of short elec. waves of between 10 and 40 m. wave length might be due to a similar assocn. of electrons with mols. in the upper atm. The reflecting power of such an ionized layer would be great for wave lengths between 10 and 40 m. R. H. Lombard

Method of measuring the number of ions in the free atmosphere. Yo Itiwara *Physik. Z.* **32**, 97–106(1931).- The usual type of ion-counting tube does not measure the total no. of ions in the air as some are deflected away from the entrance by the elec. field. Measurements were made of the contour surfaces of equal potential around the end of the counting tube by means of a flame probe. I. discusses and proposes corrections to apply to the data of Hess (*Sitzb. Akad. Wiss. Wien*, Abt. IIa, **138**, 169 (1929)). **Reply.** V. F. Hess. *Ibid* 106. -H. disagrees with I. on several points. T. H. Chilton

Experiments on the entanglement of atoms in a magnetocathodic or cathodic stream. E. Henriot, O. Goche and (Mlle.) F. Dony-Hénault. *J. phys. radium* [7], **2**, 1–11(1931).—Atoms of various substances (W, C, Pt, Na and S) may be entangled in a magnetocathodic or cathodic stream, probably as ions. Once entangled in the electron stream they appear to form an integral part of it in that they are deformed by an elec. or magnetic field in the same way and yield deposits of the particular element used of the same shape as the electronic stream alone. They resist various attempts to sep. them from the electronic stream. However, they may be disengaged from the electronic stream at points of strong curvature of the latter and are obtained as pos. ions. This is brought about by applying an opposite and larger voltage between the plates than that of the electron flow. The electron stream is then bent back to the plate through which it came after reaching a point of great electron density where the curvature of the stream reaches a max., whereas the atoms continue and are deposited on the opposite plate. No satisfactory explanation of the attraction of the electron stream for the atoms is advanced but is thought possible that it is of an electrostatic character. Oden E. Sheppard

The anomalous scattering of α-particles by light nuclei. Eugen Guth and Theodor Sexl. *Z. Physik* **66**, 577–80(1930).—The theory and formulas for the exact calcn of anomalous scattering of α-particles in a Gamov-Gurney-Condon potential field are described. M. McMahon

A new method for the radioactive investigation of pulverized substances. W Sebesta. *Z. Physik* **66**, 598–612(1930).—Because of its great sensitivity the α-ray method is suited to quant. measurement of radioactivity. In the method described a small quantity of pulverized normal material was mixed with the pulverized material to be investigated and the resulting change of gas cond. produced in an α ray counter was measured. Ionization took place in a semi-spherical condenser with circular opening before which the brass dish holding the pulverized material was placed; a quadrant electrometer was used as measuring instrument. The standard material used was Ra Ba sulfate. M. McMahon

An investigation for accomplishing the decomposition of lead atoms. III. A Smits and H. S. Vening Meinesz. *Proc. Acad. Sci. Amsterdam* **33**, 737–48(1930); cf. *C. A.* **19**, 3210; **21**, 855. Marie Farnsworth

Artificial disintegration by α-particles. J. Chadwick, J. E. R. Constable and E. C. Pollard. *Proc. Roy. Soc.* (London) **A130**, 463–89(1931).—Atoms of B, N, Al, F, Na and P were bombarded by α-particles from Po. The protons emitted were recorded by an elec. method, with vacuum-tube amplification. It is assumed that the

protons and α-particles are in definite energy levels within the nucleus. Mass defects have been calcd. and checked against Aston's data (*C. A.* **21**, 3543). E. J. R.

Photoelectric absorption of γ-rays. L. H. GRAY. *Proc. Cambridge Phil. Soc.* **27**, 103–12(1931).—Consideration of the exptl. data has lead G. to the following equation for the photoelec. absorption coeff. per electron (τ) of x-rays and γ-rays: $\log_{10}\tau = \bar{3}.6505 + 1.0\log_{10}\lambda + 0.480(\log_{10}\lambda)^2$. The curve is given. WILLIAM E. VAUGHAN

Capture of electrons by α-particles. H. C. WEBSTER. *Proc. Cambridge Phil. Soc.* **27**, 116–30(1931); cf. *C. A.* **24**, 5617.—The study of the capture by α-particles from Po of electrons emitted from a heated oxide-covered filament was attempted. The ions were recorded with a modified Geiger counter. The exptl. set-up is described in detail. Wholly neg. results were obtained. The disagreement with the work of Davis and Barnes (*C. A.* **24**, 1029) is discussed; no reconciliation is made. W. E. V.

Study of the velocity of disintegration of polonium in various places. L. BOGOYAVLENSKII. *J. phys. radium* [7], **2**, 12–9(1931); cf. *C. A.* **24**, 3143; **24**, 3427.—Three series of expts. on the detn. of the half period were made: in the southern part of U. S. S. R. (42 places), in the region of Leningrad (18 places) and at Dietskoie Selo (3 places). The results vary from 135.5 to 141.1 days. The time seems to depend on the place where the detn. was made. L. D. ROBERTS

The nature of the absorbable radiation accompanying the rays from polonium. IRÈNE CURIE AND FREDERIC JOLIOT. *J. phys. radium* [7], **2**, 20–8(1931).—A more detailed account is given of the work described in *C. A.* **24**, 1792. O. E. S.

Theory of the scattering of short x-rays by molecular hydrogen. H. S. W. MASSEY. *Proc. Cambridge Phil. Soc* **27**, 77–85(1931); cf. *C. A.* **25**, 869.—Theoretical, on the basis of wave mechanics. M. develops a theory which leads to the conclusion that the scattering of short x-rays by mol. H is similar to that for at. H, although the ratio varies with the angle of scattering. There is no agreement with the one set of exptl. values available (cf. Barrett, *C. A.* **22**, 1275, 3581). WILLIAM E. VAUGHAN

Moseley diagram of the ionization voltages of the light atoms and ions. W. BRAUNBEK. *Z. Physik* **63**, 20–9(1930).—The sq. roots of the ionization voltages for the elements and ions of the 1st 3 short periods (to K) are plotted against the at. no. of the element as abscissa, and it is shown that each isoelectronic series (*e. g.*, Li, Be^+, B^{++}, C^{+++} . . .) gives points lying on a straight line, the gradient of these lines being const. in each period. The only point deviating appreciably is that corresponding with Cl^+, and for this ion the ionization voltage of 22.2 v. is predicted instead of the provisionally accepted value of 18.32 v. It is shown that this means that a linear relation exists between the screening nos. and the atomic no. Z in an isoelectronic series, although in the 1st period (H and He) the screening no is independent of the nuclear charge. It is shown that s decreases with increase in Z in an isoelectric series, contrasted with the x-ray terms, in which s increases with increase in Z. A slight concavity in the lines of the Moseley diagram points to a decrease of s with Z which is not exactly linear, the concavity being greatest in the 2nd period and not observable in the 1st period. On this basis values for the ionization potential of the ions Li^+, Be^{+2}, B^{+3}, C^{+4} are extrapolated from the known value of s for He, complete linearity being assumed. These values agree to within 1% with the values calcd. by Hylleraas (*C. A.* **24**, 1285) by means of wave mechanics, which agree very exactly with the unpublished measurements of Edlén and Ericson (cf. *C. A.* **24**, 1575). The equation of Hylleraas is shown to predict a slight decrease of s with increase in the above-mentioned series. B. C. A.

Satellites of the $K\beta_1$ line of elements from iron to zinc. SUEKICHI KAWATA. *Mem. Coll. Sci. Kyoto Imp Univ.*, Ser. A, **13**, 383–7(1930).—In the course of expts. to det. the relative position of the absorption edge and the $K\beta_2$ line for the elements from Fe to Zn several new satellites have been found on the short side of $K\beta_1$ and $K\beta_2$, which seem to correspond to β'' and β''' observed by Druyvesteyn for elements of lesser at. no. than that of Fe. Wave-length tables are presented. The application of the theories of Druyvesteyn and Beuthe as to the origin of these lines is discussed but no definite conclusion is reached. C. J. HUMPHREYS

X-rays in the service of chemistry and industry in 1931. GEORGE L. CLARK. *J. Chem. Education* **8**, 625–39(1931). E. H.

Experimental study of the absorption formula of x-rays. II. MATAKICHI ISHINO AND SUEKICHI KAWATA. *Mem. Coll. Sci. Kyoto Imp. Univ.*, Ser. A, **13**, 375–81(1930); cf. *ibid* **10**, 311(1927).—The relation of the true g.-atomic absorption coeff., $\tau/\rho A$, to the at. no., Z and to the wave length has been studied for a no. of elements by the method described in the previous paper (*C. A.* **22**, 3096). From a study of the data thus obtained it seems right to conclude that the fluorescent absorption of x-rays as a function

of λ and Z does not obey such a simple law as given by $\tau/\rho A = c\lambda^p Z^q$, in which c, p and q remain const., but that it must be connected by a more complex relation. Also, if it is to be expressed by the above formula, the constancy of p and q should hold only in a restricted region, and, in the general case, they should depend somewhat on λ and Z. C. J. HUMPHREYS

A new x-ray spectrograph for wave-length determinations in air. S. ZEIDENFELD. *Rev. Sci. Instruments* **2**, 153–63(1931). E. H.

The accuracy of interference measurements in the molecule with Röntgen and cathode rays. L. BEWILOGUA. *Physik. Z.* **32**, 114–7(1931).—From a consideration of the theoretical "form factor" curves for Röntgen rays and for electrons, it is shown that, in general, the former must give more exact values for the distance between atoms in a single mol. T. H. CHILTON

Interferometer measurements in the infra-red region of xenon and iron. J. C. MCLENNAN AND FLORENCE M. QUINLAN. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 47–52 (1930).—An examn. of the infra-red region of the spectra of Xe and Fe was made to det. whether suitable lines might be found as secondary standards of wave length. Difficulty was found in reproducing the Xe spectrum because of a change of the pressure of the gas as the discharge tube became older. This makes the gas unsuitable as a source of accurate standard wave lengths. A table contg. the wave lengths of the arc spectrum of Fe from λ6677.994 to 8688.637 A. U. is given. J. W. SHIPLEY

Interpretation possibilities of the mercury hyperfine structures. H. SCHÜLER. *Naturwissenschaften* **18**, 895(1930).—The Hg lines, in general, appear to consist of one strong component and several weaker components so grouped that their center of gravity coincides roughly with that of the main one. The ratio of the intensity sum of the weaker components to the total intensity has been measured for Hg arc lines 4047, 4078, 4916, 5461, 5769, 5791 A. U. and for Hg spark lines 6150 and 7944 A. U. With 2 exceptions the ratio is between 0.25 and 0.32. According to Aston the odd-numbered isotopes constitute about 30% of the total so that the large hyperfine structure splitting of Hg lines may be ascribed principally to the odd-numbered isotopes, Hg_{199}, Hg_{201}. W. F. MEGGERS

Photoelectric intensity measurements in the mercury spectrum. II. L. S ORNSTEIN AND J. F. CUSTERS. *Proc. Acad. Sci. Amsterdam* **33**, 809–13(1930).—In the first paper (cf. *C. A.* **24**, 4458) it was stated that a characteristic relation of the line intensity I as a function of the current i exists at const. pressure, p, provided that the current is small and the pressure lies within a certain range. Further measurements show that I/i increases with decreasing i at all pressures, provided the current becomes sufficiently small. W. F. MEGGERS

Intensity measurements for the multiplet $z^5G - e^5F$. W. A. M. DEKKERS AND A. A KRUITHOF. *Z. Physik* **66**, 491–3(1930).—Intensity measurements of 9 lines in the Ni spectrum forming the multiplet $z^5G - e^5F$ (4592.532 to 4900.97 A. U.) were made under a variety of conditions; they confirm the deviations from the sum rule reported by Ornstein and Bouma (*C. A.* **24**, 5620). W. F. MEGGERS

Note on a phenomenon connected with the aurora. A. C. BURTON. *Can. J. Research* **4**, 52–3(1931).—A description with photographs is given of a brilliant white beam of light stretching across the sky from east to west on the night of Aug. 21, 1930. Microscopic examn. of the photograph showed a fine structure not observed visually. J. W. SHIPLEY

Excitation functions in the neon spectrum. W. HANLE. *Z. Physik* **65**, 512–6 (1930).—The intensities of various Ne lines as a function of the applied potentials which excite them are measured in the yellow and red, the potentials ranging from 20 to 100 v. Lines involving the same initial term are found to have the same excitation function. The marked dependence of intensity distribution in the spectrum upon gas pressure is ascribed to an effect of collisions. W. F. MEGGERS

Remark on our work "Intensity measurements in the copper arc." L. S. ORNSTEIN AND D. VERMEULEN. *Z. Physik* **66**, 490(1930).—In the work referred to (*C. A.* **25**, 249) the intensity ratio of the Cu doublet $1^2S - 2^2P$ was reported to deviate from the sum rule. Further measurements made with C electrodes contg. a trace of Cu so that the lines in question could be photographed with a long exposure led to the true value of the intensity ratio, *viz.*, 1:2. W. F. MEGGERS

Absorption spectra of dissolved mercury. H. REICHARDT AND K. F. BONHOEFFER. *Z. Elektrochem.* **36**, 753(1930).—The soly. of Hg in water at temps. below 130° is too small for the absorption spectrum of the metal to be detected, but at about 140° 2 absorption bands of about 20–30 A. U. width, due to the Hg atom, occur at 2600 and 2520 A. U. They are not derived by broadening and displacement of the normal lines

at 2650 and 2537 A. U., since in the solvents MeOH and C_6H_{12}, both of which contain dipoles, the bands occur at 2575 and 2530 A. U. and 2575 and 2545 A. U., resp.; they may result from division of the line at 2537 A. U. by the action of the elec. fields surrounding the solvent mols. B. C. A.

Interpretation of band spectra I, IIa, IIb. ROBERT S. MULLIKEN. *Rev. Modern Physics* **2**, 506–8(1930); cf. *C. A.* **24**, 2049. W. F. MEGGERS

Interpretation of band spectra. IIc. Empirical band types. ROBERT S. MULLIKEN. *Rev. Modern Physics* **3**, 89–155(1931). E. H.

Some bands of the carbon molecule. G. H. DIEKE AND W. LOCKTE-HOLTGREVEN. *Z. Physik* **62**, 767–94(1930).—Details are given for new bands resembling the Swan bands of C_2 (cf. *C. A.* **24**, 2050). W. F. MEGGERS

Radiation and characteristics of molecules. R. D. KLEEMAN. *Z. anorg. allgem. Chem.* **195**, 164–72(1931).—A general discussion. WILLIAM E. VAUGHAN

Structure and spectra of the molecules of hydrogen and helium. W. WEIZEL. *Z. Elektrochem.* **36**, 599–603(1930); cf. *C. A.* **24**, 3169.—A description is given of the manner whereby the band spectra of the H_2 and He_2 mols. may be developed by consideration of the arrangement of the electrons and protons, and the phys. significance and method of detg. the quantum nos. of the individual electrons are indicated. The origins of the ortho- and para-H spectra by sym. and asymmetric rotations are described. B. C. A.

Energy levels of molecular oxygen. J. C. MCLENNAN, H. D. SMITH AND J. O. WILHELM. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 65–79(1930).—The absorption spectrum of O_2 was studied in the gaseous, liquid and solid phases to det. the origin and relation of the bands observed in its spectrum. Particular attention was paid to the bands in the spectrum of liquid O_2. Wave-length tables and mol.-configuration diagrams are given. J. W. SHIPLEY

The band spectrum of silver hydride. ERNST BENGTSSON. *Nature* **127**, 14 (1931). –An improved source has greatly extended the range of the known spectrum. This source is an elec. arc operating in H at reduced pressure and having a pos. electrode made of a Ag-Al alloy. Greatly increased intensity has been attained as well as the elimination of the N_2 spectrum. The rotational structures of 14 bands belonging to the $^1\Sigma \longrightarrow {}^1\Sigma$ system have been analyzed and arranged in a vibrational scheme. The vibrational levels of the lower electronic state appear to be represented by the formula: $F''(v) = 1723.5v'' - 33.5v''^2 - 0.0094v''^3$. The excited electronic state shows irregularities of spacing in its rotational and vibrational levels which may be due to a perturbing electronic level. An approx. calcn. of the dissocn. energy in both states gives: $D' \sim 6300$ cm.$^{-1}$, $D'' \sim 19{,}000$ cm.$^{-1}$. The isotope effect is clearly shown with high dispersion. C. J. HUMPHREYS

Fluorescence of mercury vapor under atomic and molecular absorption. RAYLEIGH. *Nature* **127**, 10(1931).—The excitation of Hg vapor by radiation near the resonance line is due to both at. and mol. absorption. The at. absorption gives a type of fluorescence known as the core effect, since the radiation capable of this kind of absorption is limited to about 0.05 A. U. on either side of the resonance line. The intensity of this effect falls off very rapidly with penetration. The weaker fluorescence due to outlying radiation is called the wing effect, and is caused by mol. absorption. It is extinguished much less rapidly as the beam traverses the vessel. The reality of both effects has been confirmed by showing that a suitable addn. of H suppresses the core effect. C. J. HUMPHREYS

The vibrational levels of the iodine chloride molecule. W. E. CURTIS AND O. DARBYSHIRE. *Trans. Faraday Soc.* **27**, 77–87(1931); cf. *C. A.* **24**, 1026.—Const.-pressure measurements of the spectrum were made at 17° and 207° to compare the intensities. All of the vibrational progressions increased appreciably, invalidating the method for the detn. of vibrational levels. Some evidence indicated that the 2nd progression might remain const. and be identified with $v' = 1$. ARTHUR FLEISCHER

Raman effects with liquid and gaseous nitrous oxide. J. C. MCLENNAN, H. D. SMITH AND J. O. WILHELM. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 197–205(1930).—The Raman effect was studied for liquid N_2O as an example of a triat. mol. and the results were compared with those obtained by others. Tables and a discussion of the results are included. J. W. SHIPLEY

Infra-red spectroscopy. M. CZERNY. *Z. Elektrochem.* **36**, 615–8(1930).—A historical survey of the development of modern methods of infra-red spectroscopy, with some exptl. details. B. C. A.

Raman effect and its significance for the spectroscopic study of molecular structure. A. SMEKAL. *Z. Elektrochem.* **36**, 618–31(1930).—A survey of recent work. B. C. A.

Raman effect and chemical bonds in certain organic liquids. LESLIE E. HOWLETT. *Can. J. Research* **4**, 79–91(1931).—Spectrograms were taken of ethylene glycol and 5 of its derivs., 4 nitriles and benzyl alc. on a specially constructed spectrograph designed to study the Raman effect. By assuming the simple harmonic oscillator theory an attempt was made to assoc. certain frequencies with definite bonds and structures. The theory was applied through an expression derived for the frequencies characteristic of the elastically bound masses vibrating in a straight line. The value of the stretching force of all single bonds is assumed to be the same. Double and triple bonds are taken as having a stretching force 2 and 3 times, resp., that of the single bond. Frequencies in the neighborhood of 300 mm.$^{-1}$ are attributed to longitudinal vibrations between C and H. Lines near 160 mm.$^{-1}$ indicate a double-bonded C atom in the chain or ring. Lines near 225 mm.$^{-1}$ are due to the C≡N triple bond. Lines between 50 mm.$^{-1}$ and 150 mm.$^{-1}$ are due to the longitudinal vibrating chain. Frequencies less than 50 mm.$^{-1}$ are probably due to transverse vibrations of the chain, while some lines near 140 mm.$^{-1}$ may be due to transverse vibrations of H. In the ethylene glycol compds. lines near 86 mm.$^{-1}$ are assigned to the presence of O at the end of the chain. Lines near 72 mm.$^{-1}$ and 65 mm.$^{-1}$ are attributed to the longitudinal vibrations of Cl and lines near 42 mm.$^{-1}$ and 30 mm.$^{-1}$ are attributed to transverse vibrations of Cl. J. W. SHIPLEY

The influence of absorption of light on the rate of photochemical reactions. A. K. BHATTACHARYA AND N. R. DHAR. *Z. anorg. allgem. Chem.* **196**, 26–32(1931); cf. *C. A* **24**, 553.—The relationship between absorption of light and reaction rate was obtained for the following photochem. reactions: $K_2C_2O_4$ with I, $FeSO_4$ with I and citric acid with H_2CrO_4. The exponent in the equation relating absorption of radiation to reaction rate can vary from a proper fraction to 2, it is independent of the relationship between the light and dark reaction. Tabulated data are given. E. J. ROSENBAUM

Photochemical dissociation of triatomic molecules. II. Potassium cyanide. DONALD S. VILLARS. *J. Am. Chem. Soc.* **53**, 405–11(1931); cf. *C. A.* **24**, 1034.—KCN vapor at 875° was found to absorb in 2 regions, the long wave-length limits of which are approx. 2175 (5.7 v.) and 2900 (4.3 v.) A. U. The former region is interpreted as corresponding to the dissocn. into a normal atom and an excited one (K excitation 1.6 v.; CN excitation, 1.8 v.); the latter corresponds to dissocn. into 2 normal atoms or radicals. This agrees with theoretical considerations. WILLIAM E. VAUGHAN

Photochemical studies. XII. Photochemical reaction between nitric oxide and mercury vapor. W. ALBERT NOYES, JR. *J. Am. Chem. Soc.* **53**, 514–26(1931).—The reaction between NO and Hg in the full radiation of a quartz-Hg lamp immersed in water has been studied from pressure decrease in the system. The reaction seems to lead to the formation of NO_2, which may react with Hg to give N_2. Both quartz and Corex glass cells were used; the pressure of the NO was initially approx. 0.1 mm. The rate in all cases was computable on the basis of a monomol. reaction rate equation. Initial pressures were varied over the range 0.1128 to 0.00338 mm. and the monomol. rate still applied. The value of k_1 decreases with high pressures of the order of 24 mm Removal of Hg vapor practically stopped the reaction. Some studies on the quenching of the fluorescence of Hg by NO were made; 72% quenching at 2 mm. and 85% at 6 mm. A detailed theoretical discussion is given; various mechanisms are discussed. It is thought that a NO mol. in a high vibration state of the normal electron level is produced by collisions of the 2nd kind. WILLIAM E. VAUGHAN

The photosensitized decomposition of nitrogen trichloride and the induction period of the hydrogen-chlorine reaction. J. G. A. GRIFFITHS AND R. G. W. NORRISH. *Nature* **127**, 14(1931).—The inhibiting effect of the addn. of small measured quantities of NH_3 on the induction period of the photochem. H-Cl reaction is due to the formation of NCl_3, which undergoes photosensitized decompn. in the presence of excess Cl. Quantum-efficiency measurements indicate that the decompn. of NCl_3 proceeds by way of reaction chains of short length, the quantum efficiency falling to a lower limiting value of about 2 as the Cl pressure is increased. Gases such as He, A, N and O, when added to mixts. of NCl_3 and Cl_2, have sp. retarding effects on the decompn.; and, as the pressures are increased, depress the quantum efficiency toward the above limiting value. C. J. HUMPHREYS

The absorption of aqueous tartaric acid solutions. RENE LUCAS AND MARCEL SCHWOB. *Compt. rend.* **192**, 225–7(1931).—The relative results of ultra-violet absorbing powers of aq. tartaric acid solns. were detd. with the help of photoelec. cells, the photoelec. cell arrangement of Halban and Siedentopf (*C. A.* **16**, 2078) being used. Contrary to previous observations, Beer's law was not verified. The variations are

particularly marked for 2536 A. U., the sp. absorption varying more than 200%. Dil. solns. having greater absorbing power than concd. solns. M. McMAHON

Absorption spectrum of lignin derivatives in the ultra-violet. ERIK HÄGGLUND AND F. W. KLINGSTEDT. *Z. physik. Chem.*, Abt. A, **152**, 295–312(1931); cf. *C. A.* **24**, 1578.—The absorption spectra of the alkyllignins, the ligninsulfonic acids and the alkali lignins have been measured by the method of Victor Henri by means of the small Hilger quartz spectrograph. The general similarity of the spectra of the different substances points to the fact that they have a common residue; there is, however, a distinct difference between the spectra of derivs. of lignin from conifers and from deciduous trees. Selective absorption is relatively strong, which indicates the existence of at least 1 aromatic ring in the fundamental substance of lignin. W. WEST

Potassium chromate and potassium dichromate as light filters and the constitution of chromic acid from absorption measurements. W. V. BHAGWAT AND N. R. DHAR. *J. Indian Chem. Soc.* **7**, 913–21(1930).—Detn. of extinction coeffs. shows that: wave lengths shorter than 5150, 4950, 4950, 4600, 4300 and 4000 A. U. are completely absorbed by 1 cm. of 5.5 (satd.), 2, 1, 0.1, 0.01, and 0.001 *N* K_2CrO_4 solns., resp.; wave lengths shorter than 5600, 5200, 4600 and 4000 A. U. are completely absorbed by 1 cm. of 1.17 (satd.), 0.1, 0.01 and 0.001 *N* $K_2Cr_2O_7$ solns., resp. The % transmission in the range 5600–6700 A. U. is greater with satd. K_2CrO_4 than with satd. $K_2Cr_2O_7$ soln. In 0.001 *N* solns. K_2CrO_4 transmits light of wave lengths 5400–6700 A. U. better than K_2CrO_4. Neither K_2CrO_4 nor $K_2Cr_2O_7$ solns. obey Beer's law. In dil. solns. the absorption-concn. curves for K_2CrO_4 and $K_2Cr_2O_7$ are strikingly similar. Although concd. solns. of dichromate contain $Cr_2O_7^{--}$ and $HCr_2O_7^-$ ions, the dil. solns. contain mainly CrO_4^{--} and $HCrO_4^-$ ions. OSCAR T. QUIMBY

The law of paramagnetic rotation of xenotime and its experimental verification. JEAN BECQUEREL, W. J. DE HAAS AND H. A. KRAMERS. *Compt. rend.* **191**, 839–41 (1930); cf. *C. A.* **24**, 2047. GERALD M. PETTY

Quantum theory of chemical kinetics. Unimolecular reactions. S. ROGINSKII AND L. ROSENKEVICH. *Z. physik. Chem.*, Abt. B, **10**, 47–85(1930).—A unimol. decompn. or rearrangement can be viewed either as originating in an internal force field within the complicated mol., which causes the expulsion of a part of the mol. in a manner analogous to the mechanism of γ-ray disintegration as pictured by Gramow and by Gurney and Condon, or as a rearrangement of its parts whereby new chem. linkages are formed and simultaneously a part of the old linkages is disrupted with the consequent emission of part of the original mol. This latter process has its analog in the Auger effect, as *e. g.*, in the excitation and simultaneous spontaneous ionization of a He atom. Both schemes lead to the correct expontential form of relation between velocity const. and temp.; but it is argued that there is no exptl. evidence for the kind of interaction between the mol. and the emitted particle necessary in the first scheme. The Auger process gives $k = e^{-A/kT} \cdot e^{\beta(Q-A)/\sqrt{A}}$, where A is the energy of activation, Q the heat of the reaction, and β a factor depending only slightly on the nature of the mol. This requires an exponential relation between the consts. A and B of the Arrhenius equation $k = Be^{A/kT}$, which is shown to be experimentally satisfied. The order of a reaction is detd. by the relative values of Q and A; the conclusions are applied to known cases and used in predictions concerning reactions for which data are still wanting. W. WEST

Chemical combination and the line emission of solid bodies. R. TOMASCHEK. *Z. Elektrochem.* **36**, 737–43(1930).—A survey of work on the spectrum of Sm in phosphors. Cf. *C. A.* **18**, 3546; **19**, 935; **22**, 915. B. C. A.

The ionization of air during the oxidation of phosphorus. J. TAUSZ AND H. GÖRLACHER. *Physik. Z.* **32**, 91–7(1931).—Ionization measurements were carried out incidental to work on the oxidation of P in air and O_2, both pure and in the presence of poisons for the reaction (*C. A.* **24**, 4476). When P was oxidized by air, the ionization increased with air velocity, temp., and P surface. Pure O_2, when wet, showed no increase in ionization over air, but showed a progressive increase during drying. Strongly poisoning substances such as isoprene and cyclohexane mixed in air caused considerable decreases in ionization depending on the concn. T. H. CHILTON

4—ELECTROCHEMISTRY

COLIN G. FINK

Recent progress in the use of the electric furnace in the steel industry. ALBERT LEVASSEUR. *Arts & métiers* **1931**, 54–60; cf. *C. A.* **24**, 5236.—An address. A. P.-C.

A modern electric steel plant. K. VON KERPELY. *Giesserei-Ztg.* **27**, 101–2(1930).—A description of the new elec. steel plant (wire, cable, etc.), at Campia Turzii, Roumania. CURTIS L. WILSON

Artificial atmospheres for electric furnaces and their application. A. N. OTIS. *Iron Age* **126**, 767–70, 844–8(1930).—Results of Cu-brazing of steel parts, of annealing sheet steel, strip and lamination punchings for elec. generators and transformers indicate that there is a wider field of application. A simple app. has been developed for producing, from readily available materials, suitable gases rich in H at a fraction of the cost of H_2 produced by the usual methods. N may be used as a diluent of H. Where there is a demand for atomic H for welding, NH_3 may be dissociated by heat into a gas consisting of 75% H and 25% N. The production of *electrolene* is described. The H content prevents oxidation and the small CH_4 content prevents decarburization. The content of the gas is controlled by the operating temp. of the dissociator. Several diagrams, tables and illustrations of different types of furnaces are included. W. H. BOYNTON

Production of alloy steels in coreless induction furnaces. O. DÖRRENBERG AND N. BROGLIO. *Stahl u. Eisen* **50**, 617–26(1930).—After a review of the development of the high-frequency induction furnace and a discussion of the elec. principles on which it is constructed, an account is given of the installation and performance of one of these furnaces in a German steelworks. The transformer efficiency is about 78–80%, and the current consumption for a 300-kg. charge starting in the cold is 600 kw. hr./ton to effect complete fusion and 730–790 kw. hr./ton until casting is complete; the av duration of melting is 90–100 min. Curves showing the elec. conditions during the melting of several charges are given, and the operation of the furnace is compared with that of a gas-fired crucible furnace. B. C. A.

Tonnage melting by coreless induction. E. F. NORTHRUP. *Iron Age* **127**, 228–33 (1931).—The first of a series of articles on the theory, operation and uses of the high-frequency induction furnaces. For power requirements of 50 kw. or less, the Hg gap type of oscillator is best in present practice. For greater power, the motor or turbine driven generator giving frequency well within design and economic limits will best meet requirements. Mechanically considered, the steel housing is lined everywhere on its inner surface with high-cond. sheet Cu about 1/4 in. thick. This lining prevents eddy currents from being induced in the steel housing. The best results are obtained when using a "graded" coil without vacant spaces between turns. G. T. M.

Valve-operated coreless induction furnace for high-temperature research. FRANK ADCOCK. *Trans. Faraday Soc.* **26**, 544–60(1930).—A detailed description of the app. and circuit used is given, particular attention being paid to special features in design, safety appliances and the application of the furnace to metallurgical researches at high temps. Two air-cooled silica valves, each capable of dissipating 2.5–3.0 kw. at the anode, are employed on the "push-pull" or "back-to-back" principle. The valve filaments are rated at 40 amps. and 17.2 v. and are supplied with a. c. by means of a transformer with a center-tapped secondary. A combination of grid leak and condenser in conjunction with an accumulator bank maintaining a neg. potential of 36 v. is used to apply the correct grid bias to the oscillating valves. Accurate regulation of the power supply is obtained by means of a condenser potential divider by means of which a definite fraction of the full oscillatory voltage in the furnace circuit is rectified and passed through a milliammeter used as an indicator. Frequencies of 50,000 and 1,000,000 cycles per sec. are used, special furnace construction (from the viewpoint of insulation between the turns of the inductor coil) being devised for the higher frequency. Owing to the high frequencies employed the furnace is capable of heating efficiently

charges consisting of small metallic fragments. "Bridging" (*i. e.*, the formation of a liquid pool by the lower portion of the charge while the upper portion remains as a relatively cool "bridge") of the charge on melting is not very pronounced at the 1 million cycles per sec. frequency. Detailed descriptions (with drawings and photographs) of the component parts of the furnace set-up are given. Observations on technic and applications of the furnace to the obtaining of high-temp. thermal curves, and to magnetic and resistivity investigations are also included. EDWARD B. SANIGAR

Refining of ferrochrôme in coreless induction furnaces. C. TAMA. *Arch. Eisenhüttenw.* **4**, 55–61(1930).—Production of Fe-Cr, decarbonization in coreless induction furnaces, suitable refractories for lining, and refining are considered. The systems Fe–Cr, Fe–Cr–C, and Cr–C are discussed in the light of the recent investigations. A charge of 300 kg. of Fe–Cr is usually melted in 70–100 min. in a 50-cycle furnace or in 60–80 min. in a 500-cycle furnace, and a charge of 30 kg. takes only 40 min. in a 10,000-cycle furnace. The power consumed varies from 750 to 1850 kw. according to the type of the furnace. G. T. MOTOK

Chromium-plating of paper-mill rolls. R. E. CLEVELAND. *Paper Mill* **54**, No. 4, 14-5(1931).—A brief discussion of the advantages of Cr-plating paper-mill rolls to increase their life by its hardness and resistance to corrosion. A. PAPINEAU-COUTURE

Cathodic protection of metals in neutral solutions. U. R. EVANS. *Metals and Alloys* **2**, 62–4(1931).—A table gives values for c. d. below which production fails for several steels and irons. A. J. MONACK

Buffer action in nickel-plating solutions. K. PITSCHNER. *Metal Ind.* (N. Y.) **29**, 119–20(1931).—The resistance to change in p_H exhibited by a soln. when it is subjected to gain or loss of acid or alkali varies greatly at different p_H values. Certain reagents, which are now common constituents in Ni-plating solns., have the property of depressing the tendency toward large changes in p_H. The buffer effects of boric acid and of NH_4Cl on Ni content were studied. The extent of buffer action is evaluated by the Van Slyke method. It is the differential ratio of the increment in g. equivs. of strong acid or base added per l. of the soln. to the resultant increment or change of p_H. The buffer effect is highest at the upper end of the p_H range and least in the vicinity of p_H 4.0 only 1/20–1/100 of the value at p_H 6. In the usual plating range of p_H 6–5, the buffer effect is more noticeable when alkali is added, while in the range around p_H 2.5, the reverse is the case. The NH_4Cl content of Ni solns. is kept high enough so that the anode corrosion will keep the trend of p_H toward the upper limit of the range. Addns. of acid only are necessary. A brief discussion is included. Exptl. results are tabulated. W. H. BOYNTON

Studies in the electrodeposition of nickel. II. The effect of current density and temperature. J. B. O'SULLIVAN. *Trans. Faraday Soc.* **26**, 533–9(1930); cf. *C. A.* **24**, 1801.—The influence of cathode c. d. and temp. on the appearance, structure and deposition potential of Ni deposited from buffered $NiSO_4$ solns. having various p_H values has been studied. The solns. used and the prepn. of the deposits were as reported in Part I of this work (*C. A.* **24**, 1801). Deposits were obtained at 17° and 35° at c. ds. of 2, 5, 10 and 15 ma./sq. cm. Deposition potentials were measured against a satd. calomel half-cell, a capillary electrode tip in contact with the cathode surface being used. Tables showing the appearance of the deposits and tables of deposition potentials are given, as well as graphs of the deposition potentials against the logs of the c. ds. (giving straight lines). Tables of the deposition potentials at unit c. d. (obtained by extrapolation of the above graphs) and of the slopes of the above graphs are also given. The varied surface structure of the Ni deposits is explained as due to variations in the throwing power (mainly dependent on the slope of the deposition potential-c. d. curve) of the solns. The slope of the deposition potential-log c. d. curve and the deposition potential at unit c. d. were found to vary from one soln. to another. From this it is deduced that the constants of the Freundlich adsorption isotherm are functions of the p_H of the soln. and of the nature of the buffering agent employed. **III. Effect of small quantities of iron and aluminum.** *Ibid* 540–3.—In Part I of this work it was shown that the structure of a Ni deposit varies according to the p_H of the plating bath and the nature of the buffering agent employed, and it was suggested that this was due to the formation of some colloidal $Ni(OH)_2$ or basic salt in the cathode film and its co-pptn. with the metallic Ni. The investigation has been extended by examg. the effect of adding to the plating bath small quantities of inorg. salts which would be likely to yield colloidal hydroxides at a lower p_H than is required for $Ni(OH)_2$, *i. e.*, at a p_H where $Ni(OH)_2$ would be exerting little influence. Fe (added as $FeSO_4$ or $FeCl_3$ soln.) and Al (as potash alum) were used for this purpose. Expts. were performed with solns. contg. 24 g. $NiSO_4.7H_2O$ and 1.56 g. NaCl per 100 cc., with a Fe ',

Fe$^{\cdots}$ or Al to Ni ratio of 1:1000 or 1:200 at p_H's from 3.9 to 4.7, deposition being continued for 30 min. at a c. d. of 10 ma./sq. cm. It was found that small amts. of Fe salts had no appreciable effect on the electrodeposition of Ni, and it is suggested that this is due to the preferential deposition of Fe, whereby this metal is removed from the cathode film before it can form any colloidal compds. Al can accumulate in the cathode film until colloidal compds. are formed, and if this process proceeds far enough the structure of the deposit is altered; it becomes black or "burnt." The black deposits were found to contain appreciable amts. of Al (0.0006 g. in 0.65 g. deposit) whereas none could be detected in the white deposits (which were somewhat finer-grained than those from solns. contg. no Al) so that it is suggested that the change is due to the co-pptn. of colloidal $Al(OH)_3$ with the Ni. A discussion is given of the possible ways in which colloidal hydroxide—either as a film at the cathode or, with an amphoteric colloid, as a film some little distance from the cathode—could cause finer-grained deposits. EDWARD B. SANIGAR

Electrodeposition of zinc on aluminum from sulfate solutions. H. C. COCKS. *Trans. Faraday Soc.* **26**, 517–26(1930); cf. *C. A.* **24**, 2058.—Measurements were made of the deposition potential of Zn from *N* $ZnSO_4$ solns. with first c. d. and secondly p_H of the soln. as the only variable. Some static potentials were also detd. and observations made upon character of deposits, gas evolution and adhesion of bubbles. Expts. were done with buffered and with unbuffered solns. at c. ds. of 4.5, 9, 18 and 36 amp./sq. ft. at a temp. of 20°. Com. Al sheet (contg. 0.14% Si and 0.58% Fe), prepd. by sandblasting at 5–10 lb. pressure, was used as cathode. Potentials were measured by the capillary tip method. Tables are given for both buffered and unbuffered solns. showing the effect on the deposition potential and on the deposits, of various addition agents and of p_H. Graphs of the cathode potential against c. d. are also given. The potential measurements indicate that the addn. agents should increase the throwing power of an unbuffered $ZnSO_4$ soln. somewhat when its p_H is 3–4. The order of merit of the addn. agents in giving smooth, fine-grained deposits was found to be gum arabic plus β-naphthol, gum arabic, β-naphthol, glucose, while a parallelism was found between the order of efficiency of the addn. agents in improving the deposits, increasing the change of deposition potential with c. d. and increasing the actual value of the polarization. The static potentials of Zn deposits and of sandblasted Zn sheet in both buffered and unbuffered solns. were found to vary with time and with p_H. For a given soln. the deposition potential became more neg. with decrease of p_H at a fixed c. d., and more neg. with an increase of c. d. at a fixed p_H. These changes were barely detectable in the absence of addn. agents. Suggestions are given to explain these results. The deposits from the buffered and the unbuffered solns. were mostly dull white. The deposits improved with decrease of p_H and increase of c. d. The addn. agents had marked effects on the deposits. Change of p_H had a less marked effect on deposits from buffered than on those from unbuffered solns. Gas pits on the deposits usually increased with decrease of p_H and increase of c. d. From agitated solns. there were generally no gas pits from solns. of p_H 6 and only rarely from solns. of p_H 5. A comparison of the p_H values of the solns. employed obtained by the quinhydrone and by the colorimetric methods is given. Within the range of p_H 3.0–6.0 the quinhydrone values were the lower (extreme deviations, 0.2 and 0.8 p_H). A soln. contg. *N* $ZnSO_4$, 0.25 *N* NaOAc and 1 g./l. of gum arabic, with or without 0.1 g./l. of β-naphthol, is suggested as likely to prove most suitable for Zn deposition on Al and its alloys. E. B. S.

Electrolytic zinc. CHARLES W. CUNO. *Chem. Markets* **28**, 253–6(1931).—The advantages of the electrolytic over the smelter process are described. E. H.

Adhesion of electroplated coatings. W. BLUM. *Metals and Alloys* **2**, 57–9(1931).—A review. A. J. MONACK

Electrodeposition of platinum, palladium and rhodium. W. KEITEL AND H. E. ZSCHIEGNER. *Trans. Electrochem. Soc.* 59 (preprint) 4 pp.(1931).—The chloride plating bath for Pt metals is not satisfactory because of its short life. A new bath was accordingly developed in which the Pt is present as the diamminonitrite. Good, bright adherent deposits are obtained. The throwing power is very good. A similar bath for Pd was likewise developed and has given very satisfactory results. C. G. F.

The limiting current density in the electrodeposition of noble metals. S. GLASSTONE. *Trans. Electrochem. Soc.* 59 (preprint) 8 pp.(1931).—The literature of electrochemistry does not appear to contain a simple equation permitting the calcn. of the max., or limiting, c. d. at which a metal can be deposited with 100% current efficiency. Such an equation is now developed on the assumption that the max. rate of deposition is equal to the max. rate at which the ions contg. the metal to be deposited can diffuse up to the cathode. The values calcd. in this manner are shown to be in good agreement

with those observed, although discrepancies may arise when there is a possibility of H_2 evolution. C. G. F.

Isothermal metallic cells. O. SCARPA. *Mem. accad. Italia, Classe sci. fis. mat. e nat.* **1**, *Chim.* No. 5, 28 pages(1930).—This study deals with the degree of freedom of ions in solid and liquid metals. The motion of ions in metals diffusion in solid metals, also the e. m. f. of contact of metals and thermodynamical calcn. are considered in the first part of the paper. This cell may consist of the following:

Cu	Hg	Zn	Cu
Cu	Hg	Cd	Cu
Cu	Hg	Zn amalgam	Cu
Cu	Hg	Cd amalgam	Cu

With Zn amalgam a satn. point of 0.75×10^{-6} v. is reached at 19° with a concn. of 5.5 atomic per cent of Zn. G. T. MOTOK

Theory of electrolytic diaphragm cell. FRANCESCO GIORDANI. *Mem. accad. Italia Classe sci. fis. mat. e nat.* **1**, *Chim.* No. 6, 75 pages(1930).—A mathematical study of electrolysis based on the expts. carried out in a new type of electrolytic diaphragm cell for the production of caustic alkalies (developed by Giordani and Pomilio). This cell is set vertically with the graphite electrode in the center and the diaphragms on both sides of the electrode. The formula for instantaneous discharge in the electrolytic diaphragm cell can be written: (*A*) $R = 1 - \{n/[1 + (x_1/x_2)]\}$ and the ratio x_1/x_2 can be expressed as a function of the concn. C_1 and C_2 of the chloride and the hydroxide dissociated at the cathode: (*B*) $x_1/x_2 = Am(C_1/C_2)$ and (*C*) $C_1 = C_o - BC_2$. *A* and *B* are functions of the initial concn. C_o and temp. By substituting (*B*) and (*C*) in (*A*), there is obtained (*D*) $R = (1 + MC_2)/(1 + NC_2)$, where *M* and *N* are also functions of C_o and temp. For higher values *M* is eliminated and (*E*) $R = 1/(1 + NC_2)$ results, the formula which was obtained by Guye. G. T. MOTOK

The electrochemical oxidation of ketones. I. A preliminary paper. W. E. BRADT AND CARL J. OPP. *Trans. Electrochem. Soc.* **59** (preprint) 8 pp.(1931).—Acetone was oxidized at a Pt wire gauze anode at low anodic c. ds. The course of the oxidation was followed by the collection and the analysis of consecutive portions of the gaseous oxidation products. The effect of variation of the c. d. on the compn. of the anode gas was investigated. The anode gas from the oxidation of acetone normally contained CO_2, CO, O_2, unsatd. hydrocarbons, CH_4 and C_2H_6. Analyses of the anode soln were made. In every case, aldehydes, MeOH and pyruvic acid were absent. The anode soln. normally contained formic acid, acetic acid, *mesityl oxide*, unchanged acetone and a tar. At higher c. ds. phorone was identified. Efforts were made to show the disposition of all the acetone originally placed in the cell. C. G. F.

The alleged electrochemical sulfonation of an aromatic hydrocarbon. FR. FICHTER, H. E. SUENDERHAUF AND A. GOLDACH. *Helv. Chim. Acta.* **14**, 249–53(1931).—An emulsion of PhMe, EtOH and concd. H_2SO_4 was electrolyzed with an anode c. d. of 0.19 amp./cm.^{2} The acidic portion of the product was converted into Ba salts. $Ba(OAc)_2$ and $(EtOSO_3)_2Ba.2H_2O$ (I) were the only products isolated. No $C_6H_4(SO_3Ba)CO_2$ was found, contrary to reports in the literature (Puls, *Chem.-Ztg.* **25**, 263(1901)). The electrolysis of a mixt. of EtOH and H_2SO_4 yielded the same products free from resins produced by the oxidation of the PhMe. On the other hand, a like operation on PhMe and H_2SO_4 yielded no acid. **The electrochem. oxidation of acetophenone.** H. E. SUENDERHAUF. *Ibid* **14**, 253.—The electrolysis of PhAc emulsified with H_2SO_4 led to the formation of small yields of *maleic* and *fumaric acids*. Some phenolic compds. were also present among the products. I. M. LEVINE

Electrolytic reduction of 4-keto-3-phenyl-3,4-dihydroquinazoline. H. ITOML. *Mem. Coll. Sci. Kyoto Imp. Univ.* **13A**, 311–3(1930).—Electrolytic reduction of 4-keto-3-phenyl-3,4-dihydroquinazoline with a lead cathode and aq.-alc. Na_2CO_3 as the cathode soln. at 25° gives *4-hydroxy-3-phenyl-1,2,3,4-tetrahydroquinazoline*, m. 170–1°, in 40% of the theoretical yield. Both the above quinazolines are reduced to *3-phenyl-1,2,3,4-tetrahydroquinazoline*, m. 118–9°, when the cathode consists of Cu coated with Pt black and reduction is carried out at 50–60°. B. C. A.

Electrolytic Peltier heats and their measurement by isothermal, adiabatic, differential calorimetry. E. LANGE AND J. MONHEIM. *Z. physik. Chem.*, Abt. A, **150**, 177–202 (1930).—The electrolytic Peltier heats at reversible electrodes are discussed in relation to other thermodynamical quantities characteristic of the electrolytic cell. Earlier measurements are reviewed, and an isothermal, adiabatic, differential calorimetric method is described and has been applied to the Hg | Hg_2^{++} electrode, using a Hg elec-

trode in $HgNO_3$ soln. and the normal HgCl electrode. The tabulated values show an increase in the pos. direction with increasing metal-ion concn., in agreement with theoretical prediction. B. C. A.

Method of mapping equipotential lines and its application to electrical precipitator problems. A. W. SIMON AND L. C. KRON. *Rev. Sci. Instruments* **1**, 527–36(1930). B. C. A.

Construction, operation and characteristics of photoelectric tubes. LEWIS R. KOLLER. *J. West Soc. Eng.* **36**, 15–25(1931).—A discussion of the characteristics of the different types of photoelec. tubes showing what kind of tubes should be collected, with their operating limits for the different services. Metals of the alkali group are used in these tubes. Compds. of these metals change the sensitivities markedly. One of the most useful characteristics of the photoelec. cells is the relation between current and illumination. This is strictly linear over a wide range. The photoelec. tube is sometimes called the "electric eye." Alone it is less sensitive than the human eye, but with the aid of an amplifier it is 20 times as sensitive. Several types of amplifier are discussed. Where a great constancy in operation is required, vacuum tubes should be used. Outstanding applications of the tubes are: television, talking pictures, smoke detectors, counters, bean sorters, light recorders, color analyzers, phys. photometers and innumerable control devices. W. H. BOYNTON

Hydrogen-cooling for turbine-generators. M. D. ROSS. *Elec. Eng.* **50**, 211–4 (1931).—Actual operating experiences with a 7500-kv.-amp. unit are outlined. Five advantages of H_2 as a cooling medium for rotating elec. machinery are: (1) Windage losses are reduced to about 18% of their value in air. (2) For a given amt. of active material the rating of a generator with H_2 cooling is 25% greater. (3) Corona has little effect on insulation in H_2 atm., increasing the life of the insulation. (4) Fires in the generator are impossible, on account of absence of O_2. (5) Smaller gas coolers and less cooling water are required than with air cooling. W. H. BOYNTON

The relative merits of gas, oil and electricity for industrial purposes (HOPKINSON) **13**. Special refractories for electric-furnace linings (KUKLA) **19**. Some new facts of a chemical nature in the field of corrosion investigations and in the protection of metallurgical products against corrosion (COURNOT) **9**. Corrosion of steel water pipes by stray electric currents (ROTHE) **9**. Electrochemical oxidation of paraffin (ATANASIU) **22**. Au and Ag solutions (Brit. pat. 338,383) **18**. Heat treatment of loaded electrical conductors (Brit. pat. 338,169) **9**. Rubber battery boxes (Brit. pat. 338,114) **30**.

BILLITER, JEAN: **Électrométallurgie des solutions aqueuses.** Translated from 2nd German ed. by J. Salauze and S. Salauze. Paris: Dunod. 324 pp. F. 84.

Dry batteries. SOC. ANON. LE CARBONE. Ger. 514,966, Feb. 16, 1924. The Zn and C electrodes are embedded in an electrolyte mixed with pectinizable colloid and powd. C. The example mentions a mixt. of NH_4Cl, arrowroot starch and powd. wood charcoal.

Dry cell electric battery. H. A. BUMKE GES. Brit. 337,869, Aug. 27, 1929. Mech. features.

Storage battery. SOC. ANON. DES ACCUMULATEURS MONOPLAQUE. Brit. 337,375, Feb. 5, 1929. Between each pair of neg. plates there are placed two pos. plates each having half the thickness of the neg. plates, the pos. plates being joined together and enclosing electrolyte which tends to remain at max. concn. The electrolyte passes through the pos. plates under the influence of hydrostatic and electro-osmotic pressures. Alternatively, a single hollow pos. plate contg. an inert packing may be used

Galvanic batteries. KARL KUPKA. Ger. 514,967, May 23, 1928. Details of arrangement of the electrodes in multicell batteries are given.

Selenium cells. FIRMA CARL ZEISS. Ger. 514,911, Jan. 8, 1929. Se cells contg. two Pt electrodes mounted on glass or quartz and a channel contg. Se are described

Selenium cell of the condenser type. "SELENOPHON" LICHT- UND TONBILDGESELLSCHAFT M. B. H. Ger. 514,972, Feb. 4, 1930. Details of arrangements are given.

Light-sensitive selenium cells. TELEFUNKEN GES. FÜR DRAHTLOSE TELEGRAPHIE Brit. 337,691, Feb. 13, 1929. A cell formed on polished glass comprises electrodes formed by graphite deposited from a colloidal suspension on portions previously etched the suspending medium being driven off by heating and the interstices coated with Se or Se and Te together.

Electrodeposition of metals on rotating cathodes. S. O. COWPER-COLES. Brit.

338,173, May 16, 1929. In the deposition of metals such as Cu, Zn, Ni or Ag, a slowly rotating cathode is used which is supported on rollers above an arc-shaped anode and driven by rollers. The anodes may either be formed of the metal to be deposited or of inert material such as Pb, C or ferro-Si and the electrolyte may contain the compd. of the metal to be deposited either in soln. or in suspension. Deposition may be effected directly from ore. App. is described.

Forming acoustic diaphragms of thin metal such as nickel by electrodeposition. ALBERTIS HEWITT (to Victor Talking Machine Co.). U. S. 1,793,483, Feb. 24. Various details of app. and procedure are described.

Nickel-coated articles. FRANK V. KNAUSS (to Madsenell Corp.). U. S. 1,793,936, Feb. 24. A Ni-surfaced article such as a spring steel bar is treated as anode in a H_2SO_4 bath and a fresh Ni coating is then electrodeposited on the treated Ni surface. A firmly adherent coating is formed which takes a good polish.

Electroplating ferrous metal articles with zinc. SIDNEY H. DAVIS, CARL O. ANDERSON, RUDOLPH J. STENGL, WM. N. SMITH and HERBERT R. HANLEY (to Century Zinc Co.). U. S. 1,795,081, March 3. Articles are first provided with a thin coating of Zn by electrodeposition from a $ZnSO_4$ soln. of suitable acidity with a current of suitable d.; the articles are then transferred to a second bath of $ZnSO_4$ soln. of relatively higher acidity and the plating is continued with a current of higher d.; and the c. d. is finally lowered and the plating further continued to produce a coating of the desired thickness.

Electroplating zinc on iron or steel. SIDNEY H. DAVIS, CARL O. ANDERSON, WM. N. SMITH and HERBERT R. HANLEY (to Century Zinc Co.). U. S. 1,795,079, March 3. A thin initial coating is formed on an article by current from an insol. anode in a bath comprising a $ZnSO_4$ soln. of relatively low acidity by using a d. c. of relatively high c. d., and further plating is effected with a current of lower d. in a bath of higher acidity with further use of an insol. anode. U. S. 1,795,080 relates to plating with Zn after preliminary deposit of a thin coating of spongy Pb from an alk. Pb-bearing soln. by current of low d. from an insol. anode and brushing to remove some of the Pb and cause penetration of the ferrous metal by the remaining Pb.

Electroplating apparatus suitable for continuous operation. CHRISTIAN H. JORDING (to John W. Brown Mfg. Co.). U. S. 1,793,551, Feb. 24. Structural features.

Anode container for electroplating apparatus. THOMAS G. MELISH. U. S. 1,792,998, Feb. 17. Structural features.

Apparatus for electroplating successive portions of a large area such as the interior of oil stills, etc. KEVIE W. SCHWARTZ (to United Chromium, Inc.). U. S. 1,794,487, March 3. Various structural details are described including means for moving the anode to different positions for use.

Apparatus for electroplating articles such as in the manufacture of "copper-clad" roofing. CHARLES E. YATES (to Anaconda Sales Co.). U. S. 1,794,748, March 3. Structural features.

Plating interior surfaces of metallic vessels. EDWARD O. DUNKLEY (to Standard Oil Co. of Calif.). U. S. 1,793,069, Feb. 17. Various details of app. and procedure are described for operations such as plating the interior of large metal vessels with Cr.

Continuous process for chromium-plating metal wires or strips. BYRON V. MCBRIDE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,794,973, March 3. The wire or strip is drawn downward through a Cr-plating soln. in such a manner that all portions are substantially equidistant from the anode and exposed directly to the voltaic action of the bath, and then drawn upward through the soln. in such a manner that all portions are again substantially equidistant from the anode and exposed directly to the voltaic action of the bath. App. is described.

Selectively chromium-plating portions of surfaces such as those of reflectors. VICTOR L. SODERBERG. U. S. 1,794,929, March 3. Portions of the surface which are to remain unplated are covered with nitrocellulose lacquer preliminarily to the plating operation.

Electrolytic cell. I. G. FARBENIND. A.-G. (Georg Pfleiderer, inventor). Ger. 514,741, Nov. 2, 1926. Addn. to 471,925 (*C. A.* **23**, 2376). In a bipolar cell, especially for the decompn. of water (as described in 471,925), a portion of the electrolyte is passed continuously through an outside circulatory system to regulate the temp. and concn. The app. is described.

Electrolytic cell. SOCIÉTÉ D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIMIQUES. Ger. 514,501, Oct. 25, 1928. The cell has a middle partition and porous containers between the partition and the electrodes, the containers being raised from the bottom of the cell to permit free flow of the electrolyte.

Construction for maintaining a constant electrolyte level in electrolytic cells. CARL ROTH (to I. G. Farbenind. A.-G.). U. S. 1,793,136, Feb. 17.

Electrolytic production of compounds containing active oxygen. JOHANNES ECKELL (to I. G. Farbenind. A.-G.). U. S. 1,792,633, Feb. 17. See Brit. 313,124 (*C. A.* **24**, 792).

Metal hydroxides by electrolysis. R. S. CARRERAS. Brit. 338,178, July 9, 1929. Hydroxides of Zn, Cu, Sb and other metals (other than Bi hydroxide and white lead) are obtained by use of an anode of the metal the hydroxide of which is to be formed, in a dil. soln. of an electrolyte such as $NaClO_3$ or $KClO_3$ satd. with CO_2 (the electrolyte being continuously withdrawn from the cell without removal of the pptd. hydroxide and returned after resatn. with CO_2). Various details of app. and procedure are described.

Apparatus for electrolyzing fused alkali metal halides. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Ger. 517,256, May 15, 1924.

Apparatus for preparation of light metals by electrolysis of their fused halogen salts. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 142,518, Aug. 23, 1929.

Formation of gang by the decomposition of electrolytic solutions within the rock layers. SIEMENS-BAUUNION G. M. B. H., KOMM.-GES. (Michael Müller, inventor). Ger. 514,818, Jan. 17, 1929. Rocks not contg. a natural electrolyte are impregnated with Na_2SiO_3 so that SiO_2 is freed on electrolysis. The process can be used for petrifaction.

Aluminum production. COMPAGNIE DE PRODUITS CHIMIQUES ET ELECTROMÉTALLURGIQUES ALAIS, FROGES ET CAMARGUE. Brit. 338,084, March 15, 1929. A mixt. of AlF_3 and Na or K carbonate or hydroxide is used instead of cryolite as a flux in the electrolytic reduction of alumina. Various details, proportions, etc., are given.

Protective layers of lead peroxide. SIEMENS & HALSKE A.-G. (Walter Birett and Johannes Fischer, inventors). Ger. 514,621, Oct. 23, 1927. Anode conductors are given a protective coating of PbO_2 by electrolysis in an alk. soln. of a Pb compd. contg. also such O-contg. org. compds. as aldehydes, ketones, ales or their derivs. Examples mention baths contg. NaOH, hydroquinone and PbO, or NaOH, acetone, AcH and PbO, or NaOH, fruit sugar and PbO.

Bleaching shellac. OLGA MYLO NÉE ROSENHAGEN. Ger. 517,096, May 12, 1929. A soln. of shellac is treated with a soln. of a suitable salt, *e. g.*, NaCl, and the mixt. is electrolyzed with stirring and cooling. Preferably, the electrolysis is begun with a weak current, which is afterward strengthened. An automatically operating app. is described.

Treating hydrocarbons in an electric arc. I. G. FARBENIND. A. G. (Otto Eisenhut, inventor). Ger. 514,592, Dec. 15, 1925. App. for subjecting satd. hydrocarbons, *e. g.*, CH_4, to the elec. arc to produce unsatd. hydrocarbons, *e. g.*, C_2H_2, is described. Cf. *C. A.* **24**, 1586.

Acetylene and hydrogen production in the electric arc. OTTO EISENHUT (to I. G. Farbenind. A.-G.). U. S. 1,794,004, Feb. 24. See Fr. 674,459 (*C. A.* **24**, 2385).

Electric furnace. DET NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRIE. Ger. 514, 575, May 7, 1926. Details of the electrodes are given.

Electric induction furnace. EDWIN F. NORTHRUP (to Ajax Electrothermic Corp.) U. S. 1,795,136, March 3. Elec. features.

Electric induction furnaces. SIEMENS-SCHUCKERTWERKE A.-G. (Rudolf G. Berthold, inventor). Ger. 517,348, July 17, 1926. Details of the current feed are described.

Electric resistance furnace. HERBERT J. MCCAULEY. U. S. 1,794,310, Feb. 24. Structural features.

Electric arc furnace for alloying or refining metals. EMILIEN BORNAND and HANS A. SCHLAEPFER. Ger. 517,285, Mar. 1, 1928.

Electric annealing furnace. AKT.-GES. BROWN, BOVERI & CIE. Swiss 142,004, Sept. 17, 1929.

Electric furnace for smelting metals. EMIL F. RUSS. U. S. 1,793,137, Feb. 17. Structural features.

Electric-furnace reduction of alumina. VEREINIGTE ALUMINIUMWERKE A.-G. Brit. 337,995, Nov. 27, 1928. A furnace is continuously charged automatically in accord with the quantity of alumina which is reduced to metal in the bath, the charging hopper being mounted on a hollow anode and discharge from it being controlled by a current-indicating device.

Closed tiltable electric furnace suitable for iron and steel production. EMIL G. T. GUSTAFSSON and BENGT I. NOREN (to Hampus G. E. Cornelius). U. S 1,794,455, March 3. Structural features.

Melting finely divided dry materials such as iron oxide in an electric induction furnace. EDWIN F. NORTHRUP (to Ajax Electrothermic Corp.). U. S. 1,794,863, March 3. Lumps of cond. material such as pure iron which are large enough to be separately heated by induction in passing an a. c. about the charge are mixed with the charge.

Producing carbide-forming metals such as titanium, vanadium, chromium, iron or manganese. TURE R. HAGLUND. U. S. 1,794,401, March 3. Ores such as oxides of the metals named are fused in an elec. furnace together with added reducing agent including lumps of material contg. bauxite, a basic refractory oxide of lower m. p. than the ore, such as CaO, and carbonaceous reducing material. A cement may be produced as a by-product.

Electric furnace with carbide resistances. R. C. BENNER and G. J. EASTER (to Carborundum Co. and C. E. Hawke). Brit. 338,131, Dec. 7, 1928. Various structural details are described of furnaces which may have resistances of Si carbide or B carbide surrounded by a body of granular carbon such as crushed petroleum coke.

Electromagnetic stirring device for furnaces for the electrolysis of fused aluminum salts. HANS THOMA. Ger. 514,919, Dec. 4, 1928.

Device for electrically heating and for spraying molten metals for coating surfaces. WM. S. RICE and CHARLES M. SAEGER, JR. U. S. 1,792,551, Feb. 17. Structural features.

Electrode mounting for electric furnaces or electrolytic cells. A. FRANCHINI (to P. Girod). Brit. 338,371, Aug. 27, 1929. Structural features

Lattice cathodes. RAGUHN-ANHALTER METALLOCHEREI M. B. H. Ger. 514,716, June 24, 1926. Lattice cathodes for the electrolysis of alkali chlorides are described.

Coating cathodes with alkaline earth metal oxides. FRITZ TÖDT. Ger. 514,606, Apr. 8, 1928. The glowing cathode is coated with alk. earth metal oxides, especially BaO, by electrolysis in an aq. bath of alk. earth metal salt contg. CO_3 ions and heating the carbonate deposit so formed to glowing.

Cathode for rotary flame arcs. GEORGES GAUTIER, LEON LE BOZEC and RAYMOND DUBOIS. U. S. 1,793,605, Feb. 24. A cathode comprises a hollow annular ring in which a cooling fluid flows continuously and a winding immersed in the fluid which is supplied with elec. current and has its axis the same as that of the ring.

Glowing cathodes. SIGNUM A.-G. Swiss 142,281, Aug. 6, 1929. Glowing cathodes are made with a core of non-readily fusible metals. This is heated with one or more alkali metals in the absence of O to form a surface alloy, which is then oxidized to complete the cathode.

Incandescent cathode for electric discharge tubes. ANTON E VAN ARKEL and JOHANNES BRUIJNES (to N.-V. Philips' Gloeilampenfabrieken). U. S. 1,794,810, March 3. Cathodes are formed with a metallic core such as Ni, W, Mo or Pt and a surface consisting of a nitride of at least one of the elements Ti, Zr and Hf.

Luminous electrical discharge tube and associated cooling device. JACQUES RISLER (to Risler Corp. of America). U. S 1,793,720, Feb. 24. Structural features.

Electric gas-cleaners. METALLGES. A.-G. (Heinrich B. Rüder, inventor). Ger. 517,261, July 18, 1929. Means is described for keeping the high-tension insulators dry by supplying radiant heat.

Electric gas-cleaners. METALLGES. A.-G. (Kurt von Eberhard, inventor). Ger. 517,262, Oct. 5, 1929. Details of the discharge electrode and its mountings are described.

Electric gas-cleaning apparatus with parallel-plate precipitating electrodes. METALLGES. A.-G. (Jakobus R. Gies, inventor). Ger. 517,067, June 8, 1928.

Hammer device for gas-cleaning electrode. SIEMENS-SCHUCKERTWERKE A.-G. (Alexander Kaufmann, inventor). Ger. 517,263, June 26, 1928.

Electric gas-purification plant. METALLGESELLSCHAFT A.-G. Ger. 514,587, Dec. 9, 1928. Addn. to 511,643 (*C. A.* **25**, 1169). Details of cleaning the electrodes by shaking.

Electric gas-purification plant. SIEMENS-SCHUCKERTWERKE A.-G. (Richard Heinrich, inventor). Ger. 514,650, July 31, 1927. Details of the pptg electrodes are given.

Chamber for the electric purification of gas. SIEMENS-SCHUCKERTWERKE A.-G. (Richard Heinrich, inventor). Ger. 514,820, Mar. 10, 1926. The pptg. surfaces are formed of tin plates.

Apparatus for electrical precipitation. CARL W. J. HEDBERG and HARRY A. WINTERMUTE (to Research Corp.). U. S. 1,794,074, Feb. 24. Structural features.

Apparatus for electrical precipitation of suspended particles from gases. LODGE-COTTRELL, LTD., and L. LODGE. Brit. 337,642, Nov. 29, 1929. Structural features.

Apparatus for electrical precipitation of suspended particles from gases. ME-

TALLGES. A.-G. and LODGE-COTTRELL, LTD. Brit. 337,318, Feb. 15, 1930. Various details are given of an app. in which the gas travels in circular or spiral paths.

Apparatus for electrical precipitation of suspended particles from gases. WILHELM HOSS (to International Precipitation Co.). U. S. 1,794,615–16, March 3. Structural and electrical features.

Apparatus for electrical precipitation of suspended particles from gases. EVALD ANDERSON (to International Precipitation Co.). U. S. 1,793,664–5, Feb. 24. Structural features of electrodes are described.

Apparatus for electrical precipitation of suspended particles from gases. INTERNATIONAL PRECIPITATION CO. and LODGE-COTTRELL, LTD. Brit. 337,685, Jan. 14, 1930. Structural features.

Apparatus for electrostatic precipitation of suspended particles from gases. NATIONAL CARBON CO. Brit. 337,389, Nov. 14, 1928. A collecting electrode is formed (preferably in the shape of a tubular chamber) from coke flour and tar extruded and baked at 900–1400° or machined from solid or perforated blocks of C.

Electrical resistance units. LINWOOD T. RICHARDSON and EDGAR M. SCHMIEL (to Cutler-Hammer, Inc.). U. S. 1,793,829, Feb. 24. Resistance units are formed by surrounding a resistor such as a helical wire with an enclosure such as tubular casing spaced from the resistor, filling the space between the resistance and enclosure with loose granular MgO, hydrating the latter by the action of water and heating the unit to expel H_2O. U. S. 1,793,830 relates to a similar process in which the MgO is hydrated and heated subsequently to reform MgO.

Flexible electric conductors. W. W. RICHARDSON. Brit. 338,215, Jan. 9, 1930. Insulated wires or bare wires laid in spiral paths of different diams. are embedded in rubber and the composite assembly is vulcanized. Various details of manuf. are described.

Apparatus for electrical tests to identify various materials. MARTIN E. SIMON and JOHN A. O'CONNOR (O'Connor to Simon). U. S. 1,793,970, Feb. 24. It is stated that different chem. elements, org. or inorg. compds. and biol. organisms may be identified and distinguished by a described arrangement of elec. app. including a response circuit assocd. with a control circuit with the system critically adjusted so that a characteristic response is produced when a particular substance is brought in active relationship with the control circuit. For example, a known substance, which is the substance it is desired to distinguish in the unknown matter, is placed in electrostatic relation with the control circuit and the response circuit is adjusted to a balanced condition, that is, on the point of oscillation. The normal oscillations may then be suppressed so that there is no sound heard in the loud speaker or telephones, and this condition is disturbed whenever an element for which the circuit is tuned is placed in electrostatic relation with said circuit. In this manner, the particular element may be detected by an audible signal in the loud speaker.

Electric system for temperature control. ANDRE CHAGNAUD (to Établissements Poulenc Frères). U. S. 1,795,008, March 3. Structural and elec. features.

Supplying artificially ionized oxygen for ventilation or other purposes. FRANK E HARTMAN (one-third each to Fred H. Montgomery and W. Ray Montgomery). U. S 1,793,799, Feb. 24. An elec. app. is described for producing ionized O and O_3, with the former in relatively large ratio to the latter.

Incandescent electric lamps. D. K. WRIGHT (to British Thomson-Houston Co., Ltd.). Brit. 337,782, Feb. 18, 1929. Finely divided W is inserted into the bulb of a device such as a lamp, before its sealing, to enable deposits to be rubbed off its inner surface. Various details of manuf. of a projection lamp are described. Cf. *C. A* **24**, 795.

5—PHOTOGRAPHY

E. P. WIGHTMAN

Role of dyes in the progress of photography. A. SEYEWETZ. *Photo-Revue* **43**, 33–4, 53–4(1931); cf. *C. A.* **25**, 1746.—The methods used to fix dyes to the Ag image include (1) those in which the Ag is converted into a chem. compd. capable of acting as a mordant and also capable of fixing the dyes proportionally to the opacity of the Ag deposit; (2) those in which there is formed with the Ag a compd. that will produce a dye by reacting with certain org. compds. In the first method the Ag image is converted into (*a*) simple and double halide salts, (*b*) simple and double Ag ferrocyanides.

(*c*) compds. of Ag with Cr, (*d*) the thiocyanates of Ag and of Cu or (*e*) compds. of Ag formed with quinone in the presence of an alkali metal bromide. H. D. RUSSELL

An abnormal phenomenon of photographic plates. F. E. ROSS. *Astrophys. J.* **73**, 54(1931).—The reversal of low densities on astronomical plates is noted. This phenomenon has a direct bearing on astronomical photography and photometric measurements. H. R. BRIGHAM

Study of some photographic reducers. G. ROBIN. *Sci. ind. phot.* [2], **2**, 24–6(1931). —A systematic study of a number of photographic reducers has been made. All are found to decrease contrast. Permanganate with acid is very close to a proportional reducer; $(NH_4)_2S_2O_8$ attacks more strongly the high densities. L. A. STAIB, JR.

Utilization of film scrap. KURT BRATRING. *Nitrocellulose* **2**, 25–9(1931).—A description of com. processes of regeneration for photographic purposes, recovery of Ag and celluloid, removal of the galatin layer, recovery of gelatin, soln. of celluloid backing alone, treatment of film having protective coatings over the gelatin and utilization of colored, opaque and safety film. E. M. SYMMES

Additive or subtractive effects of two successive exposures. R. LANDAU. *Sci. ind. phot.* [2], **2**, 1–4(1931).—When panchromatic film used for sound recording was given a second exposure under a step wedge subsequent to the exposure received in the sound-recording app., anomalous results were obtained. Subsequent investigation disclosed the following: (1) A very short preliminary exposure (10^{-4} sec.) diminishes sensitivity. (2) Panchromatic film shows the effect. (3) The short exposure must precede the longer one. (4) Polarized light is not essential to the effect noted. (5) The first exposure may produce densities as high as 0.6. L. A. STAIB, JR.

Diminution of the time of exposure and improvement of the detail of radiographs by application of a special after-exposure process. E. HAEGER. *Fortschr. Gebiete Röntgenstrahlen* **42**, 233–52(1930).—A process is described in which the latent images of x-ray films are intensified by application of the Becquerel effect (after-exposure in yellow and green light) after desensitizing the material in a soln. of pinakryptol green (1:5000) for 2 min. As a result, further decrease of the exposure times to radiation is possible. In consequence of the great intensification, the detail of a poorly exposed film is improved. The combination of the intensification and developmental processes is of considerable advantage since, by this procedure, variations of exposure can be compensated for to a considerable degree. Tray development must be employed for this process. E. LINCKE

Second reversal and the Herschel effect with solarized images. W. LESZYNSKI. *Phot. Ind* **28**, 1412–6(1930).—The literature contains evidence of the presence and the absence of the second reversal in different types of emulsions. It is easy to show that the second reversal may or may not occur in the same emulsion. An ordinary emulsion exposed behind a gray wedge shows no second reversal, but the same emulsion previously exposed to solarization in different light and then further exposed under the gray wedge shows a second reversal. Reference is made to the work of Luppo-Cramer, and the second reversal is discussed in relation to uniformity of intensity of exposure, intermediate exposure, the use of red filters for studying the Herschel effect and the necessity for their purity or lack of fogging power. C. E. MEULENDYKE

Peculiar phenomena obtained with mercuric chloride-treated plates. A. REVCHLER. *Bull. soc. chim. Belg.* **39**, 374–8(1930).—Photographic plates treated for a short time in 0.002% $HgCl_2$ soln., touched with the finger tips and given a light exposure show a black mark after development where the pressure was applied. A plate treated with the $HgCl_2$ soln., exposed to light, then touched with the finger tips and developed shows little or no image where the fingers touched. The effects of varying the sequence of $HgCl_2$ treatment, pressure marking and light exposure are discussed. A method of chemically obtaining photographic impressions on money, printed matter, etc., is described. The piece of money or page of printed matter to be reproduced is kept in intimate contact for 2 to 3 hrs. with a sheet of paper which was previously impregnated with $HgCl_2$ and dried. The metal object or printed page, slightly mercurized by the vapor, is removed from the paper and placed in contact with sensitive film or paper for a period of 20 hrs. The film or paper is then given an exposure to light, wetted with water and developed. A negative image of the metallic relief or the printing is thus obtained. L. E. MUEHLER

A photochemical polarizer. FRITZ WEIGERT AND FRITZ STIEBEL. *Naturwissenschaften* **19**, 108(1931).—By irradiation of a photographic transparent gas-light plate with red polarized light the effect of negative induced photodichroism is obtained on direct development. However, by treating the undeveloped plate with CrO_3 (Albert, Luppo-Cramer method) and irradiating subsequently with diffuse natural red light,

positive induced dichroism is obtained on development. The polarized initial exposure with the CrO_3 treatment had changed the sensitive film to a photochem. polarizer. The effect is a support for the micelle theory of latent image and was predictable from it. It is expected that the same Albert reversal could also be obtained with highly sensitive, coarse-grained emulsions. B. J. C. VAN DER HOEVEN

Determination of the general and color sensitivity of negative materials. C. EMMERMANN. *Schweiz. Photo-Ztg.* **32**, 220–2, 224–9(1930).—The principles and the application of the methods of Scheiner, of Eder-Hecht and of Hurter and Driffield are discussd for the detn. of the general and color sensitivity of neg. materials. H. D. RUSSELL

Optical sensitizing of silver halide by colloidal silver. S. E. SHEPPARD. *J. Franklin Inst.* **210**, 587–607(1930).—Various theories on the optical sensitizing of Ag halides are discussed. It is suggested that optical sensitizing by colloidal Ag (Becquerel effect) is primarily due to sensitized photoelec. emission by Ag amicrons and ultramicrons. Sensitized photoelec. emission of composite metal films is considered as due to minute Volta condenser fields. Self-fields as origins of sensitized photoelec. effects are considered in relation to the Becquerel and Weigert effects with Ag halides. E. P. WIGHTMAN

Alteration of orthochromatism by pinakryptol. K. HAIDRICH. *Photofreund* **11**, 50–2(1931).—Sensitometric tests were made on a series of plates. The same exposure was given each plate. One plate was desensitized with a normal pinakryptol bath before development. A rodinal developer (1:20) was used. The normal plate was developed for 5 min. and the desensitized plate for 6 min. in total darkness. With the Gevaert SSS plate a loss of 5° Scheiner resulted; with Gevaert Super-Press 8° Scheiner; with Agfa Isochrome 9° Scheiner and with Agfa Allocyanine plates 15° Scheiner. It was also found that desensitizing affected the color sensitiveness of an emulsion as follows:

Agfa Isochrome plates

Blue	green	yellow
3° S.	3° S.	3° S. loss in speed

Gevaert Super-Press plate

Blue	green	yellow
6° S.	8° S.	8° S. loss in speed

Gevaert SSS plate

Blue	green	yellow
1° S.	4° S.	3° S. loss in speed

Allocyanine plate

Blue	green	yellow	red
14° S.	11° S.	16° S.	16° S.
loss in speed		increase in speed	

A. K. WITTMER

Desensitizing. NEUGEBAUER. *Photofreund* **10**, 360–3(1930).—Sensitometric tests were made to det. loss of speed by the use of a desensitizer (pinakryptol green as a preliminary bath). A desensitized plate compared with untreated plate showed a loss of speed when both were given equal development. If the developing time is doubled, an increase of speed is obtained which approaches but does not usually equal that of the untreated. If a desensitizer is used two to three times the normal exposure should be given. A. K. WITTMER

Desensitizing. H. DÜRR. *Photofreund* **10**, 441–3(1930); cf. Neugebauer (preceding abstract).—D. directs attention to several publications by O. Mente, A. Hübl, K. Jacobsohn, M. L. Dundon, J. I. Crabtree and B. H. Carroll on desensitizing. All authors claim no loss of speed if a plate or film is developed a little longer than an ordinary plate which is not given a desensitizing treatment. A. K. WITTMER

Desensitizing. LÜPPO-CRAMER. *Photofreund* **11**, 7–9(1931).—Exception is taken to the view of Neugebauer (2nd preceding abstract) that the use of desensitizers results in a loss of speed. L.-C. cites some of his own papers in support of his statements. A. K. WITTMER

Desensitizing. NEUGEBAUER. *Photofreund* **11**, 27(1931).—In reply to Lüppo-Cramer (preceding abstract) N. states that the newer emulsions may act differently with a desensitizer from emulsions made in 1920–1925. A. K. WITTMER

Chromium and sulfur intensification of negatives and prints. H. D. POWER. *Camera Craft* **38**, 73(1931).—The method consists in bleaching the negatives or prints in a soln. of 2% $K_2Cr_2O_7$ plus 1.5% strong HCl and substituting a freshly prepd. 2% soln. of Na_2S for the developer. The use of a bisulfite soln. is mentioned to discharge the color of the dichromate to give satisfactory results. G. W. WILHELM

Some properties of fine-grain developers for motion picture films. H. C. CARLTON AND J. I. CRABTREE. *Trans. Soc. Motion Picture Eng.* **13**, 406–44(1929).—Graininess can be lessened by (1) increasing the sulfite, (2) decreasing the rate of development and (3) increasing the degree of development. Borax developers do not give aerial fog, but also do not produce images with less graininess. Tables showing the effect of compn., agitation, aging and exhaustion and time-fog curves are given. A. N. H.

Borax developer characteristics. H. MOYSE AND D. R. WHITE. *Trans. Soc. Motion Picture Eng.* **13**, 445–52(1929).—A sulfite concn of 75 g. per l. gives grain-free images with high speed. The effect of borax is due to its alky. Metol rather than hydroquinone does the developing. Hydroquinone tends to increase fog. Renewing a borax developing bath brings back the development rate but not the detail-giving power which has been lost through bromide accumulation. ANN NICHOLSON HIRD

Neutral and acid amidol developer. C. EMMERMANN. *Phot. Chronik* **37**, 138–40 (1930).—Acid amidol is a somewhat slower developer than neutral amidol. Emulsion speed is not affected. Acid amidol also produces more fog. Halation is more noticeable with the acid amidol. A. M ROBINSON

Warm tone developing, selenium and sulfur toning. C. EMMERMANN. *Phot. Chronik* **38**, 10, 15–7(1931).—The use of pyrocatechol, glycine, hydroquinone and eikonogen without sulfite as warm tone developers is briefly discussed Se and S toning are also briefly described. A. M. ROBINSON

"Uvatypie" and its paper prints in natural colors. K. WOLTER. *Camera (Luzern)* **9**, 185–90(1931). Three-color sepn. negatives are made in a repeating back camera. A print is made from each of these on dichromated gelatin film by exposure through the support. A wash-off relief is then produced on each film. The reliefs are dyed in the three complementary colors and a three-color imbibition print is made upon gelatin-coated paper. This imbibition process remedies the poor shadow quality and variation in successive prints characteristic of other imbibition processes. This end is achieved by rinsing the dyed reliefs in distd. water before making the prints and by employing dye solns. of the correct degree of dispersity. Diffusion of the dye in the printing paper is prevented by incorporating casein into the gelatin. M. W. S.

Positive material for motion pictures in color. R. LANDAU. *Kinotechnik* **13**, 12–(1931). A hypothetical color-printing process is described in which 3 fine-grained photographic emulsions are to be made, each of a uniform grain size differing from the other two When developed in the same developer, each emulsion is to give a colloidal Ag deposit of one of the 3 complementary printing colors. The emulsions are to be coated in superposition upon a common film support. The top and bottom emulsions are not to be color-sensitized, while the middle one is to be orthochromatic or panchromatic. All are to be impregnated with a yellow screening dye. The lowest is to give a red Ag deposit, the middle one a yellow deposit and the top one a blue deposit. The film is exposed 3 times, each time through one of the three-color sepn. negatives: to the green filter neg., through the support, with blue light; to the red filter neg., from the emulsion side, with blue light; to the blue filter neg., with yellow light The film is then to be developed to obtain a pos. in 3 colors. Instead of making the emulsions of 3 grain sizes, they may be of one grain size, and the developer, preferably contg. a Ag halide solvent, may be altered in compn. as it penetrates the successive emulsions. M. W. SEYMOUR

Photographic detection of the asymmetrical angular distribution of twice reflected electrons (RUPP) **3.** Direct photography of ionization in insulating substances (GEMANT) **3.** Method for preparing photographs of Petri dish cultures by direct contact printing on photographic paper (BUCHHOLZ, LEWIS) **11C.**

NEWENS, FRANK R.: **The Technique of Colour Photography.** London: Blackie and Son, Ltd. 101 pp. 4s. 6d., net.

Photographic emulsions. S. E. SHEPPARD and E. P. WIGHTMAN (to Kodak, Ltd.). Brit. 337,323, Feb. 25, 1929. Stability of emulsions is improved and any tendency to fog is corrected by adding small proportions of compds. such as saccharin, diacetamide, phthalimide, pyrrole derivs. such as succinimide and ring compds. such as those contg. the pyrazolone, pyrazole, pyrazolidone or *v*-triazole ring. Cf. *C. A.* **24**, 3720.

Photosensitive material. H. D. MURRAY, D. A. SPENCER and COLOUR PHOTOGRAPHS (BRITISH & FOREIGN), LTD. Brit. 337,868, Aug. 24, 1929. A water-impermeable cellulose ester such as a nitrocellulose or cellulose acetate compn., or fibrous

material such as paper or fabric coated or impregnated with such an ester, has its surface rendered water-permeable by superficial de-esterification and is then impregnated with a light-sensitive salt such as a compd. of Ag, Cr or Fe or a diazo compd. Various details of treatment are described.

Apparatus for developing photographic materials such as sensitive paper by a developing gas such as ammonia. ADOLPH LANGSNER (to Eugene Dietzgen Co.). U. S. 1,794,909, March 3. Structural features.

Bromide printing. OTTO TREICHEL. Ger. 495,920, Sept. 26, 1928. Bromide prints without spots or wrinkles are produced by having at most 1.8% alkali and at least 1.8% Na_2SO_3 in the $KHSO_3$ and citric acid developer. A suitable developer contains metol, hydroquinone, Na_2SO_3, Na_2CO_3, $KHSO_3$, citric acid and KBr.

Blue prints. KALLE & Co. A.-G. (Maximilian P. Schmidt and Rudolf Zahn, inventors). Ger. 517,159, July 24, 1926. A compd. (other than a dye) showing strong absorption in the ultra-violet, *e. g.*, Na 6-phenyl-2-aminopseudoaziminobenzene-3,4′-disulfonate, is added to inks or crayons for making drawings from which blue prints are to be prepd. Clearer reproduction results.

Screen for use in photoengraving. JOHN W. IPPERS (one-half to Joseph Deutsch). U. S. 1,794,693, March 3. In forming a patterned, irregularly reticulated, hardened colloid screen for photoengraving, a dichromated colloid layer is exposed to actinic rays at predetd. areas and again exposed to light in its entirety, and swelling is then effected by development with suitable colloid-swelling liquids, followed by washing and drying.

Photomechanical printing surfaces. EUSTACE B. ELDRIDGE (one-half to John A. Haeseler). U. S. 1,793,070, Feb. 17. For producing a substantially grainless printing surface from a latent Ag image in a colloidal material, capable of being printed from as in collotype printing, the exposed plate or film carrying the latent image is developed with a developer such as a dil. amidol soln. which reacts upon all the light-affected Ag salt in the colloid proportionately to the amount of light to which the Ag salt has been exposed, but the action of which is so feeble as to produce an extremely faint and tenuous image lacking d. and depth which will be composed of very minute quantities of reduced Ag held in suspension in the colloid, and the colloid is chem. hardened in the presence of the Ag (suitably by the action of an aq. soln. formed from $CuSO_4$, KBr, $K_2Cr_2O_7$ and chromic acid).

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

The atomic weight of iodine. The analysis of iodine pentoxide. GREGORY P. BAXTER AND ALBERT Q. BUTLER. *J. Am. Chem. Soc.* **53**, 968–77(1931).—I_2O_5 produced by dehydration of HIO_3 contains less I (and more O) than corresponds to the theoretical formula. I_2O_5 of normal compn. is difficult, if not impossible, to prep. Conclusions based upon its actual compn. are not sufficiently reliable for work of high precision, as attested by the at. wt. obtained, 126.905. B. A. SOULE

Principles of the structure of boron-hydrogen compounds. Addendum. E. WIBERG. *Z. anorg. allgem. Chem.* **195**, 288(1931).—Because of an abbreviation of ms. (cf. *C. A.* **25**, 1751) omission was made from the table of properties of B_2H_6 and C_2H_4 that the statement regarding addn. of Na to the ethylenic bond relates to derivs. of ethylene and that the assumption of addn. of hydrogen halides, halogens and compds. of the type HOX to B_2H_6 relates to a previous hypothesis on boron hydride substitutions elaborated by W. A. P. SACHS

The chemistry and metallurgy of beryllium. G. MALCOLM DYSON. *Chem. Age* (London) **24**, 228–30(1931).—A review. E. H.

The separation of beryllium and aluminum oxides. A. TRAVERS AND SCHNOUTKA. *Compt. rend.* **192**, 285–7(1931).—Methods available are based on these facts: (1) BeO dissolves in a soln. of NH_4HCO_3 while Al_2O_3 does not. (2) Solubilities in alk. solns. are different. (3) Solubilities in a boiling soln. of $NaHCO_3$ are different. (4) A basic acetate of Be is sol. in $CHCl_3$. (5) Al is pptd. by 8-hydroxyquinoline. T. and S. offer the following methods: (1) The bisulfites are evapd. to dryness on a steam bath and extd. Al forms an insol. oxide but Be does not. (2) $Be(HSO_3)_2$ ppts. in boiling soln. in the presence of traces of H_2SO_4 but redissolves on cooling, while $Al(HSO_3)_3$ does not. (3) Be forms a complex with $NaHSO_3$ which is completely decomposed by boiling and Be does not form compds. with Al at p_H 4. An extensive bibliography is given. A. L. T.

Polytherms of ternary systems which in addition to water contain an alkaline sul-

fate and manganous sulfate. III. A. BENRATH. *Z. anorg. allgem. Chem.* **195**, 247–54 (1931); cf. *C. A.* **24**, 3159.—The polytherms are detd. for the systems $MnSO_4$–Tl_2SO_4–H_2O, $MnSO_4$–$(NH_4)_2SO_4$–H_2O, $MnSO_4$–Rb_2SO_4–H_2O. The solid phases present are $MnSO_4.Tl_2SO_4.6$ aq., $2MnSO_4.Tl_2SO_4$, Tl_2SO_4 and corresponding salts of NH_4 and Rb, in addn. to the mono-, penta- and heptahydrate of $MnSO_4$ in each system. The temp. range was 0–100°. K does not form the double salt $MnSO_4.K_2SO_4.6$ aq., while with Cs the salt $2MnSO_4.Cs_2SO_4$ is lacking. H. STOERTZ

Ternary systems. IX. Sodium iodate, sodium nitrate and water. ARTHUR E. HILL AND JOHN E. DONOVAN. *J. Am. Chem. Soc.* **53**, 934–41(1931); cf. *C. A.* **23**, 4616.—The soly. of $NaIO_3$ in water is given for temps. from 5° to 50°. Isotherms in the ternary system $NaIO_3$–$NaNO_3$–H_2O are given at 5°, 25° and 50°. The stable hydrates are $NaIO_3.5H_2O$ below 20° and $NaIO_3.H_2O$ above this temp. In the ternary system, the double salt, $2NaIO_3.3NaNO_3.15H_2O$, appears below 9.8°. **X. Magnesium iodate, magnesium nitrate and water.** ARTHUR E. HILL AND SAMUEL MOSKOWITZ. *Ibid* 941–6. –The soly. of $MgIO_3$ in water is given from the eutectic (−0.36°) to +90°. In addn. to the deca- and tetrahydrates, previously known, the anhydrous form is shown to exist in contact with water above 57.5°. Isotherms in the ternary system $Mg(IO_3)_2$–$Mg(NO_3)_2$–H_2O are given at 5°, 25° and 50°. No double salts are found in this temp. range. B. E. TIFFANY

Behavior of sodium sulfate crystals toward cold ethyl alcohol and methanol. M. A. RAKUZIN. *Z. Krist.* **73**, 115–6(1930).—Treatment with 95% EtOH affords a powder consisting of thenardite; with MeOH dehydration, but not powder formation, occurs. B. C. A.

The chlorides of sulfur. T. M. LOWRY. *Z. Electrochem.* **36**, 733–4(1930); cf. *C. A.* **24**, 4441.—Dielec. consts. for mixts. of S_2Cl_2 and Cl_2 in the solid state show the presence of SCl_4. F.-p. curves indicate the sepn. of solid S_3Cl_4, SCl_2 and SCl_4. Surface tension, d., light absorption and parachors show the liquid mixts. behave as a ternary system: S_2Cl_2–SCl_2–Cl_2. O. M. SMITH

Sulfur fluoride. KĀRLIS ŠTRENKS. *Acta. Univ. Latviensis Kim. Fakultat. Serija* **1**, 233–60 (in German 261 2)(1930).—The interaction of AgF and S yields Ag_2S and S_2F_2, a colorless gas with an odor similar to that of SO_2 or S_2Cl_2; it fumes in air and is very toxic to the organism; it is decomposed by water, yielding S, H_2SO_3 and HF, it attacks glass, even at low temps., and yields S, SiF_4, SOF_2 and SO_2; its formula has been proved by analysis and density detn. It attacks quartz, and consequently the physical constants reported by Fischer and Jaeneckner (*C. A.* **23**, 5014) are incorrect, it does not corrode Sn, steel, Fe or Pt. A. L. HENNE

The decomposition of hypobromous acid. FRIEDRICH POLLAK AND ETELKA DOKTOR. *Z. anorg. allgem. Chem.* **196**, 89–112(1931).—HBrO is best prepd by treating concd. $AgNO_3$ soln. with pure Br_2, followed by vacuum distn. A concn. greater than 0.3 *M* will be unattainable because of the decompn. of HBrO. Prepns. of HBrO always contain its decompn. products, $HBrO_3$ and Br_2, which fact has not always been considered in previous work. If HBrO is prepd. from $AgNO_3$ it contains HNO_3 which comes over during the distn. This HNO_3 can be detd. analytically only by the nitrometer method. The nitrometer method of Klemenc and Hayek (*C. A.* **21**, 3285), which is especially suitable for a small quantity, was modified for use in the presence of the Br compd. present in the prepn. Inexplicable irregularities in the distn. and the decompn. of HBrO make it almost impossible to prep. a soln. of definite concn. This decompn. is greatest during the first part of the distn. The decompn. of HBrO proceeds by 2 simultaneous, independent reactions: (I) $5HBrO \longrightarrow HBrO_3 + 2H_2O + 2Br_2$ and (II) $4HBrO \longrightarrow O_2 + 2H_2O + 2Br_2$. In the dark, at 15°, reaction (I) predominates. H ions were not observed to influence it. Bubbling of N_2 through the soln. did not affect it. $HBrO_2$ may be involved transiently in the decompn., but it did not appear in measurable concn. R. H. LOMBARD

Composition of the deposit forming on zinc immersed in copper sulfate solution. I. A. GALECKI AND J. TOMASZEWSKI. *Roczniki Chem.* **10**, 437–68(in German 468–71) (1930); cf. following abstr.—The coherence of the deposit forming on zinc rods immersed in $CuSO_4$ soln. increases with stirring and with the concn. and decreases with the acidity of the solns.; at the same time the color of the deposit becomes lighter. The deposit contains two constituents: (a) a metallic, flexible, red, yellow or white coating, possessing either a dull or a polished surface; and (b) a dark brown to black powdery or flocculent ppt. The former consists of metallic Cu and Zn in various proportions, probably both as a mixt. and as alloys, while the latter contains oxides of the two metals, as well as basic sulfates and the free metals. B. C. A.

Composition of the deposit forming on zinc immersed in copper sulfate solution. II.

A. GALECKI AND J. TOMASZEWSKI. *Roczniki Chem.* **10**, 601–27(in German 628–9)(1930); cf. preceding abstr.—With the increase of temp. the content of Cu in the ppt. decreases and the content of Zn increases. The neg. balance of the reaction is greater the higher the temp. Temps. at which the expt. was performed (18–50°) had no noticeable influence on the appearance and color of the ppt. The addn. of $ZnSO_4$ to the reaction system lowers the percentage of Zn in the ppt. by an amt. proportional to a certain extent to the amt. of $ZnSO_4$ added. The neg. balance of the reaction increases with added $ZnSO_4$. In a quiet electrolyte the addn. of $ZnSO_4$ has in general no noticeable influence on the external form and consistency of the ppts.; in a stirred soln. addn. of $ZnSO_4$ causes the formation of more fragile ppts. A considerable portion of Zn is most probably in the form of basic compds. which dissolve in NaOH. In general, the ppt. varies greatly in form and compn. with varying conditions. J. KUČERA

The non-existence of the subiodides of bismuth, BiI_2 and BiI. V. CAGLIOTI. *Gazz. chim. ital.* **60**, 933–5(1930).—For a long time there has been evidence both for and against the existence of Bi iodides lower than BiI_3 (cf. *Pogg. Ann.* **107**, 601(1859); Guthmann and Herz, *Z. anal. Chem.* **56**, 422(1908); Marino and Becarelli, *C. A.* **7**, 1457), and it was therefore of interest to exam. BiI_3 and the reputed compds., BiI_2 and BiI, by x-rays BiI_2 and BiI were prepd. with the app. used by Marino and Becarelli (*loc. cit.*) for studying the system Bi–I. The powder method was used in the x-ray examn., and the rontgenographs are reproduced. No evidence of the existence of any compd. other than BiI_3 was obtained. A mixt. of BiI_3 and Bi in proportions corresponding to BiI_2 showed no interference lines of Bi, so that the substance which was supposed to be BiI_2 is probably a mixt. of BiI_3 and Bi. A mixt. of BiI_3 and Bi in proportions corresponding to BiI showed the lines of BiI_3 and Bi. This obscuring of the lines of one substance in a mixt. is being studied further, and it has already been found that Cu contg. 7% of Co_2Si does not show the interference lines of the Co_2Si. C. C. DAVIS

Silicic acids. II. W. DILTHEY AND W. NAGEL. *J. prakt. Chem.* **129**, 178–88 (1931); cf. *C. A.* **23**, 1585.—The earlier expts. were repeated with various solvents and at lower temps. The H_2O content of the silicic acids obtained depends on the temp. and is not much influenced by the proportion of the Ph_3COH in the reaction. At −18° to −20° and with 4.5 mols. of Ph_3COH a product with a H_2O content of 27% is obtained when using $CHCl_3$ as a solvent. This compares with the product obtained with Et_2O at 35°. The 27% is too high to assume the presence of the meta acid. With CCl_4 at −15° to −18° a product with 20% H_2O is obtained This value is too low for the meta acid No ortho acid could be obtained. The soly. of the silicic acids, detd by dialysis, was not over 6% and decreased with age. The splitting off of H_2O is probably not intra- but inter mol. E. SCHOTTE

The existence of violet tungsten oxide, W_4O_{11}. E. TARJAN. *Naturwissenschaften* **19**, 166–7(1931). Expts in H_2-H_2O mixts. between 700° and 1000° on W oxides did not confirm the existence of W_2O_5 (blue), in agreement with the results of Reinders and Vervloet (*C. A.* **18**, 349). Inside the range of existence of this compd. (Chaudron, *C. A.* **14**, 2451) a violet product was obtained of compn W_4O_{11} (oxidation value 1.76 to 1.84%), *i. e.*, between WO_3 and W_2O_5. Above W_4O_{11} blue reduction products are formed at low H_2 concns. with oxidation values of a few tenths of a percent; below W_4O_{11} no blue products could be obtained, further reduction gave WO_2 and W. W_4O_{11} can be prepd. from WO_2 as well as from WO_3 at 15 to 30% H_2 at 900°. In CO-CO_2 mixts W_4O_{11} can be made inside the alleged W_2O_5 limits from either side (900°, 25% CO_2) (cf. van Liempt, *C. A.* **16**, 1530). W_4O_{11} crystallizes in red-violet needles with a metallic luster; it has a triclinic lattice different from that of WO_3 and WO_2. Ignition of a pressed mixt. of $3WO_3 + 1WO_2$ in an inert atm. gives the violet oxide in a manner similar to the prepn. method of W bronzes. The relationship with these bronzes is furthermore evident from the chem. resistivity and the metallic cond. ($\rho = 2 \cdot 10^{-4}$ ohm cm. for a pressed sample, sintered at 1200°). Leiser (*C. A.* **2**, 760) has described the electrolytic prepn. of W_4O_{11}; earlier erroneous data on the W oxides are partly due to retarded reduction processes and hence apparent equilibria. B. J. C. v. D. H.

The preparation of complex bromine derivatives of quinquevalent tungsten. H. PAULSSEN-v. BECK. *Z. anorg. allgem. Chem.* **196**, 85–8(1931); cf. Collenberg, *C. A.* **12**, 2501.—The following complex bromotungstites were prepd. by methods which in principle consisted in treating the complex K, NH_4 or Na oxalotungstites with concd. HBr, sepg excess oxalate and bromide and treating with a soln of the bromide of the metal or base in HBr: *Dirubidium pentabromotungstite*, $Rb_2(WOBr_5)$, bright, olive-brown crystals; *dicesium pentabromotungstite*, $Cs_2(WOBr_5)$, greenish-yellow powder of microscopic octahedra; *monopyridine tetrabromotungstite* $(C_5H_5NH)(WOBr_4)$, brownish-green

powder of square platelets; *diammonium pentabromotungstite*, $(NH_4)_2(WOBr_5)$, olive-green octahedra, decompd. on drying; *monotetraethylammonium aquotetrabromotungstite*, $[(C_2H_5)_4N](WOBr_4.H_2O)$, bright green powder of cryst. scales. The 3 series of salts, $Me^I_2(WOBr_5)$, $Me^I(WOBr_4.H_2O)$ and $Me^I(WOBr_4)$, are analogous to the previously known chlorotungstites and have the same cryst. form as the latter, although their color is more toward brownish yellow. The bromotungstites are less sol. in concd. HBr than are the corresponding chlorotungstites in concd. HCl. The color of the bromotungstite soln. is green; that of the chlorotungstite soln. is blue. Treatment of Na oxalotungstite with concd. HF gives a violet-colored soln. The bromotungstites are more susceptible to hydrolytic decompn. than are the chlorotungstites, but they may be preserved in dry CO_2. R. H. LOMBARD

Sulfur derivatives of perrhenic acid. WILH. FEIT. *Z. angew. Chem.* **44**, 65–6 (1931).—H_2S is passed into a satd. soln. of $KReO_4$. The soln. becomes yellow in color at first, but after a day's flow of gas becomes deep brown, almost opaque. When no further change is observed the H_2S is removed by boiling, and the soln. is carefully concd. by evapn. at 35°. When only about $^1/_5$ the original volume remains, small brown crystals sep. which appear to be $KReO_4$ contg. a small quantity of thio salt. On further concn. the crystals sepg. become even darker and are accompanied also by a dark brown ppt. which is probably a sulfide of Re. The soln. is finally dried without further sepn. of crystals to a dark brown mass which is easily sol. in H_2O and contains 14–15% S. It is a mixt. of $KReO_3S$, $KReO_2S_2$, $KReOS_3$, $KReS_4$. A soln. of this residue is treated with N/20 Tl_2SO_4 and the dark brown ppt. is filtered, washed and dried at 35°. Analysis gave the compn. $TlReS_4$. The filtrate from this still contained Re and S, and on further treatment with Tl_2SO_4 yielded a bright yellow cryst. ppt. of $TlReO_3S$. A soln. of this salt on treatment with HCl gave a fugitive red color followed by sepn. of S, showing that free $HReO_3S$ is unstable. H. STOERTZ

The hypophosphites of cesium and rubidium. L. HACKSPILL AND J. WEISS. *Compt. rend.* **192**, 425–6(1931) The hypophosphites of Cs and Rb (PO_2H_2M) are similar to those of the other alkalies. Their density and their affinity for H_2O increase with their at. wt. and their decompn. with heat is similar. AMY LEVESCONTE

Study of the absorption spectra of various series of rare earth double nitrates. DENIS W. PEARCE AND J. ALLEN HARRIS *Trans Roy. Soc. Can* [3], **24**, Sect. 3, 145–51(1930). A study was made of the various double nitrates of the rare earth elements to ascertain if it was possible that some might be more efficient than others in effecting a sepn. of these elements, particularly of Il from Nd and Sa. From a study of the relative intensities of the most characteristic absorption band of each element it would appear that: (1) The double NH_4 nitrates afford the most efficient sepn. of La and Pr from Nd. (2) The double Mg and double Co nitrates are of the same efficiency in their relative sepns., no definite sepn being possible by these salts. The ease of crystn. renders them useful for preliminary sepn. of the more basic members. (3) The double Mn nitrates are to be recommended as a means for sepg Sa and Nd. (4) The double Cu nitrates appear to effect a reversal of soly from the usual serial order of the double nitrates, *i. e.*, according to at. wts. (5) Pb appears to produce little effect on the sepn. of the more basic members of the Ce group. Indications are afforded that $Pb(NO_3)_2$ may be helpful in the sepn. of Il. J. W. SHIPLEY

Observations on the complex cyanides of nickel, copper and chromium. W. GLUUD AND W. RIESE. *Ber. ges. Kohlentechnik* **3**, 452–9(1931) In strongly ammoniacal solns., $K_4Fe(CN)_6$ decomposes as follows under the influence of $AgNO_3$. First one mol of NH_3 is taken up: $K_4Fe(CN)_6 + NH_3 \longrightarrow KCN + K_3[Fe(CN)_5NH_3]$. The $AgNO_3$ removes the cyanide and takes the reaction to the right in steps as follows: $K_3[Fe(CN)_5NH_3] + NH_3 \longrightarrow KCN + K_2[Fe(CN)_4(NH_3)_2]$; $K[Fe(CN)_3(NH_3)_3]$, $[Fe(CN)_6(NH_3)_4]$ and finally $Fe(CN)_2$ are formed. Similar reactions occur with Ni salts, $K_2[Ni(CN)_4]$ being converted into $K[Ni(CN)_3NH_3]$, $[Ni(CN)_2(NH_3)_2]$ and finally also into $[Ni(NH_3)_3CN](CN)$ and $[Ni(NH_3)_4](CN)_2$. Similar results are obtained with Cu and Cr compds. With $(NH_4)_2S_x$, these complex cyanides lead to the formation of thiocyanates, the Ni salts furnishing typical reactions. If the formation of $[Ni(NH_3)_4](CN)_2$ is assumed, this reacts with $(NH_4)_2S_x$ to form NiS and NH_4CNS. The corresponding Cu and Cr salts are formed somewhat less readily. The presence of concd. NH_4OH suppresses any considerable thiocyanate formation. Varied reactions are given with $FeSO_4$, the Ni salts giving a ppt. of $Fe[Ni(CN)_4]$, no Fe whatever replacing Ni in the anion. With Cu salts, however, ferrocyanides are produced and also the following compd., $KFe[Cu(CN)_4]$. With the complex Cr cyanide the reaction is as follows in alkaline soln.: $K_3[Cr(CN)_6] + 3KOH \longrightarrow Cr(OH)_3 + 6KCN$. The excess of KCN then forms a ferrocyanide with the ferrous salt. H. STOERTZ

Phase-rule studies on metallic thiocyanates (OCCLESHAW) 2.

LÖWENSTEIN, ELSE: **Über Subhaloide der Homologen des Quecksilbers.** Freiburg i. B.: Speyer und Kaerner. 32 pp. M. 1.50.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Quantitative emission spectrum analysis in any percentage without calibration curve. G. SCHEIBE AND O. SCHNETTLER. *Naturwissenschaften* **19**, 134(1931).—Certain phases of a method previously described (*C. A.* **24**, 5622) have been checked by the use of a Pt absorption wedge. The results are briefly discussed. B. J. C. v. D. H.

Physical methods in the chemical laboratory. XVII. A method for increasing the accuracy in quantitative emission spectral analysis and its testing. G. SCHEIBE, C. F. LINSTRÖM AND O. SCHNETTLER. *Z. angew. Chem.* **44**, 145–51(1931); cf. *C. A.* **25**, 1440.—The photographic plate, with respect to its applicability for spectrographic analyses, was studied, with particular attention to the dependence upon the wave lengths. With the aid of a thermoelec. photometer, which is suitable for technical purposes, the behavior of the intensity of the lines was carefully studied, and as a result of this study a procedure was developed which will serve for the spectrographic detn. of varying quantities of substances with an accuracy of about 3%. W. T. H.

Colorimeters, spectrophotometers and nephelometers. C. DIGAUD. *Ann. chim. anal. chim. appl.* **13**, 1–5, 33–54, 65–72(1931).—This is an account of the marked advances that have been made in the field of analytical chemistry, particularly with respect to applying the principles of modern phys. chemistry. A discussion of the theory underlying all processes ending with visual observation begins with an explanation of the anatomy of the eye, then turns to photoelec. cells, thermoelec. couples, thermoelec piles and photographic plates and finally compares the sensitiveness of the eye with that of the photoelec. cell and of the photographic plate. The app. and its use are described in detail. W. T. H.

Nephelometric titrations. II. Standard-solution end-point. CLYDE R. JOHNSON. *J. Phys. Chem.* **35**, 830–5(1931).—It has been pointed out (*C. A.* **25**, 1178) that there is a possible error in the equal-opalescence end point in nephelometric detns. To avoid this possible error it is proposed to work to a different end point called the "standard-soln. end-point." For this 2 sets of standard solns. are necessary In the titration of Cl^- with $AgNO_3$, *e. g.*, the necessary quantity of $AgNO_3$, to within a few tenths of a mg., is added, and then both Cl^- and Ag are detd. nephelometrically in the supernatant soln. by use of solns. satd. with AgCl ppt. as standards. W. T. H.

The stability of standard arsenious acid solutions. IV. TANANAEV. *Ukrainskii Khem. Zhurnal* **5**, Sci. Pt., 217–26(1930).—(1) Standardized arsenious acid loses the strength of its titer through oxidation to arsenic acid. The oxidation rate is directly proportional to the alky. of the soln. A 0.1 *N* soln. of As_2O_3 in 1 *N* NaOH suffers a daily loss in titer equaling approx. 0.176% of As_2O_3. (2) Weakly alk. solns. (p_H = 7–9) remain unchanged for 1.5 years. (3) $NaHCO_3$ free from Na_2CO_3 is most suitable and can be prepd. by passing CO_2 through the soln. (4) Solns. of As_2O_3 prepd. from the pure chem. remain sterile and do not form AsH_3. B. S. LEVINE

Systematic qualitative analysis with small quantities of cations. A. SCHEINKMANN. *Z. anal. Chem.* **83**, 176–88(1931).—Instead of starting with 1 g. or more of material, only 0.1–0.15 g. of sample is taken, and the reagents are added in drops, an unnecessary excess being avoided. The first group of AgCl, $PbCl_2$ and Hg_2Cl_2 is treated with a little 5% KNO_3 soln., in which $PbCl_2$ is more sol. than in water, but is otherwise analyzed in the conventional manner. For pptg. the second group, a satd. soln. of H_2S is used, which is prepd. daily but which is much more convenient to use than the gas itself. The sulfide ppt. is treated with KOH soln. to dissolve the sulfides of As, Sb, Sn and Hg. From this soln. HgS is pptd. by NH_4Cl, and the sulfides of As, Sb and Sn by AcOH, after which this subgroup is analyzed conventionally. The sulfides of Group II which are insol. in KOH soln. are dissolved in HCl and H_2O_2 and treated with NH_4OH, after which the procedure is normal. In Group III, the NiS and CoS left undissolved by dil. HCl are dissolved by treatment with AcOH and H_2O_2, which is decidedly advantageous. In testing for Al, both the morin and alizarin tests are used For Zn the resorcinol and ferrocyanide tests are used, and for Mn the green fusion test and the treatment with PbO_2 and HNO_3 are prescribed. The filtrate from this

Fe-Al group is evapd. to dryness after making acid with HCl and ignited with oxalic acid, whereby insol. $BaCO_3$, $SrCO_3$, $CaCO_3$ and MgO are formed together with water-sol. alkali carbonates. In this way the baneful effects of excess NH_4 salts are overcome. These are the principal ways in which the procedure differs from that ordinarily used. Several lab. devices are shown which will be found useful. W. T. H.

Mercurimetric studies. O. TOMÍČEK AND O. PROČKE. *Collection Czechoslov. Chem. Comm.* **3**, 116–25(1931).—Votoček found that $Na_2Fe(CN)_5(NO).2H_2O$ could be used as indicator in titrating Cl^- and Br^- but not I^- with $Hg(NO_3)_2$. With respect to the soly. of the Hg nitroprussiate and the extent of its ionization, but little data are available. It would seem probable that the molar soly. is not greater than 2×10^{-5} and that its soly. product is below 10^{-9}. The physicochem. studies here described lead to the same conclusion that the molar soly. is below 5×10^{-5}. Other observations made will be given a practical application in a subsequent paper. W. T. H.

Dimethyl-*p*-phenylenediamine hydrochloride for the determination of small quantities of chlorine. KNUT ALFTHAN. *Finska Kemistsamfundets Medd.* **36**, 109–12 (1927).—The reagent gives with Cl the same shade of red color as methyl red (dimethylaminoazobenzene-*o*-carboxylic acid) shows in acid soln. The water to be tested is treated with the reagent, and the resulting color is compared with those of known solns. of methyl red. In testing drinking water, 0.01 mg. Cl can be detd. J. RYSELIN

Indirect estimation of silicon in 48 to 52 percent ferrosilicons. G. T. DOUGHERTY. *Ind. Eng. Chem., Anal. Ed.* **3**, 158–9(1931).—The direct detn. of Si in Fe-Si requires 1.5–2 days. To avoid car demurrage, an indirect method has been worked out requiring but 0.5 day and which depends upon carefully treating the sample with HF and H_2SO_4 in a Pt or palau crucible and weighing the residue after evapn. and ignition. W. T. H.

Lithium chloroplatinate and the separation of potassium from sodium and lithium by the unmodified, original, Fresenius method. G. FREDERICK SMITH AND A. C. SHEAD. *J. Am. Chem. Soc.* **53**, 947–57(1931).—$Li_2PtCl_6.6H_2O$, prepd. from Li_2CO_3 and H_2PtCl_6, and twice recrystd., can be used to advantage for pptg. K_2PtCl_6. The ppt. then has the normal concn., which is not true when H_2PtCl_6 is used as precipitant. Moreover, the ppt. is stable at 200–260°, whereas the ppt. produced with H_2PtCl_6 decomposes above 160°. For washing the K_2PtCl_6 ppt., 80% EtOH is recommended. The errors due to the use of H_2PtCl_6 are due to decompn. of the reagent, which does not take place when recrystd. Li_2PtCl_6 is used. W. T. H.

Quantitative determination of calcium, magnesium and phosphorus in feedstuffs and cattle excreta. Improved technic. H. P. MORRIS, J. W. NELSON AND L. S. PALMER. *Ind. Eng. Chem., Anal. Ed.* **3**, 164–7(1931).—Detailed directions are given for fusing the ash with soda, extg. the melt with HCl and water and detg. Ca, Mg and P in the soln. To avoid the necessity of removing all SiO_2, the CaC_2O_4 ppt. is titrated rather than weighed. The value of the method is shown by exptl. data. W. T. H.

The selenious acid method for the determination of zirconium. STEPHEN G. SIMPSON AND WALTER C. SCHUMB. *J. Am. Chem. Soc.* **53**, 921–33(1931).—For decompg. Zr minerals, the Muehlberg method of fusing with Na_2O_2 and C is recommended, the fusion being made a second time with any residue which is insol. in acid. After the fusion, ext. the melt with water and reject the soln. of sol. Na salts. Dissolve the residue in HCl, filter if necessary and evap. the soln. to fumes with 25 cc. of 18 *N* H_2SO_4. Cool, dil. and filter off SiO_2. Make the filtrate ammoniacal, filter and wash slightly. Promptly dissolve the ppt., which contains ZrO_2, in 15 cc. of 12 *N* HCl, add 20 cc. of EtOH, heat nearly to boiling, dil. to 500 cc., again boil and add 20 cc. of 10% H_2SeO_3 soln. When the liquid is clear, filter off the ppt. of $4ZrO_2.3SeO_2.18H_2O$, and after very slight washing, dissolve it in 15 cc. of 12 *N* HCl. Add 20 cc. of 3% H_2O_2 to reduce any quadrivalent Ce, dil. to 500 cc. and again ppt. with H_2SeO_4. Digest the 2 filters used for the Zr ppts. with 40 cc. of hot 10% oxalic acid and add the soln. to the main ppt. contg. Zr. Dil. to 200 cc., heat to boiling and add 12 cc. of 6 *N* HCl. After it has stood at least 10 hrs., filter and wash the ppt. with 2.5% oxalic acid dissolved in 0.24 *N* HCl. To the filtrate contg. the Zr add 30 cc. of 18 *N* H_2SO_4 and evap. till all the $C_2O_4^{--}$ has been destroyed, as shown by no more evolution of CO and CO_2. Filter off any Se ppt. and make the filtrate ammoniacal. Filter off the $Zr(OH)_4$ ppt., and after a little washing dissolve it in 15 cc. of 12 *N* HCl, add 20 cc. of 3% H_2O_2, dil. to 500 cc., add 20 cc. of 10% H_2SeO_3 soln., filter, ignite the basic Zr selenite over the blast lamp and weigh as ZrO_2. W. T. H.

Separation of calcium and magnesium by the molybdate method. R. C. WILEY

Ind. Eng. Chem., Anal. Ed. **3**, 127–9(1931).—$CaMoO_4$ is insol. in water, whereas $MgMoO_4$ is quite sol. Quantities of Ca ranging from 20 to 50 mg. can be sepd. from 12–70 mg. of Mg by treating the soln. (0.05 *N* in Ca, 0.075 *N* in Mg, or less) at the boiling temp. with a slightly ammoniacal soln. of NH_4 molydate (about 0.4 *N*), added dropwise. The pptn. of the Ca is complete if boiling is continued till the supernatant liquid is clear. The ppt. can be weighed as $CaMoO_4$ after drying at 130° for 30 min. The Mg can be detd. as $MgNH_4PO_4$ in the filtrate. W. T. H.

Potentiometric determination of iridium. Sho-Chow Woo and Don M. Yost. *J. Am. Chem. Soc.* **53**, 884–8(1931); cf. *C. A.* **25**, 1725.—The iodometric method, in which quadravalent Ir is reduced to the bivalent Ir by means of I^- in 0.1–0.2 *N* HCl and the liberated I_2 is titrated with $Na_2S_2O_3$, gives good results if benzene is used to show the end point. Good results are also obtained by direct titration with $TiCl_3$. The potentiometric end point is clear in 50 cc. of 0.1 0.2 *N* HCl if 2–3 g. of NaCl is added and the $TiCl_3$ is added slowly toward the last. Directions are given for prepg. chloroiridic and chloroiridous acids. W. T. H.

Method for the separation and gravimetric determination of osmium. Raleigh Gilchrist. *Bur. Standards J. Research* **6**, 421–48(1931).—Os, when present as chloride or bromide, can be pptd. completely as hydrated OsO_2 from boiling solns. of p_H 1.5–6.3. The presence of alkali chloride or sulfate does no harm. The marked tendency to spatter when the oxide is heated can be overcome by impregnating the ppt. with NH_4Cl. Os, when reduced in H_2 and cooled to room temp. in CO_2, remains unattacked by air for a long time. Os, when present as bromosmate or alkali osmate, can be volatilized completely as OsO_4 by boiling in 10% HNO_3. When present as chlorosmate, it cannot be eliminated easily in this way, but from concd. H_2SO_4 near its b. p. the OsO_4 can be distd. off from the latter compd. but less readily from the former compds. By a mixt. of H_2SO_4 and HNO_3 it is possible to effect complete volatilization from either type of compd. No RuO_4 is volatilized from 40% HNO_3 or from concd. H_2SO_4 alone, but from concd. H_2SO_4 contg. HNO_3 or from concd. HNO_3 alone RuO_4 is gradually volatilized A soln. of 6 *N* HCl satd. with SO_2 is a suitable reagent for receiving the distd. OsO_4. It is necessary, however, to evap. repeatedly with concd. HCl to decompose the Os sulfite compd. completely. The thiourea test for the detection of Os can be made sensitive to 0.02 mg. of Os in 100 ml. of soln. In the app recommended for the detn. of Os, all connections are of ground glass. The 700 ml. distg. flask carries a tap funnel in the neck, a glass tube extending to the bottom of the flask for the entrance of the gas, and a gas exit tube leading to a conical flask, contg. 150 ml. of 6 *N* HCl which has been satd. with SO_2. In this first receiver practically all of the OsO_4 is condensed, but for the sake of safety there are 2 other flasks provided, each contg. 50 ml. of the SO_2-HCl soln. Between the first and second flasks, a small tap funnel is fused into the gas line, through which addnl. HCl-SO_2 can be introduced if necessary. It was found necessary to keep the stopcock of this funnel greased, but otherwise no lubricant is advisable. To the soln. in the distg. flask, dild. if necessary with 100 ml. of water, add 40 ml. of 7.5 *N* HNO_3 and flush out the funnel with 10 ml. of water. Pass a slow current of air through the app. and heat the soln. to boiling. Distil for 1 hr. This should be sufficient to remove Os from alkali osmate or bromosmate, but 7–8 hrs. are necessary if chlorosmate is present. In this case it is better to distil from concd. H_2SO_4, or if Ru is absent, from concd. H_2SO_4 to which a little concd. HNO_3 has been added Unite the several portions of HCl-SO_2 and evap. on the water bath in an unetched beaker. Digest the residue with 10 ml. of concd. HCl for 15 min. and evap. a second time. Repeat the digestion and evapn. 3 times more. Take up the final residue in 150 ml. of water and heat to boiling. Add $NaHCO_3$ soln. until a ppt. appears and suddenly coagulates. Add bromophenol blue indicator and enough more $NaHCO_3$ soln. to impart a faint, bluish color to the soln. Boil 5–6 min., filter through a Munroe crucible and wash the ppt. with hot 1% NH_4Cl. Cover the washed ppt. with solid NH_4Cl, add a few drops of the wash liquid, and apply suction to get the NH_4Cl into the ppt. Wipe off the coating of NH_4Cl that comes through the crucible, cover with a Rose crucible lid of quartz and heat in H_2. At the end heat strongly for 10 min. and allow to cool in H_2, finally replacing with CO_2. Weigh as metallic Os. W. T. H.

New method for reduction of tin and antimony prior to titration. B. S. Evans *Analyst* **56**, 171–7(1931).—A soln. of 5 g. $NaH_2PO_2.H_2O$ in 6 *N* HCl, added to about 100 ml. of 6 *N* HCl contg. 0.002–0.05 g. of Sn and 1 cc. of satd. $HgCl_2$ as catalyst, will reduce all Sn^{++++} to Sn^{++} if boiled 15 min. in an atm. of CO_2. Then, by dilg. with 2.5 times as much of a boiled and cooled soln. of 10 g. citric acid, 0.4 g. KI and some starch, the Sn can be detd. by titration with standard I_2. Particular pains were taken to avoid all contact with air. The reduction of Sb to the tervalent condition takes

place with 5 min. boiling and without the use of any catalyst. Fe, Cu and As must be removed. The results obtained were excellent. W. T. H.

Determination of lead as chromate in presence of perchloric acid. D. J. Brown, Joseph A. Moss and John B. Williams. *Ind. Eng. Chem., Anal. Ed.* **3**, 134–5(1931).—$PbCrO_4$ is less sol. in dil. $HClO_4$ solns. than it is in dil. HCl or dil. HNO_3. Directions are given for carrying out the gravimetric and volumetric detn. of Pb as $PbCrO_4$, after first removing HCl and HNO_3 by evapn. with $HClO_4$, and 24 results obtained with a 0.5 g. sample of a certain ore contg. 82.04% Pb showed 81.55–82.04%. W. T. H.

Photoelectric microanalysis. Mototarō Matsui and Tōkiti Noda. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 517–8(1930).—Cu in Cu-NH_3 soln. can be detd. by measuring with a photoelec. cell the amt. of light transmitted through such a soln. The light source was an incandescent lamp. The thickness of the Cu-NH_3 soln. was 12 cm. If I is the current from the photo-elec. cell when the Cu-NH_3 soln. is in the light path, and I_0 the current when H_2O is substituted for Cu-NH_3 soln., a quant relation exists between I_0-I or $log(I_0/I)$. The photoelec. current was reduced 73.5% when a 0.00063 N Cu-NH_3 soln. was substituted in the cell by H_2O. An accuracy of about 5% was possible. The photoelec. cell used was of the A-filled Cs type. The tension was 80 v. in series with a 5 megohm protector. E. M. Symmes

Detection of cadmium. J. Stanton Pierce and W. T. Forsee. *Ind. Eng. Chem., Anal. Ed.* **3**, 188–9(1931).—Instead of using KCN or Fe powder before testing for Cd in the usual qual. scheme, it is recommended to boil the neutral or slightly acid soln. for 3–5 min. with 1–5 g. of fine Ni powder which serves to reduce the Cu. Then, after filtering, a soln. is obtained which can be tested for Cd by adding AcOH and H_2S. W. T H.

Detection of zinc and cadmium by the cyanide method. N. A. Tananarv and N. S. Fedulov. *Ukrainskii Khem. Zhurnal* **5**, Sci. Pt., 213–6(1930).—To a soln. of the substance add a considerable excess of NH_4OH, heat and filter. If Mn is present add H_2O_2 and filter. To the filtrate add a soln. of KCN until the colors due to Ni, Co and Cu disappear. Add Na_2S and heat. Wash the ppt. 3 or 4 times with water. A white ppt. which completely dissolves in an excess of KCN indicates the presence of ZnS_2 alone. If the ppt is yellow, CdS is present alone or in conjunction with ZnS. To establish this fact add an excess of KCN and acidify the soln. with AcOH. A white ppt. or turbidity indicates the presence of ZnS. There is some incomplete exptl. evidence to show that the method works in the presence of Pb and Sb when the NH_4OH added is not too strong. B. S. Levine

Qualitative tests for zinc, copper and silver. A. Sergeev. *Ukrainskii Khem. Zhurnal* **5**, Sci. Pt., 227–9(German abstract 230)(1930).– Add a few drops of concd. NaOH and some pulverized Al to the soln., and stir with a glass rod. A change in color and a swelling of the Al particles indicate the presence of Zn. To a neutral or slightly ammoniated soln. of the substance add some Hg. Formation of gray or silvery needle-like crystals indicates the presence of Ag. Heat the end of a narrow glass test tube and apply to a drop of the soln. to be tested. Heat the end of the tube for about 2 min. in the lower part of a Bunsen flame. A copper-orange filament is formed if Cu is present. B. S. Levine

Pyrognostic assaying of platinum and palladium. Herculano Calmon. *Rev. brasil. chim.* **1**, 84–5(1929).—C. describes his method for the detection of Pd and Pt, which is based on the incandescence that is observed in the ashes of the filter paper or in asbestos threads that have been impregnated with the salt to be investigated, heated to a red heat and put in the flame of illuminating gas, alc. vapors or a mixt. of EtOH and sulfuric ether. Working on a metallic web is recommended. The reaction is very sensitive. John M. Ladino

New method for the titration of iron according to J. Knopp. Otto Rothe and Aggêo Pio Sobrinho. *Rev. brasil. chim.* **1**, 129–49(1929).—For detg. Fe^{++}, the following conclusions are drawn: The use of diphenylamine indicator with dichromate is superior to the use of permanganate. The metals of the second group must be removed with H_2S, especially As and Sb. Min. quantities of Cu cause no error. Colloidal silica or other metals such as Hg and Sn need not be removed. Colloidal Pt caused by fusion of the oxide in a Pt crucible is harmful, making the use of permanganate necessary. A Ag crucible is to be preferred. Care must be taken not to reduce any AgCl, the reduction of which takes place quite readily. John M. Ladino

Determination of aluminum oxide in aluminum and its alloys. A. M. Shandorov. *Tzvetnuie Metallui* **1930**, 672–9; *Chimie & industrie* **25**, 37(1931).—S. verified the accuracy of the Cl-gas method, using a gas-heated, transparent quartz tube so as to follow the reaction, which is strongly exothermic and requires careful regulation of the

heating and Cl feed. It is essential that the Cl be free from O_2 and water. After the chlorination, the boat is ignited at 1000° to burn the C. The analysis requires about 1 hr. S. found 0.07–0.10% Al_2O_3 in com. Al and 0.07–0.21% in duralumin.
A. PAPINEAU-COUTURE

Analysis of metal containing copper. I. Analysis of copper. H. ARAI, C. UYETSUKI AND S. TACHIBANA. *Repts. Imp. Ind. Research Inst., Osaka, Japan* **11**, No. 15 (1930).—The procedure for the electrolytic detn. of Cu is given. F. I. NAKAMURA

Supplement to the new iodometric method for determining vanadium in alloy steels and in ferro-vanadium. W. WERZ. *Z. anal. Chem.* **83**, 161–4(1931); cf. *C. A.* **25**, 51.—For the decompn. of excess $(NH_4)_2S_2O_8$, 15 min. is inadequate, but 30–35 min. should suffice. The reaction between Fe^{+++} and I is so slow in the presence of H_3PO_4 that as much as 3 g. Fe liberates I_2 corresponding to not more than 0.2 cc. of 0.05 *N* $Na_2S_2O_3$ when 0.2–0.3 g. of KI is added; with 1–2 g. of KI about twice as much I_2 is liberated. When oxalic acid is present, more I_2 is set free. With highly alloyed steels, this effect is less, and by keeping the concn. of the H_3PO_4 soln. low, the interference of Mn is lessened and the addn. of oxalic acid is unnecessary. There is, on the other hand, no danger of any Cr being oxidized by the persulfate when Ag ions are absent. When the Cr is high in an alloy steel, the Cr carbide should not be removed until after the oxidation with HNO_3. If this carbide is not removed, it will tend to reduce vanadate later in the analysis. The persulfate should not be added until the nitrous fumes have all been boiled off from the soln. The procedure as modified is as follows: Dissolve 1–3 g. of steel in a 500-cc. Erlenmeyer flask in 25 cc. of H_3PO_4 (*d.* 1.70) and 200 cc. of water (10–15 min.). Oxidize with concd. HNO_3 and add 5 cc. in excess. Boil a few min. to remove nitrous fumes. Filter off any undissolved carbide. Add 10 cc. of 5% $(NH_4)_2S_2O_8$ soln. and boil 35 min. Add 25 cc. more of H_3PO_4, cool to room temp., add 2–10 cc. of 0.2 *N* KI soln., shake well and after 5 min. titrate with 0.05 *N* $Na_2S_2O_3$ in a vol. of about 200 cc. W. T. H.

Use of microanalysis in the streak test [for precious-metal alloys]. R. STREBINGER AND H. HOLZER. *Mikrochemie* [N. S.], **2**, 264–70(1930).—The streak test is made on a roughened depression in a microscope slide. When the alloy is chiefly Ag, the streak is dissolved in HNO_3 on the slide, and the Ag is pptd. as chloride and removed by centrifuging. The filtrate is evapd to dryness, the residue dissolved in water, and 1 drop of K mercurithiocyanate soln. is added; green crystals indicate the presence of Cu and brown crystals the presence of Cd. For the examn. of a Au streak it is dissolved in aqua regia, the metals are pptd. as sulphides by passing H_2S through the soln. from a capillary tube, and the ppt. is collected in a microcentrifuge, washed, digested with $(NH_4)_2S$ to remove the Au, and dissolved in HNO_3. Min. drops of the soln. are tested for Pb by addn. of AcOK and KNO_2 (triple K Pb Cu nitrite pptd.) for Bi with K sulfate (double sulfate pptd.), for Pd with dimethylglyoxime in AcOH, for Ni with the same reagent and NH_3, for Co, Zn and Fe with NH_4 mercurithiocyanate, and for Al with alizarinsulfonic acid. Pt streaks may be similarly tested for the presence of Cu, Pd and Ag; Au is detected by the purple of the Cassius test. B. C. A

Titrimetric determination of small quantities of ammonia, with particular attention to water analysis. S. KÜHNEL HAGEN. *Z. anal. Chem.* **83**, 164–75(1931).—An app. is shown which is suitable for the detn. of free NH_3 in water. One of the principal advantages lies in the avoidance of rubber stoppers and rubber connectors and in the use of a quartz condenser tube. The NH_3 is caught in a measured vol. of $^1/_{140}$ *N* HCl and the excess titrated with NaOH of the same concn. against an indicator of a 0.01% soln. of methyl red and 0.04% soln. of bromothymol blue in 96% alc. For the detn. of albuminoid NH_3, it is recommended to heat with H_2SO_4 0.1 g. graphite, 0.75 g $HgSO_4$, 1.00 g. $CuSO_4.5H_2O$ and some K_2SO_4, and finally to add Na_2S and NaOH and distil. By the app. and method described, 0.1–0.3 mg. of NH_3 can be detd. with an accuracy of about 5%. W. T. H.

Indirect determination of magnesium carbonate in the presence of calcium carbonate. G. A. PANCHENKO. *Ukrainskii Khem. Zhurnal* **5**, Sci. Pt., 187–95(1930).—Dissolve a weighed sample in an excess of standard acid and titrate the excess. Now add an excess of standard oxalic acid and titrate the excess of the oxalic acid with $KMnO_4$. B. S. LEVINE

The estimation of sodium carbonate in sodium bicarbonate. A. K. BABKO. *Ukrainskii Khem. Zhurnal* **5**, Sci. Pt., 197–206(1930).—When the % of soda in the bicarbonate exceeds 3–4%, it can be detd. by titration against phenolphthalein, if a pure soln. of $NaHCO_3$ and an equal amt. of the indicator are used as a control, or by the method of Simpson with a mixt. of 6 parts of bromophenol blue and 1 part of cresol red

as indicator. If the Na_2CO_3 content is below 3%, a colorimetric detn. is better.
B. S. LEVINE

The oxalate method for the analysis of potassium thiocyanate using the borax titer. N. A. TANANAEV AND N. A. LAZARKEVICH. *Ukrainskii Khem. Zhurnal* **5**, Sci. Pt., 209-12(1930).—By means of the oxalate method, convert KCNS into K_2CO_3 and titrate the latter with acid soln. standardized against borax. B. S. LEVINE

Determination of phosgene. J. C. OLSEN, GEORGE E. FERGUSON, VICTOR J. SABETTA AND LEOPOLD SCHEFLAN. *Ind. Eng. Chem., Anal. Ed.* **3**, 189-91(1931).—Four methods for detg. $COCl_2$ have been studied: (1) absorption in alc. soln. of NaOH and subsequent titration of chloride or of excess NaOH, (2) absorption in ammoniacal $AgNO_3$ soln. and weighing of the AgCl formed after neutralizing with HNO_3, or titration of excess Ag, (3) absorption in a satd. soln of aniline and weighing of the resulting diphenylurea, (4) passing of the $COCl_2$ through a 2% soln. of NaI in acetone and titration of the liberated I_2. Methods (3) and (4) were found reliable in studying decompn. products of CCl_4 mixts. and in samples of $COCl_2$ contg. other Cl compds.
W. T. H.

The separation of phosphoric acid as bismuth phosphate in quantitative analysis. A. KEŠĀNS. *Acta Univ. Latviensis Kim. Fakult. Serija* **1**, No. 4 5, Fasc. 2 Burtnica (in German 121-6)(in Lettish 65-121(1929)).—At room temp., a satd. soln. of $BiPO_4$ in 0.25 *N* HNO_3 contained 0 6 mg. of P_2O_5 in 100 cc. A 0.5 *N* HNO_3 soln. under the same conditions dissolves 2.4 mg. of P_2O_5. In the presence of the halogen or sulfate ions, the soly. increases, because a portion of the $BiPO_4$ becomes basic BiOX or $Bi_2O(OH)_2 \cdot SO_4$. This difficulty can be overcome by using solid $BiONO_3$ as the precipitant. The sepn. is so complete that only 0.1 mg. of P_2O_5 in 100 cc. of the soln. remains. The main pptn. is carried out in a 2 *N* or 5 *N* HNO_3 (either hot or cold) by adding the solid $BiONO_3$ and diluting to a strength of 0.5 *N*. The mixt is warmed for 6-8 hrs. on a water bath and allowed to cool until the next day. This insures greater pptn. The cations Ca and Sr should not be present in amts. greater than 70 mg /100 cc of diluted soln., and the other cations, Na, K, Mg, Ba, Zn, Mn, Co, Ni and Fe, in concn. greater than 100 mg./100 cc. of soln RUSSELL C. ERB

A new method for the optical determination of atmospheric ozone. ANDRE I. DUNINOWSKI. *Compt. rend.* **191**, 859 61(1930).—By use of a galvanometer sensitive to 10^{-9} amp., with photographic registration, the distribution curve of solar energy was recorded between 4860 and 12,000 A. U. on several days from August to December, 1929. In interpreting the results it is necessary to consider at some definite wave length the intensity, *I*, the mass of air traversed, *M*, and the atm. d , Δ: colog I = colog $I_0 + m\Delta$. The ozone is detd. in 4 min , and 10 15 detns. should be made at one time, as atm. changes during a series of measurements were the principal source of error. The work was done at Montpelier. The value of *e* varied from 0.20 to 0.36 cm.
GERALD M. PETTY

New method for determining carbon monoxide by combustion with oxygen in the presence of a new catalyzer of two substances. ALBERT SCHMIDT. *Z. angew. Chem.* **44**, 152-5(1931).—I_2O_5 is commonly used for the oxidation of CO but is not very stable at the necessary temp.; it tends to retain the liberated I_2, and but 1 mol. of I_2 is formed by the action of 5CO. Combustion of CO to CO_2, by passing the dry gas over CuO at 300–400°, is always more or less incomplete without a catalyst, but if 1 2 mm. quartz grains are moistened with $Cu(NO_3)_2$ and then ignited, a layer of fine CuO on SiO_2 is obtained which converts CO to CO_2 very efficiently. The SiO_2 tends to adsorb CO, the CuO adsorbs O_2 and the catalyzer does not retain the CO_2 formed, which can be absorbed in $Ba(OH)_2$ soln. An app. is shown which is suitable for detg CO and in which the reaction tube is heated electrically. At the end of the process the excess $Ba(OH)_2$ is titrated. W. T. H.

Determination of hydrochloric acid in the presence of hydrobromic and hydriodic acids. G. G. LONGINESCU AND TH. I. PIRTEA. *Bul. chim. soc. română stiinte* **31**, No. 4/6, 77 87(1930); cf. *C. A.* **25**, 894.—The method described depends upon first pptg. with $AgNO_3$ in dil. HNO_3 and weighing the ppt. This gives the wt. of AgCl together with AgBr and AgI. In a second portion of the same size, the ppt. is kept as far as possible in the beaker and washed by decantation to remove all excess Ag. The ppt. is then heated with 50 cc. of 7-8% NH_3 soln. and treated with a soln. of KBr or HBr, whereby any chloride of Ag is converted into AgBr. This ppt. is also weighed. Finally, when all 3 halides are present, a similar treatment is given to the ppt. except that KI is added after the treatment with NH_3 soln. In this case, the total halide content is detd. as AgI. The purpose of the NH_3 treatment is to dissolve all the AgCl

and part of the AgBr, whereby the KBr or KI soln. becomes more effective in accomplishing the desired conversion. W. T. H.

Microdetermination of the calcium ion. MOUSSERON. *Bull. soc. chim. biol.* **12,** 1014(1930); cf. *C. A.* **25,** 1458.—Ca is pptd. as the salt $K_2CaNi(NO_2)_6$ from which N is reduced to NH_3 and detd. by titration. The amt. of Ca can then be calcd. Fe, Mg, Al, etc., cause less interference in this method than in the tungstate method. From 0.3 to 1.0 mg. Ca can be detd. C. G. KING

A new reagent for fluorides. CAMILLO PERTUSI. *Atti III congresso naz. chim. pura applicata* **1930,** 573-5.—The reagent consists of a soln. of benzidine acetate prepd. from 1.84 g. benzidine, a little concd. HOAc and distd. H_2O to make up to 500 cc., and a 0.02 *N* Hg succinimide soln., mixed in equal parts. The reaction is quite evident with a drop of 0.05 *N* alkali fluoride or 0.00004 g. of HF. The compn. of the ppt. in a complex mol. of 2 mols. of $HFH_2NC_6H_4C_6H_4NH_2HF$ and 1 mol. of HgF_2. E. M. S.

Detection of bromides by the drop method. A. V. PAVLINOVA. *Ukrainskii Khem. Zhurnal* **5,** Sci. Pt., 231(German abstract 232)(1930).—The method is based on the fact that pernitric acid, formed by the interaction of H_2O_2 and HNO_2, liberates Br from bromides. The Br gives a pink color with eosin or fluorescein. The reaction is sensitive to 1:12,500. Chlorides do not interfere with the reaction. Iodides do, but they can be removed with $Na_2S_2O_3$. B. S. LEVINE

Conductometric titration of sulfate and barium. I. M. KOLTHOFF AND TOHRU KAMEDA. *Ind. Eng. Chem., Anal. Ed.* **3,** 129-33(1931).—In the conductometric titration of $ZnSO_4$ with $BaCl_2$ the end point is very poor unless about 30% of alc. is added. In all cases, however, the titration curve bends before the equivalence point is reached. Similar results were obtained in titrating sulfates of K, Na and Li with $BaCl_2$ as well in the reverse titration of $BaCl_2$ with alkali sulfate solns. The end points are reproducible, however, to within about 1% of the Ba or SO_4 content, so that the conductometric method will be useful in the analysis of very dil. solns. The errors are smallest with Li_2SO_4. The cond. of the soln. in the presence of $BaSO_4$ ppt. is greater than when the ppt. is removed, possibly because of the charge residing on the $BaSO_4$ in suspension and because of its influence on the cell const. W. T. H.

Determination of nitrite and sulfite in the presence of one another in salt mixtures and in meat products. E. SZABÓ. *Z. Untersuch. Lebensm.* **60,** 389-95(1930).—The salt is dissolved in a little H_2O, Na_2CO_3 is added and the sulfite pptd. by a cold soln. of $Pb(OAc)_2$. The mixt. is dild. to a known vol., filtered, and an aq. portion taken for the colorimetric detn. of the nitrite by means of *m*-phenylenediamine. The ppt. is washed with cold H_2O, suspended in cold boiled H_2O and the SO_2 detd. by acidification and distn. in a stream of CO_2. Or, the sample may be dissolved in a dil. soln. of $NaHCO_3$ and the SO_2 detd. by the addn. of a slight excess of 0.1 *N* I soln. with back titration with $Na_2S_2O_3$. The air is then removed by a stream of CO_2 and the soln acidified with 1 cc. of 0.1 *N* H_2SO_4, and after 1 min. without disturbance, the free I is titrated with $Na_2S_2O_3$. The stream of CO_2 serves to mix the 2 solns. KI should be added in the second titration only if the amt. of nitrite is in great excess. A max error of approx. ±1 mg. for both detns. was found in solns. of mixts. contg. 65-100 mg. of Na_2SO_3 and 25-100 mg. of $NaNO_2$. Meat samples are extd. with $NaHCO_3$, and the ext. should be free from substances which may interfere with the iodometric titration. C. R. FELLERS

The determination of the sulfite ion in the presence of the thiosulfate ion with the aid of fuchsin. V. E. MALINOVSKII. *Ukrainskii Khem. Zhurnal* **5,** Sci. Pt., 181-6 (1930).—Dissolve 0.34 g. fuchsin in 1 l. of water contg. 1 g. of H_2SO_4 and heat slightly on a water bath. Make a satd. aq. soln. of the substance and dil. 16 times; add 1 drop of 1% phenolphthalein indicator and, if the soln. is alk., carefully neutralize with 0.1 *N* AcOH. To 10-15 cc. of the neutralized soln add a few drops of the fuchsin reagent. Decolorization within the first few min. is a certain indication of the presence of the SO_3^{--} ion. Under the conditions outlined the presence in the soln. of the $S_2O_3^{--}$ ion does not interfere with the reaction. B. S. LEVINE

Determination of ammonium salts by the formaldehyde method. ERMENEGILDO SORRENTINO. *Atti III congresso naz. chim. pura applicata* 552-6(1930).—Five cc. of neutral 40% CH_2O and a few drops of phenolphthalein are added to 20-5 cc. of the NH_4 salt soln., and the mixt. is titrated with 0.2 *N* $Ba(OH)_2$ until a color persists. Results agree well with the theory. Urea, dicyandiamide and guanidine do not interfere. E. M. SYMMES

The simultaneous test for thiocyanate and ferrocyanide anions by the drop method. A. V. PAVLINOVA AND T. N. BAKH. *Ukrainskii Khem. Zhurnal* **5,** Sci. Pt., 233(German abstract 234)(1930).—Place a drop of $FeCl_3$ on a piece of filter paper, follow by a drop

of H_2SO_4 and finally by a drop of the soln. to be tested. In the presence of both anions a central blue spot of Prussian-blue is formed surrounded by a red ring formed by the $Fe(CNS)_3$. B. S. LEVINE

The effect of the nature of the paper upon the sensitiveness of the drop method. A. V. PAVLINOVA AND T. N. BAKH. *Ukrainskii Khem. Zhurnal* **5**, Sci. Pt. 235(German abstract 236)(1930).—Ash-free paper enables one to detect the presence of $K_4Fe(CN)_6$ in $N/8445$ soln., while on ordinary paper the test is sensitive only to $N/5000$ soln. B. S. LEVINE

Poisoning by mercury oxycyanide. A. SARTORI. *Chem.-Ztg.* **54**, 813–4(1930).—An analysis of the viscera, performed 3 months after death, failed to detect the presence of HCN, but showed Hg. A. L. HENNE

Absolute determination of nitrogen in organic compounds. Pregl's micro-method. OTTO R. TRAUTZ AND JOSEPH B. NIEDERL. *Ind. Eng. Chem., Anal. Ed.* **3**, 151–2(1931).—The accuracy of the micro-Dumas method for dctg. N can be increased by using measured vols. of CO_2 and of CuO, applying empirical corrections for air and absorption errors, allowing for adhesion to the walls and taking into consideration the vapor pressure of the KOH soln. over which the N_2 is measured. Detailed directions are given for carrying out an analysis with a few mg. of sample. Thus in one analysis of toluamide the value 10.33% N was obtained, which is correct within 4 parts in 1000 although the observed vol. of N_2 obtained was only 0.321 cc. and the calcd. corrections were 0.012 cc. W. T. H.

A micro-method for the determination of carboxyl groups in organic acids. SHUNJI TSURUMI AND YASABURO SASAKI. *Science Repts. Tôkohu Imp. Univ.*, 1st. Ser., **19**, 681–8(1930).—The carboxyl group in org. acids is detd. within an error of 1% on 2–5-mg. samples by a procedure based on that described by Hunter and Edwards (*C. A.* **7**, 2189). The app. consists of a train, a decompn. vessel, an air chamber and a micro-buret (Flaschentrager, *C. A.* **19**, 3230) in series. The train contains the usual elements for producing pure H_2S. The decompn. vessel (55 mm. × 14 mm. diam.) has an inlet tube reaching the bottom, an outlet tube at the top and a side arm. A curved spatula, which may be rotated, is introduced through a stopper in the side arm. The air chamber is water-jacketed and has 2 2.5-cc. bulbs and a 5-cc. bulb in series. Capillary tubing and stopcocks are used throughout. Charge the decompn. vessel with 1 cc. of carbonate-free NaOH and weigh the sample on a 7-mm. watch glass and support it on the spatula. Sat the NaOH with H_2S from the train and shake to remove excess. Bring the system to atm. pressure and connect it to the buret. Spill the sample by turning the spatula, shake the decompn. vessel till no more gas is evolved and measure the displaced air over water in the buret. A. F. SHEPARD

Analysis of mixtures of hydrogen, methane and ethane. OSWALD J. WALKER AND SOORYA NARAYAN SHUKLA. *J. Chem. Soc.* **1931**, 368–70.—A Töpler pump is connected by means of a 3-way cock to a U-tube which can be cooled by immersion in a bath of liquid air for the removal of the C_2H_6; it is also connected to bulbs contg. "oxidized" Pd sponge for the removal of H_2. The procedure consists, therefore, in condensing the C_2H_6 and measuring the contraction, adsorbing the H_2 by Pd and detg. the CH_4 by difference or by explosion. W. T. H.

Detection of glycerol. M. TRONCOSO SERANTES. *Rev. centro estudiantes farm. bioquim.* **18**, 221–3(1929).—Denigès' method (*C. A.* **22**, 136) and Sanchez' procedure are modified by the use of BaO_2 instead of PbO_2 or MnO_2, as oxidizing agent. B. C. A.

Reactions of glycerol and calcium glycerophosphate. LAD. EKKERT. *Pharm. Zentralhalle* **72**, 85–6(1931).—Various color tests are discussed in connection with the detection of glycerol, notably that involving the use of codeine and concd. H_2SO_4. It appears unnecessary first to oxidize the glycerol to glyceraldehyde or dihydroxyacetone, since by simply putting a layer of concd. H_2SO_4 beneath an aq. soln. of glycerol and codeine a blue or violet color develops. An aq. soln. of Ca glycerophosphate shows like behavior. W. O. E.

Detection of isopropyl alcohol in brandy, spirits, tinctures, cosmetics and liniments by means of piperonal. G. REIF. *Z. Untersuch. Lebensm.* **60**, 243–54(1930); cf. *C. A.* **23**, 5542.—Twenty-five brandies, 40 cosmetics, 124 liniments and various samples of spirits, tinctures, etc., were examd. by the following improved technic: Ten cc. of the sample is distd. on the water bath into a small cylinder immersed in ice water until no more alc. is evolved, 0.3 cc. of the distillate is shaken with 0.7 cc. of a mixt. of 80 cc. of abs. alc. and 20 cc. of H_2O, and a soln. of 0.1 g. of $NH_2OH.HCl$ in 3 cc. of water is added. The mixt. is shaken for 3 min. at room temp., 0.4 g. of absorbent charcoal is added and the mixt. is shaken and filtered through a small dry paper into a 100-cc. round-bottomed flask. Five cc. of a freshly prepd. soln. of 0.5 g. of piperonal in 100 cc. of abs. alc. is added,

followed by the slow addn. of 20 cc. of H_2SO_4, sp. gr. 1.84. The mixt. is shaken and placed on the water bath for 5 min. in a large test tube; a red color indicates the presence of isopropyl alc., and a green-brown color its absence. If 30 cc. of 30% AcOH is added, a stable rose-red color is a pos. reaction; a brown color indicates the presence of a small quantity of the alc.; a colorless soln. or weak red tinge stable for a min. and turning yellow-gray or colorless shows a definite reaction. The sensitiveness of the reaction is 1–2% for most substances but is delicate to 0.1% with liniments. In the latter, CH_2O, if present, must be removed before distn. by heating the sample with 5 cc. of NaOH soln., sp. gr. 1.125, under a reflux condenser for 1 hr. Concns. of acetone less than 20% have no harmful effect on the reaction. C. R. FELLERS

Colorimetric determination of the tyrosine and tryptophan contents of various crude protein concentrates. WM. D. MCFARLANE AND HUGH L. FULMER. *Biochem. J.* **24**, 1601–10(1930).—The detns. were based on the method developed by Folin and Ciocalteu (*C. A.* **21**, 3210). The tyrosine (ty.) and tryptophan (tr.) contents in one series of expts. were as follows:

	Ty.%	Tr.%
Caseinogen	7.59	1.54
Buttermilk powder	6.36	1.25
Meat meal	3.02	0.95
Tankage	2.42	0.88
Cod-liver meal	..	0.77
Fish meal	2.92	1.38

BENJAMIN HARROW

The separation of Be and Al oxides (TRAVERS, SCHNOUTKA) **6.** Technic of extracting liquids that form emulsions (WEINBERGER) **2.** Apparatus for electrical tests to identify various materials (U. S. pat. 1,793,970) **4.**

MERCK, E.: **Prüfung der chemischen Reagentien auf Reinheit.** 4th ed. Darmstadt: Merck. 401 pp.

Determining monatomic substances in gases, particularly mercury vapor in air. SIEMENS & HALSKE A.-G. (Otto Krenzien, inventor). Ger. 517,480, Sept. 13, 1928. The method depends on the detn. of the intensity of the resonance effect produced when a beam of light, the spectrum of which includes a "resonance line" of the spectrum of the element to be estimated, is directed through the gas in which the element is to be detd. and then into a vessel also contg. the vapor of the element.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

The formation of calcite crystals by slow precipitation of calcium salts in water by ammonia. J. HENRION. *Ann. soc. geol. Belg.* **53**, B40–1(1929).—A flask of tap water connected by an overhead glass tube to a flask of concd. NH_3 pptd. calcite, identified petrographically, on 4 months' standing. R. H. EWELL

The precipitation of calcium carbonate in dilute solutions. F. CORIN. *Ann. soc. geol. Belg.* **53**, B64–6(1930).—Referring to Henrion's paper (preceding abstr.), C states the present status of the subject, and cites the work of several earlier investigators. R. H. EWELL

The deposit of cerite in Kystym district. V. ZILBERMINTZ. *Trans. Inst. Econ. Mineral* (Moscow) No. **44**, 41–2; cf. *C. A.* **24**, 4243.—Assocd. with parisite there has been found another mineral, differing in all its properties but closely connected genetically. It contains about 19% SiO_2, 11% CaO and 64% Ce, La and "Di" oxides. It approaches cerite in optical properties and compn. but is purer than Swedish cerite. H. C. PARISH

Radioactive mineral found in Japan. SATOYASU IIMORI, JUN YOSHIMURA AND SHIN HATA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, No. 285, 83–8(1931). A radioactive mineral has been found in the Bijozan Range, in black prismatic crystals about 6–7 mm. long, with a resinous luster and a hardness of 5.5. The powder and the streak are brown. It is easily decomposed by HCl, leaving a white flocculent residue

It is a new species belonging to the epidote group, and the name *nagatelite* is suggested. Its radioactivity is thought to be due to a small quantity of Th. An intensively radioactive mineral was found in a biotite crystal. It gave a qual. test for U. Laterite and lateric clays were also found. Analyses of some of the minerals are given.
L. D. ROBERTS

A variety of uranotile from Chinkolobwe (Katanga). J. THOREAU. *Ann. soc. geol. Belg.* **53,** B60–4(1930).—A sample of pitchblende was encrusted with a thin layer of yellow radiating needles with black opaque inclusions, weakly dichroic, with parallel extinction, + elongation, $n_g = 1.703$, $n_p = 1.632$. The d. is greater than 3.3. Analysis gave: volatile matter (H_2O) 15.4, insol. matter (SiO_2) 6.8, UO_3 73.1, CaO 7.4%. This corresponds roughly to $SiO_2 \cdot 2UO_3 \cdot CaO \cdot 6H_2O$. The mineral dissolves in cold concd. HCl with evolution of a gas, and if heated the black inclusions also dissolve. The black mineral may be uraninite. There is also another yellow, fibrous mineral on the pitchblende with somewhat different properties (n_g less than 1.676), which may be another variety of uranotile.
R. H. EWELL

Sorption of gas by minerals. II. Laumontite. JITSUSABURO SAMESHIMA. *Bull. Chem. Soc. Japan* **5,** 303–10(1930).—Laumontite ($CaAl_2Si_4O_{12}\ 4H_2O$) sorbs NH_3, but not CO_2. The sorption data are tabulated and presented in curves. The dryness of the mineral has an important influence. NH_3 combines chemically with the dehydrated mineral.
ALBERT L. HENNE

The presence of apatite in the Upper Cambrian rocks of Neuville. Note on the optical study of weakly birefringent minerals. F. CORIN. *Ann. soc. geol. Belg.* **53,** B66–8(1930).—After considerable difficulty, C identified apatite as an accessory constituent of these rocks. The birefringence is only 0.0015.
R. H. EWELL

Contribution to the mineralogy of the coal fields. M. BELLIERE. *Ann. soc. geol. Belg.* **53,** B125–39(1930).—The mode of occurrence in various coal-mining regions of Belgium is described for the following minerals: S, sal-ammonite, ankerite, quartz, pholerite, pyrite, chalcopyrite, sphalerite, galena, calcite, dolomite, gypsum and aragonite. Crystallographic data and chem. analyses are given.
R. H. EWELL

Petrographical description of the Sadon mine. E. A. KUZNETZOV. *Trans. Inst. Econ. Mineral* (Moscow) No. **46,** 3–53(1930). The aplite veins are adapted to a transverse system of cracks, which are parallel to a more recent thrust. The same direction was followed by keratophyres at a later period. After a long period of rest accompanied by the destruction of granite and deposition upon it of sedimentary rocks, new movements produced new cleavages, along which flowed the overlying keratophyres. Then, after another period of relative rest, a new fracture occurred in the same region, where granite, porphyry and sedimentary formations were caught by the movement and ground up. Simultaneously ore-bearing solns. rose from their original depth reservoir. The granite was crystd. under the influence of its own gas phase. Apparently the hydrothermal solns. were rather hot at first. Later they cooled and the main manifestation of their force is to be seen in silication, sericitization, chloritization and carbonatization of adjacent rocks.
H. C. PARISH

Mineralogy of the Sadon ore vein. E. E. ZAKHAROV. *Trans. Inst. Econ. Mineral* (Moscow) No. **46,** 54–152(in English) 153–4(1930).—The Sadon deposit of Pb-Zn ore showed galena, sphalerite, pyrite, chalcopyrite, pyrrhotite, arsenopyrite and molybdenite, of the gang minerals quartz, carbonates, chlorite, muscovite and a mineral of the gummite series. A series of the minerals smithsonite, cerussite, malachite, azurite, gypsum and Pb oxide has also been discovered. Z. notes: breccia structures, imbricated and banded structures, a thick network of ore-bearing veinlets, a thick ore-inclusion and structureless formations.
H. C. PARISH

Magnesite: its application in assaying. R. J. B KETHEL. *J. Chem. Met. Mining Soc. S. Africa* **31,** 172–5(1931); cf. *C. A.* **24,** 5256.—Discussion.
ALDEN H. EMERY

Asbestos deposits in the Union. A. L. HALL. *S. African Mining Eng. J.* **41,** II. 423–4(1930), 487–8(1931).—The Union of South Africa contains asbestos deposits of very considerable extent. It is the leading crocidolite producer. The following fiber varieties occur in the Union: amosite, crocidolite, chrysotile, anthophyllite, tremolite. The occurrences of each are described.
ALDEN H. EMERY

Petrology of chrysotile asbestos deposits of the Krasno-Uralsky asbestos mine in the Ural Mountains. V. V. ARSHINOV AND B. YA. MERENKOV. *Trans. Inst. Econ. Mineral* (Moscow) No. **45,** 1–83(1930).—The asbestos is graded according to fiber length as follows: grade I about 16 mm.; grade II, 12 mm.; III, 8.5 mm.; IV, 4 to 2 mm.; VI, 2 to 0.5 mm. It is believed that the serpentines of this region have been derived from saxonites under the simple influence of water. Other basic rocks encountered in small quantities are schlieren of pyroxenite, a mono-mineral rock formed by diopside.

The serpentinization of saxonites is developed along the fissures as ribbons of serpentine. As this process goes on, the grain size diminishes until the whole rock is altered into serpentine. The characteristic types of asbestos ribboning are represented by the following varieties: (1) bordered asbestos, (2) fine asbestos veinlets branching, (3) fine asbestos parallel sets. A. believes all of these rocks to be products of the differentiation of diorite intrusive bodies. The absence of granite pegmatite dikes is characteristic for the asbestos deposits of the Krasno-Uralsky mine. H. C. PARISH

A new deposit of plastic clay. L. NYS. *Ann. soc. geol. Belg.* **53,** B77–8(1930).—The deposit is at Grosses Pierres. Analysis gives: SiO_2 73.08, Al_2O_3 19.97, Fe_2O_3 1.78, CaO 0.10, MgO 0.06, loss on heating 4.30%. There are inclusions of yellow sand and small amts. of andalusite, zircon, magnetite and tourmaline. R. H. EWELL

Studies on the moisture adsorbed by the Kanbara clay. HAJIME ISOBE. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14,** 229–74(1930)(in English).—In certain deposits of Kanbara clay the upper layers are acid, the middle layer is neutral and the lower alk. Neutral clay can be prepd. from either the acid or the alk. clay by washing with distd. water. Acid and alk. clays show different vapor-pressure curves, but the curves of the natural neutral clay, clay artificially neutralized with acids or alkalies and clay made neutral by washing with distd. water, have practically the same characteristics at the same temp. The water adsorbed by special capillary action ranges from 20 to 35%, while that due to true adsorption of the surface of the clay is about 2 to 18%. On the basis of x-ray studies the formula $[Al(SiO_4SiO_2)_3]MgH_2O$ is advanced for the clay. K. D. JACOB

The translucent and opaque diamonds of the Bushmaie deposits. EDMOND POLINARD. *Ann. soc. geol. Belg.; Publ. rel. au Congo Belge* **52,** C179–218(1929); **The transparent diamonds of the Bushmaie deposits.** *Ibid* **53,** C1–45(1930).—Complete and detailed crystallographic data are given. R. H. EWELL

The igneous rocks of the Helle (Haute Fagnes). PAUL RONCHESNE. *Ann. soc. geol. Belg.* **54,** B35–43(1930).—Petrographic analysis shows these rocks, formerly classed as granites, to be quartziferous diorites, because they contain about 30% of anorthite in the plagioclase and a small amount of orthoclase. Analysis gives: SiO_2 70.06, Al_2O_3 14.86, Fe_2O_3 1.64, FeO 0.63, FeS_2 1.28, MnO 0.06, CaO 3.45, MgO 1.02, K_2O 2.06, Na_2O 4.83%. Accessory minerals include biotite, chlorite, magnetite, epidote, apatite, zircon, sericite, kaolinite and sulfides. R. H. EWELL

The plagioclases of the igneous rocks of the Helle. P. MICHOT. *Ann. soc. geol Belg.* **54,** B44–8(1930); cf. preceding abstr.—M. discusses the mutual soly. of orthoclase, albite and anorthite to explain the absence of separate crystals of orthoclase, when its presence is shown by chem. analysis. The zoning of the plagioclases is explained by the effect of irregularly varying pressures on the temp.-compn. diagram of the system. R. H. EWELL

The pegmatites of the sodalitic syenite of the Island Rouma (archipelago of Los, French Guinea). Description of a new mineral (serandite) found there. A. LACROIX *Compt. rend.* **192,** 189–94(1931).—The island is very rich in feldspathoid syenite. Mineral constituents of the pegmatites are described, and mineralogical characteristics of normal syenite are compared with those of the pegmatites. The new mineral called serandite is described in detail, and chemical analysis given: SiO_2 48.72, Al_2O_3 0.29, Fe_2O_3 0.03, FeO 1.33, MnO 28.99, MgO 0.06, CaO 10.42, Na_2O 7.38, K_2O 0.26, H_2O+ 2.67, H_2O- 0.11%, corresponding to SiO_2 $(MnO_2.CaO).(Na_2O.K_2O).H_2O$. A somewhat similar manganese-bearing pectolite from Magnet Cove, Ark., is discussed, but the Mn is in smaller quantities, and d. and optical properties are different from those of the new mineral. ALICE W. EPPERSON

The alkaline rocks of the southern part of Kystym district, Ural. E. A. KUZNETZOV. *Trans. Inst. Econ. Mineral* (Moscow) No. **48,** 1–89(1930).—This area is formed of granite-gneisses, syenites and miascites. In the granite-gneisses are bands of amphibolites, quartzites and garnet-mica gneisses. Analyses of the miascites are given. On the mountain Sobachy all the miascite bands are edged by alk. syenites forming the reaction zones of miascite and granite-gneisses. The western dikes of miascites are more or less sharply sepd. from the country rocks, the latter being altered into syenite-gneisses with aegirite-augite and biotite. As against the Eastern band the miascites become fine grained in contact and at some places contain considerable porphyritic inclusions and albite or elaeolite up to 5 cm. In other respects all miascites are similar. H. C. PARISH

Mariupolite and its related rocks. J. MOROZEWICZ. *Prace Polsk. Inst. Geol.* **2,**

217–350(1929); *Tschermak's Mineral. Petrog. Mitt.* **40**, 335–436(1930).—Mariupolite, from Ukraine, is an extreme member of the nepheline-syenite series. It consists of albite, nepheline and aegirine, with sometimes lepidomelane, sodalite or cancrinite, and accessory magnetite, beckelite and pyrochlore. The order of intrusion of this and the assocd. rocks was that of increasing bacisity:

	Mean d.	Mean SiO_2 (mol.-%).
1. Upper biotite-granite	2.632	80.0
2. Diallage- and amphibole- granite	2 678	74.4
3. Alkali-syenites	2 699	70 5
4. Mariupolites	2.712	63.9
5. Foyaites	2.718	60.6
6. Wehrlite	3 359	46.2

Many chem. analyses are given of these rocks and their constituent minerals, and the relations are discussed in detail. B. C. A.

Origin of certain Pre-Cambrian amphibolites in Agder (Southern Norway). TOM F. W. BARTH. *Norsk Geol. Tids.* **11**, 219–31(1930).—Pre-Cambrian amphibolites found in Agder have the same 3 modes of origin as those found by Adams (*Compt. rend. Congr. Géol. Int. Stockholm* **1910**, 536–72) for amphibolites from Haliburton and Bancroft areas (*Memoir* **6**, *Can. Geol. Survey*, **1910**). Comparative compns. are shown. A para-amphibolite formed by metamorphic action of granitic magma or "ichor" on impure calcareous sediment embedded in the magma is described. A map of a small area of Pre-Cambrian rocks in which amphibolites originated by alteration of limestones by the action of granitic "ichor" is shown. The same mechanism produced an amphibolite which formed a basic schlieren in the anorthosite on the eastern slope of Mt. Pokamoonshine in the Adirondacks. Detailed data on different amphibolites are presented. Actinolitic hornblende occurs in Norwegian amphibolites formed by alteration of pure limestones; other types contain common hornblende. A theory of formation is discussed. E. M. SYMMES

Structure and form of fresh-water limestones. E. ROZENŠTEINS. *Acta Univ. Latviensis Kim. Fakultat. Serija* **1**, Fas. 1 Burtnica; (in German 13–24) (in Lettish 25–7(1929)).—The compact limestones consist of microcryst. (0.01–0.2 mm.) or mesocryst. (0.25–0.07 mm.) calcite aggregates in rosette or druse forms. The medium compact limestones are of crypto- and pelitomorphous aggregates (0.003–0.005 mm.) and often the interspaces are filled with secondary crystals. Around thin plant fibers there forms a strong crust which tends to form in layers. The gypsum content may range from 1.24 to 4.12% and may be found in limestones deposited from gypsum-free water, on account of the oxidation of pyrite. Silica was as high as 13.92%. A. N. H.

Structure of weather-resisting rocks. A. L. W. E. VAN DER VEEN. *1st Communications New Intern. Assoc. for Testing of Materials B*, 10–2(1930).—Fossilization (cementation) of a sediment is made by solns. circulating in its interstices. The microscope reveals the mineralogical compn. of the sediment and the nature of its cement. The chem. analysis of a weather-resisting rock may suggest that something is wrong within, whereas the microscope reveals that the dangerous atoms are locked up in most resisting minerals. The relation between genesis and weather resistance of some sandstones and marbles is described. E. J. C.

Mineralogical study of the soil of the Vercelli district. E. REPOSSI. *Atti accad. sci. Torino Classe sci. fiz., mat. e naturali* **64**, 335–58(1929). B. C. A.

The ceramic industry of Ontario (MONTGOMERY) **19**. Au—its geographic distribution and geological occurrence (BELL) **9**. Phase equilibrium in binary systems with continuous mixed crystals (KORDES) **2**. Gravity separation (EMMONS) **2**. The geochemistry of the Ti group (VON HEVESY) **2**.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, H. W. GILLETT AND RICHARD RIMBACH

Present status of the dressing of bituminous copper ores. A. GÖTTE. *Metall u. Erz* **28**, 73–5(1931).—The most notable deposits of bituminous Cu ores in Germany are at Niedermansberg and Mansfeld. A discussion of dressing methods used for these ores is given. The bituminous content in no way interferes with the flotation processes. H. STOERTZ

Investigation of ore dressing machines with the help of yield calculations. W. LUYKEN AND L. KRAEBER. *Metall u. Erz* **28**, 49–55(1931).—A study of operating conditions at the "Ant" mine in Siegerland by comparison of the yields obtained from a dust settling machine and a Hercules hearth. The particle range is 22–2.5 mm. for the first machine and 2.5–0 for the second. H. STOERTZ

Effect of particle size on flotation. A. M. GAUDIN, JOHN O. GROH AND H. B. HENDERSON. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **414**, 3–23(1931).—A study is made to det. what effect particle size has on floatability. One method of study was on the samples of the final products of several mills and in the other mixts. of pure minerals were ground to different degrees of fineness and floated. In both cases the products were sized and analyzed. Conclusions: The results obtained by the 2 methods are in agreement. The usual notion about the relative ease of flotation of very fine particles does not agree with the facts. There is a time sequence of flotation with regard to size, the medium coarse particles floating first. No successful method of floating extremely fine pulps has been found. Recovery is optimum in a well-defined size range. Selection is optimum in another well-defined range. The bulk of the pulp is in the range of 100–800 mesh. Thirteen figures and 5 tables are shown. Data from lab. and practice agree closely. W. H. BOYNTON

Experimental flotation of oxidized silver ores. H. S. GIESER. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **401**, 9 pp.(1931).—Because of the other uses the no. of org. S compds. available for flotation is limited. Benzyl mercaptan and benzyl sulfide and disulfide show interesting results. Thioureas leave high tailings. When the diethylphenyl- and di-*o*-tolyl-thioureas are used the froth is white and barren. Mercaptobenzothiazole is of some value with a number of oxidized precious-metal ores. Thioacetanilide gives fair results, while thiobenzanilide is better. Reagent soly. is an important factor in flotation. H. C. PARISH

Flotation of minor gold in large-scale copper concentrators. E. S. LEAVER AND J. A. WOOLF. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **410**, 32 pp.(1931).—CaO is an active depressant for free Au during flotation if the alky. of the soln. circuit is $p_H = 10$ or above. A reaction of p_H 7.5 to 10 is best. In the flotation of base-metal ores contg Au as a by-product careful regulation of CaO, avoiding excess, will increase Au recovery. If pyrite in the ore is crushed fine enough to free the Au, most of the pyrite may be depressed by low CaO alky. in the flotation circuit and a high percentage of the Au floated with the Cu sulfides. Ores with a low ratio of pyrite to CuS and contg. under $1 in free Au per ton gave, by control of the flotation circuit assuring low alky., 25% Cu concentrates contg. more than 90% of the Cu and more than 80% of the Au. Ores high in pyrite and lean in Cu sulfides and Au as a nominal by-product, offer low-grade concentrates unless the percentage of Au recovery is sacrificed. In the flotation of oxidized base-metal ores in which a sulfidizing reagent is used, Na_2S gives a much higher Au recovery than CaS or Ca polysulfide; Ca salts depress Au. H. C. PARISH

Investigation on the influence of the iron content of zinc blendes on their floatability. LUDWIG KRAEBER. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* **12**, 343–52 (1930).—Flotation tests were made on blendes in a mechanically agitated cell and in a pneumatic cell. It was found that each sample of blende gave a definite p_H to the water regardless of whether the water was originally slightly alk. or acid, the value being lower for blendes of high Fe content. The max. recovery was obtained with a p_H between 6 and 7, and it appeared that the optimum p_H was lower for high Fe content. Very small quantities of CuS speeded up the rate of recovery. The quantities of KCN and $ZnSO_4$ necessary to hold down the Fe differed widely for different ores but bore no simple relation to the Fe content. Conclusion: The presence of foreign materials as well as the pretreatment is of more significance than the Fe content in affecting flotability. H. C. DUUS

Quinquennial review of the mineral production of India for the years 1924 to 1928. *Records Geol. Survey India* **64**(1930).—**Gold.** G. DEP. COTTER. *Ibid* 92–106.—Indian Au occurs both in veins and as alluvial deposits. Individual deposits are described Production has fallen steadily since 1915. **Lead.** G. VERNON HOBSON. *Ibid* 154–66.—Near Bawdwin ore-bearing solns. have ascended through crushed rhyolitic tuffs, flows and breccias metasomatically replacing materials in the tuff and leaving sulfides. The ore is an intimate mixt. of Ag-bearing galena and sphalerite and in many places also chalcopyrite. Production for 1924–28 averaged about 60,000 tons of Pb and 5¾ million oz. Ag. **Manganese.** L. L. FERNOR. *Ibid* 172–233.—Indian Mn occurs chiefly in metamorphosed manganiferous sediments contg. spessartite and rhodonite. Typical ores contain braunite and psilomelane. Ores are also found in assocn. with cryst. limestone contg. piedmontite. Other minerals found are holland-

ite, vredenbrugite, sitaparite and rarely pyrolusite. The high-grade ores contain Mn 48–54, Fe 4–8 and SiO_2 6–9%. World production, analyses of ores, manuf. of ferromanganese in India, various economic considerations, etc., are discussed. India is the world's leading producer. **Silver.** G. VERNON HOBSON. *Ibid* 293–8.—No ores are mined primarily for Ag in India. Over 99% of the production is a by-product from Pb, the remainder from Au. The government Ag refinery is described in detail. **Tin.** J. COGGIN BROWN. *Ibid* 298–305.—Almost all India's Sn production comes from Burma cassiterite, the occurrence of which is described in the section on tungsten. **Tungsten.** J. COGGIN BROWN. *Ibid* 305–10.—Wolfram and cassiterite occur in quartz veins closely assocd. with a biotite boss-granite intruded into a series of slates, shales, argillites and agglomerates with greatly subordinate quartzites, limestones and conglomerates. The veins fill fissures. The mineral associates of wolfram are not the same in different deposits. The various assocd. minerals are beryl, tourmaline, mica, fluorite, molybdenite, pyrrhotite, galena, sphalerite, arsenopyrite, Bi, bismuthinite and topaz. The vein formation appears to be a direct sequence of processes of differentiation influenced by local conditions. **Zinc.** G. VERNON HOBSON. *Ibid* 310–2.—Sphalerite occurs with galena at the Bawdwin mine. The industry is growing.

ALDEN H. EMERY

The composition of Finnish ores. GUST. A. AARTOVAARA. *Ylipainos Tekn. Aikakauslehti* (Reprint) **10**, 1–9(1927).—Analyses are given of sulfide and oxide ores.

J. RYSELIN

The use of Greek nickel ores in Germany. E. REITLER. *Metallbörse* **20**, 2273–4 (1930).—Before the war the German nickel works used New Caledonian ore and some American oxide. Attempts have been made to use Greek nickel ores from the Laurion Mountains. The compn. of these ores is, on the dry ore: NiO 6.62, CoO 0.15, Fe_2O_3 40.01, SiO_2 28.86, Al_2O_3 14.64, As_2O_3 0.04% and minor quantities of CuO, CaO, MgO and Cr_2O_3. The smelting of these ores is complicated by the presence of so much alumina, which give very viscous slags. It is very doubtful if these ores can be successfully used.

R. S. DEAN

Iron ore on Canyon Creek, Fort Apache Indian Reservation, Arizona. ERNEST F BURCHARD. U. S. Geol. Survey, *Bull.* **821-C**, 51–75(1931). E. H.

Rationalization of the fusion of lead minerals. N. C. KYRIACOU. *Génie Civil* **98**, 184–9(1931).—Insufficient prepn. of the mixing bed and imperfect combustion raise the consumption of coke. The metal should be dense, free of S, in the form of the silicate, perfectly clinkerized and free of dust. The most suitable size of granule is 20 mm. in diam. A rotary furnace for preliminary roasting feeds its charge directly to the shaft furnace. The use of a water jacket and of a forehearth reduces Pb losses.

ANN NICHOLSON HIRD

Treatment of low-grade gold ores at West Rand (South Africa). JEAN FULOP. *Génie Civil* **98**, 153–8(1931).—Modern equipment has raised the Au recovered by the cyanide process from 49.78 to 61.93%. The Au in the tailings is lowered from 0.316 to 0.256 pennyweight per ton.

ANN NICHOLSON HIRD

Origin of flour gold in black sands. A. E. KELLOGG. *Mining J.* (Arizona) **14**, 3 4, 49–50(1931).—Flour Au may float over riffles, adhere to black sand or magnetic Fe or refuse to amalgamate. Flour Au may have been originally minutely dispersed through rocks, run into soln. with quartz in vein fissures, wrapped up within or chemically combined with other Au ores or may have been formed by attrition by waves. An example of such grinding is in the very ancient Siskiyou Island. No reliable means of recovering flour Au is known.

E. M SYMMES

Gold—its geographical distribution and geological occurrence. J. MACKINTOSH BELL. *Canadian Mining J.* **52**, 246–51(1931).—An address is given which covers the world's gold fields. It seems probable that the annual production of Au will decrease 20–25% during the next decade.

W. H. BOYNTON

Mining and mill in the Vermont copper district. C. S. ANDERSON. *Eng. Mining J.* **131**, 208–10(1931).—Mining of the cupriferous pyrrhotite deposits of Vermont is outlined. The Cu content varies between 0.5 and 20% with an av. of about 3%. A flowsheet is shown for the Elizabeth-Foster-Cleveland mill of the National Copper Corp.

W. H. BOYNTON

Milling methods and costs at the Spring Hill concentrator of the Montana Mines Corporation, Helena, Montana. L. A. GRANT. Bur. Mines, *Information Circ.* **6411**, 8 pp.(1931).—The ore, Au (10–15% native) assocd. with pyrite, arsenopyrite and Bi, occurs disseminated through diorite along a limestone contact. Barren pyrrhotite, the most plentiful sulfide, floats with the Au-bearing sulfides. Costs per ton of ore concd. for 1929–30 were crushing and conveying $0.162, grinding $0.290, flotation

$0.258, tailings disposal $0.052, H_2O $0.012, repairs $0.233 and total $1.007.
ALDEN H. EMERY

Milling methods and costs at the lead-zinc concentrator of the Treadwell Yukon Company, Limited, at Tybo, Nevada. W. H. BLACKBURN. Bur. Mines, *Information Circ.* 6430, 14 pp.(1931).—The ores are complex and contain Pb, Zn, Fe, Ag and Au. Most of the Ag is assocd. with galena. Sphalerite and pyrite are also argentiferous. Pb concentrates average 90.43 oz. Ag per ton, 62.75% Pb and 3.50% Zn. Zn concentrates average 13.65 oz. Ag per ton, 2.71% Pb and 46.57% Zn. Costs for March, 1930, were in cents per ton of ore treated: sorting 1.8, crushing 7.9, grinding and classification 44.5, flotation 50.2, filtering 2.1, general 21.7 and total $1.282. Pb recovery is 74%, Zn 79%, Ag 75%. Detailed metallurgical data are given. ALDEN H. EMERY

The absorption of gold in tube mills. H. A. WHITE. *J. Chem. Met. Mining Soc. S. Africa* 31, 161–71(1930).—Though concn. upon the surfaces of pebbles and tube linings is a real effect, it does not account for more than a minor portion of the total Au locked up in the tube. The remainder is held in the numerous joints in the linings, between the lining and the shell and in other crevices. ALDEN H. EMERY

Amalgamation practice at Porcupine United Gold Mines, Ltd., Timmins, Ontario. RONALD A. VARY. Bur. Mines, *Information Circ.* 6433, 5 pp.(1931).—The ore consists of quartz with fine stringers of mineralized basaltic schist, or of banded quartz schist, or of stringers of quartz in schist, accompanied by pyrite and often contg. visible Au. It is amalgamated in a 25-ton pilot mill. Costs per ton of ore treated are crushing $0.384, grinding $0.771, classifying, screening, conveying and refining $0.626, miscellaneous $0.070 and total $1.851. ALDEN H. EMERY

Historical evolution of Lower Harz smelting methods. ROSENHAINER. *Metall u. Erz* 28, 75–85(1931). H. STOERTZ

The rationalization of zinc smelting in horizontal retorts. H. BEERMANN. *Metall börse* 20, 2385–6, 2441–2(1930).—The slowness of the reaction is due to the inability to carry it on at a very high temp. since the reaction zone proceeds inward concentrically from the retort walls and consequently the Zn reduction reaction is going on at a gradually decreasing temp. and hence rate. From these considerations B. concludes that a small quantity of some gas which would not interfere with condensation could be profitably introduced into the retort to equalize the temp. somewhat. No test has been made of the idea. R. S. DEAN

The reaction between magnetite and ferrous sulfide. II. F. S. WARTMAN AND G. L. OLDRIGHT. Bur. Mines, *Rept. of Investigations* 3072, 10 pp.(1931); cf. *C. A* 23, 1374.—SiO_2 and MgO accelerate, whereas CaO, Al_2O_3 and Cu_2S hinder, the reduction of magnetite by FeS. Orthoclase, anorthite, albite and kaolin also accelerate the reaction. ALDEN H. EMERY

Nickel slagging in copper refining with the formation of ferrites. W. STAHL. *Metall u. Erz* 28, 55–6(1931).—In the presence of Fe it is comparatively easy to remove Ni from Cu by slagging it out as ferrites ($NiFe_2O_4$ and $NiFeO_4$). The residual Cu still has a Ni content of 0.10–0.15%, which cannot be removed in this manner. H. S.

Suggested improvements in fire refining of copper. H. H. ALEXANDER. *Eng. Mining J.* 131, 226–9(1931).—An outline is given of methods incorporated in U. S. Patents 1,687,277(*C. A.* 22, 4450), 1,756,967 (*C. A.* 24, 3207) and 1,776,826 (*C. A* 24, 5711). Means of removing impurities by oxidation, the deoxidation of Cu and improved melting practice as tried out in the lab. and in furnaces of com. size are pointed out. Melting and refining simultaneously result in: low initial cost of equipment, lower slag production, few repairs, low operating cost and a better product.
W. H. BOYNTON

The zinc industry in Belgium. V. FIRKET. *Bull. soc. belg. ing. ind.* 10, 799–844 (1930). E. H.

Photoelectric control for soaking-pit covers. R. M. BAYLE. *Elec. World* 97, 409 (1931). C. G. F.

Fluorspar in the open-hearth slag. H. L. GEIGER. *Blast Furnace Steel Plant* 19, 412–4(1931).—A survey of the work of prominent metallurgists to help to make clear the much discussed function of fluorspar in the thinning of slag. Basic open-hearth tapping slags do not contain F. F is probably lost as volatile SiF_4, and a little as a volatile F-S compd. (In the basic elec. process very little F is lost; however, very little SiO_2 is present.) The action of fluorspar is probably to decrease the SiO_2 in the slag by the formation and loss of SiF_4. In order to establish equil. FeO and Fe_2O_3 from the bath replace the lost SiO_2. It is generally agreed that these metallic oxides increase fluidity. If this analysis is correct, then Fe oxide is the actual thinning agent.
A. W. HOLMES

The economic situation of non-ferrous metallurgy. LÉON GUILLET. *Génie Civil* **98**, 81–5(1931).—International statistics are given on the production, export and import of Cu, Pb, Zn, Sn, Sb, Ni, Al, Hg, Ag, Pt and Au from 1870 to 1928. A. N. H.

X-rays in the foundry trade. R. BERTHOLD. *Giesserei-Ztg.* **26**, 642–4(1929).—The economic value of the use of x-rays in the foundry is discussed with particular reference to light metal castings. MALCOLM DOLE

X-ray technic in the foundry. WALTER B. BARTELS. *Giesserei-Ztg.* **26**, 632–4 (1929).—A discussion of the technic, costs and profits of the use of x-rays in the foundry. MALCOLM DOLE

Rosin in core oil. WERNER G. SMITH. *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 839–41(1930).—The compn. of core oils and their use in the foundry are discussed. During baking of the core much of the core oil is lost by volatilization, leaving a porous but strong material which is free from gas-producing substances. Rosin imparts tensile strength to the oil film and prevents excessive absorption of the oil by sands contg. loam. The medium grades of rosin are commonly used for this purpose. S. suggests improvements in the packaging and shipping of rosin. H. K. SALZBERG

The influence of colloidal ferric hydroxide upon the properties of molding sand. ETUJI TAKAHASI. *Kinzoku-No-Kenkyu (J. for Study of Metals)* **7**, 552–62(1930).—A difficulty connected with synthetic molding sands consists in the lack of durability: that is, fine clayey substance is liable to sep. from the sand. In a study of the action of electrolytes and $Fe(OH)_3$ sol upon clay substance in molding sand, T. found that the addn. of colloidal $Fe(OH)_3$ increases either the plasticity or the gas permeability according to ramming conditions. The increase in gas permeability seems to be due to the coagulation of clayey particles. It prevents the separation of bonding substance from the sand. Various applications of colloidal $Fe(OH)_3$ for making synthetic sands were also studied. M. KURODA

Influence of siliceous matters upon the reduction of magnetic sands. KEIZO IWASE AND MASAJI FUKUSHIMA. *Kinzoku-No-Kenkyu (J. for Study of Metals)* **7**, 524–34(1930).—The influence of siliceous matter such as tailings, sea sand, pptd. silica and alumina upon the rate of reduction of magnetic sands has been detd. at temps. between 900° and 1150°. At lower temps. their influence is small because no sintering occurs but at higher temps. the semi-reduced product FeO from the hematite in the tailings and other substances combine with silica forming semi-fused substances and retard considerably the rate of reduction. M. KURODA

The manufacture and properties of malleable castings. J. K. SMITHSON. *Foundry Trade J.* **44**, 110–12(1931).—A description. H. C. PARISH

New methods of producing quality gray cast iron, hard cast iron and tempered cast iron in cupola furnaces. LAMLA. *Giesserei-Ztg.* **27**, 621–3(1930).—A general discussion. H. C. DUUS

Low-carbon, malleable cast iron from cupola furnaces. W. VALENTIN. *Giesserei-Ztg.* **27**, 617–22(1930).—A general discussion. H. C. DUUS

Advantages of fine-grained iron over coarse-grained iron for the production of high-grade castings. R. SCHMITT. *Z. ges. Giessereipraxis* **51**, 25–8(1930); *Chimie & industrie* **25**, 81(1931).—By the use of fine-grained iron instead of hematite iron, castings with identical C, Si, Mn, P and S contents but of finer grain were obtained; the tensile strength increased from 23 to 26 kg. per sq. mm., the Brinel hardness was unchanged, and the mech. properties of the castings were improved in spite of an increase in the graphitic C content. The effects of the size of the grains were evaluated quantitatively, and variations in the mech. properties resulting from the metallographic tests confirmed the following mechanism: When fine-grained iron is used, the small graphite lamellas are completely dissolved in the iron; this results in a state of high dispersion of the graphite in the castings, which in turn produces a fine-grained structure on cooling. If coarse-grained iron is used, the graphite lamellas are not uniformly distributed; this leads to irregularities in structure on cooling. A. PAPINEAU-COUTURE

Sulfur in cast iron. H. H. EBERT. *Zentral Europ. Giesserei-Ztg.* **3**, 3–4(1930).—Methods of desulfurization are discussed. B. C. A.

Cast chromium steels in wider use. H. D. PHILLIPS. *Steel* **88**, No. 2, 39–43 (1931).—A discussion of production processes, properties and uses of chromium steels. LESLIE B. BRAGG

Overcoming certain operating troubles in making open-hearth steel. T. N. ARMSTRONG. *Iron Age* **127**, 864–7(1931).—The advantages incident to the use of burnt lime instead of raw limestone in basic open-hearth steel charges are discussed, as well as the methods of overcoming a no. of common troubles encountered in open-hearth

operation, particularly those connected with the use of Southern grades of pig Fe. DOWNS SCHAAF

The system: iron-carbon. EUGÈNE L. DUPUY. *Rev. métal.* **27**, 686–92(1930).—A review. H. S. v. KLOOSTER

Manufacture of ferro-silicon. ROY P. HUDSON. *Blast Furnace Steel Plant* **19**, 399–401(1931).—The chief district for producing ferro-Si is Jackson County, Ohio. Originally, lean ores of the district were used, but these have been supplanted by Lake Superior ores. The blast furnace can produce metal contg. 18% Si, but most grades average 6–15% Si. Ferro-Si is notably low in S on account of the high temp. of formation and large vol. of slag produced. Bituminous coal is used in admixt. with coke to decrease the fuel cost. Because of the high temp. required to reduce a large quantity of silica to Si, the heat should be concd. in a small area; therefore, the boshes and hearths are always smaller. In the manuf. of high-Si iron the evidence indicates that when alumina is lower than 17% it acts as an acid and above this it acts as a base. But as it rarely exceeds that amt., alumina is always considered an acid. A. W. HOLMES

Open-hearth combustion. W. P. CHANDLER, JR. *Proc. Eng. Soc. West. Penn.* **46**, 241–63(1930).—See *C. A.* **24**, 5265. H. C. DUUS

Recent advances in metallography. I. L. HAUGHTON. *1st Communications New Intern. Assoc. for Testing of Materials A*, 316–9(1930).—A review of the advances in the methods of thermal and microscopic analysis of alloys, and in the use of phys. property measurements as an aid to the study of constitution. Attention is also directed to some of the other principal problems such as age-hardening, modification and the problems raised by allotropic modification, intermetallic compds., etc. E. J. C.

Bearing of present-day knowledge of plastic deformation on the testing of metals. G. SACHS. *1st Communications New Intern. Assoc. for Testing of Materials A*, 309–15 (1930).—In the testing of metals and other cryst. materials it will in the future be necessary to bear in mind the results of modern investigations on the following points (1) The properties of a material may be different in different directions. (2) The values of the elastic consts. may be seriously affected by previous treatment and by the methods of measurement. (3) The elastic limit and the yield point are easily affected by previous cold-working. (4) The previous history of a material can subsequently be detd. from the distribution of internal stresses within it. (5) In the calcn. of structural parts it is necessary to take account of the new knowledge concerning the liability to deformation under normal and shear stresses. (6) The behavior of materials when subjected to technological processes can be calcd. on the basis of their properties as detd. by testing methods and can be checked by specially designed methods of testing. A bibliography is included. E. J. C.

Materials at high temperatures. General properties, limiting creep stress and limit of proportionality. R. G. BATSON. *1st Communications New Intern. Assoc. for Testing of Materials A*, 74–9(1930).—The general behavior of steels at high temps. under short-time tensile tests and the effect of prolonged loading in producing creep or flow and intercryst. failure are discussed. Limiting creep stresses are described and the values obtained for them are compared with results from limit of proportionality detns. and time yield tests as defined by Hatfield (*C. A.* **23**, 4429). The safe stresses to be used for design purposes are stated. E. J. C.

Materials at high temperatures. A. POMP. *1st Communications New Intern. Assoc. for Testing of Materials A*, 80–4(1930).—Tensile strength at high temps. is materially affected by the rate of testing. The time effect, however, is materially less in the detn. of the yield point or the 0.2% limit. Published results generally indicate that the yield point at high temps., for particular classes of material, bears a definite ratio to the tensile strength at room temp. In place of the lengthy tests under prolonged loading, Pomp and Dahmen propose an abridged method of testing which in the course of 1 or 2 working days permits of an approx. detn. of the so-called limiting creep stress. This is regarded as being attained when the rate of extension in the 3rd and 6th hrs. after applying the load does not exceed 0.001%. A bibliography is given. E. J. C.

Behavior of metals at high temperatures. H. STÄGER. *1st Communications New Intern. Assoc. for Testing of Materials A*, 89–96(1930).—Tests to det. the limiting creep stress were made at 400°, 500° and 600° on steel castings of widely varying compns. and on a no. of alloy steels. Rapid high-temp. tests afforded no indication of the value of the limiting creep stress. For the design and construction of machine parts intended to work at high temps. only the actual creep stress can be employed. An exact defi

nition of this stress can only be arrived at as the result of further investigation. It was found that it is not the steels contg. large amts. of alloying elements which give the best strength results at high temps., but rather those in which the alloying elements have been added in the most suitable amts. for the purpose of strengthening the material lying in the crystal boundaries. E. J. C.

Materials at high temperatures. Special alloys of iron, nickel and chromium. ROBERT HADFIELD. *1st Communications New Intern. Assoc. for Testing of Materials A*, 104–10(1930).—A review of the development of heat-resisting alloys and their use in the improvement of furnace efficiencies as metallic recuperators, conveyors for the mech. operation of furnaces, exhaust valves for internal-combustion engines, steam turbine blading and steam fittings. Of these alloys, the Fe-Ni-Cr type are probably the most useful and important. Most of the practical alloys of this type fall into 3 groups, 1 contg. from, say, 18–25% of Cr, with 7–10% of Ni, the Fe content amounting to 65–70%. The second range is higher in Ni, its percentage being in this case from 20 to 40, the Cr amounting to 10–15% and Fe 50 60%. The third group includes alloys contg. about 65% of Ni, 12% of Cr and 25% of Fe. Other elements in smaller percentages are added in many instances. E. J. C.

The micromechanical study of metals. P. A. WELIKOV, N. P. SHCHAPOV AND W. F. LORENZ. *1st Communications New Intern. Assoc. for Testing of Materials A*, 328–38(1930) — The micromech. method used by the Inst Sci. Exptl. des Transports, Moscow, for studying the mechanism of plastic deformations occurring in the materials employed in means of transport, comprises a combination of the micrographic investigation of the deformations with mech. tests on specimens of small dimensions, the 2 being carried out simultaneously on the same test piece. Tests were carried out on compressive and tensile strength, and in the latter case test specimens both with and without a notch were used. The following materials were investigated: mild steel used in bridge construction; steel for rails; fine-grained Cr and Ni steels. The rept. describes the development of permanent deformations observed. E. J. C

Nonmetallic inclusions in metals. G. F. COMSTOCK. *1st Communications New Intern. Assoc. for Testing of Materials A*, 348–54(1930).—The causes, effects, identification and elimination of nonmetallic inclusions in steel and nonferrous alloys are discussed briefly. Illustrations of the most common type of inclusions are presented, as well as Wohrman's scheme for their identification by metallographic means. Proper polishing of specimens is important. The various types should be considered separately, since the causes of their existence in metals, and the means for their elimination, are different for the different types The effects of their presence are usually, but not always, undesirable, and the prevention of segregation is of more general importance than the elimination of inclusions. E. J. C.

Physical and chemical properties of the light metals. Prescription for the mechanical testing of aluminum alloys. A. VON ZEERLEDER. *1st Communications New Intern. Assoc. for Testing of Materials A*, 257 72(1930). - The phys. consts. of Al and Mg are given and their alloys described. The standard specifications for tests on casting and forging Al alloys are stated, as they are recommended by the Swiss section of the New Intern. Assoc. for the Testing of Materials and by the European Al producers They concern the detn. of tensile strength, elongation, limit of elasticity, upper yield point, modulus of elasticity, Brinell hardness, resilience, bending capability, casting property and contraction for casting alloys and construction for forging alloys. E. J. C.

Notched-bar impact test—standard test piece. M. MOSER. *1st Communications New Intern. Assoc. for Testing of Materials A*, 222-4(1930).—The Charpy test piece is not altogether satisfactory. Both producers and users of materials are looking for a new test piece on the following lines: (1) The specimen must be small so as to enable each part to be tested without unreasonable expense. (2) The shape must be such that the various mech. conditions of the material are widely differentiated at room temp. (3) The range of application must be as wide as possible so that auxiliary test pieces are only necessary in exceptional cases. (4) It must be easy to make; the tools commonly available in a workshop are used. Various proposals are illustrated. The German standard notched-bar test specimen, the principal features of which are already fixed, corresponds closely to the test specimens used in other countries. E. J. C.

Notched-bar impact tests—standard test piece. R. PAWLISKA AND M. SCHMIDT. *1st Communications New Intern. Assoc. for Testing of Materials A*, 217 21(1930).—No simple proportionality exists between notched-bar test specimens of various forms, and the test results are influenced by the temp., shape of the specimen and by the speed of the test. For plain and alloy steels, distinction must be made between high and low values for the impact toughness; the development of these, with reference to the

above-mentioned influences, is described in detail. Since the values obtained for impact toughness are not only dependent on the material and its treatment, it appears advisable to introduce a standard test specimen, for which Mesnager's specimen with a sharp-angled V-notch is proposed. E. J. C.

Meaning of the notched-bar impact test for investigation and for acceptance test purposes. R. H. GREAVES. *1st Communications New Intern. Assoc. for Testing of Materials A*, 225–30(1930); cf. *C. A.* **23**, 5137.—The essential feature of the test is concn. of stress by the notch. Fracture may occur (*a*) by shear accompanied by considerable deformation, (*b*) by 3-dimensional tensile stress accompanied by little deformation. The transition from 1 type to the other may be brought about by relatively small changes in dimensions of the test piece or form of notch, or of speed or temp. of deformation. The result of a single test may be misleading on account of the existence of this transition zone, which, however, is more remote from standard conditions of testing for alloy steels than for C steels. A poor impact figure indicates a decided liability to fail prematurely under localized stress, but the demand for a good impact figure tends to eliminate the class of material in which failures due to adventitious causes are liable to occur. E. J. C.

Tensile and impact tests at low temperatures. P. SCHOENMAKER. *1st Communications New Intern. Assoc. for Testing of Materials A*, 237–50(1930).—The different behaviors of metals having the face-centered cubic lattice structure and those having the body-centered structure under plastic deformation, which makes itself evident in the phenomena of flow in a tensile test and in the occurrence of slip bands and twin crystals in the structure, is explained by the difference in the slipping capacity of these metals. The phenomena indicate that the resistance to slip is smaller in the face-centered structure than in the body-centered. Since the resistance to slip depends on the mobility of the atoms, the temp. must also be taken into account. Rise of temp. increases the mobility of the atoms, the possibilities of slip increase, and, as the expts. of Bach have shown, the yield point falls. Conversely, a fall of temp. raises the yield point (Körber, Mailänder). It is demonstrated with Cu and brass that it is possible to diminish the mobility of the atoms in the face-centered lattice by lowering the temp to such an extent that they behave like the atoms in a body-centered lattice. Impact tests, also, taken at a low temp. confirm the view that temp. has an effect on the phenomena of plastic deformation. E. J. C.

A simple method of studying the stress-strain relation in the notched-bar impact test. TADASHI KAWAI. *Science Repts. Tôhoku Imp. Univ.*, 1st Ser., **19**, 727–43 (1930).—By the ordinary method of applying the notched-bar impact test, the value of the impact energy required which is just sufficient to break the test piece is found, but not the stress-strain relation. Though the impact value is a measure of the toughness of metals, it does not give any information as to the behavior of the metals under load, as is obtained by the statical test. Hence K. has devised a simple method for detg. the energy-strain and stress-strain relation in notched-bar impact test, by using an ordinary Charpy machine. R. RIMBACH

The elastic limit in shock tests. N. DAVIDENKOV AND K. YUR'EV. *1st Communications New Intern. Assoc. for Testing of Materials A*, 231–6(1930).—An attempt was made to det. the relative increase of the elastic limit under shock, first in relation to the tensile strength (max. load) and then to the tearing strength (fracture). For this purpose polished test pieces coated with shellac were used, the change in diam. at the ends being conical so as to allow the yield point to be readily recognized. The mean relative increase for a series of C steels was found to be 25% with respect to the tensile strength (max. load), and 70% with respect to the tearing strength (fracture). As a sequel to this phenomenon, an elongation at the elastic limit under shock equal to about 4 times that obtained with a static tensile test was ascertained. E. J. C

Determination of the creep limit according to the short time test. A. POMP AND W ENDERS. *Stahl u. Eisen* **51**, 157–62(1931); *Mitt. Kaiser Wilhelm Inst. Eisenforschung* **12**, No. 10, 1930, Report 152, 127–47.—In continuation of previous investigations by Pomp and Dahmen (*C. A.* **21**, 1959; *Stahl u. Eisen* **47**, 414–5(1927)), on the detn. of the creep limit by an abbreviated method, the present investigation studied the suitability of this method which has been improved in the meantime. In this method the extension is optically measured and recorded while the specimens are subjected to a load. The accuracy of these extension measurements could be essentially increased. Four straight-C steels (C: 0.06–0.61) were tested at 300°, 400° and 500°; 3 types of cast steel contg. Cu and Ni and a 13.44% Cr steel were tested both at 400° and 500°. The results of the tests which in part have been extended over 240 hrs. indicate that a higher velocity of extension than 0.0003%/hr. can be applied between

the 3rd and 6th hr. In alteration of Pomp and Dahmen's previous suggestions the creep limit of straight-C steels is defined as that max. load at which the velocity of extension does not exceed 0.0003% between the 5th and 10th hr. G. G. NEUENDORFF

Prospects hopeful on metals for 1000–1500°F. H. W. SPRING. *Elec. World* **97,** 459–61(1931).—Greater demands are being made for steel to withstand high temps. under high-pressure conditions. Above the strain-hardening or so-called equi-cohesion temp. there is no such thing as "creep limit," creep constantly going on, but more rapidly with higher temps. and increased stresses. Large grain-sized material has greater resistance to creep than the same material with reduced grain size. Fatigue of over-stressed metal is much more important at lower temps. than at high operating temps. Boiler shells, headers, piping, etc., have a certain flexibility, but valve seats require new and more serviceable materials than the common C steels. Brass, Monel metal, Ni and Ni alloys, stainless steels and some harder alloys are used, depending upon the service desired. A proper valve seat should be noncorrosive, have a proper coeff. of expansion, have forging or casting quality, machinability, density and smooth texture, proper strength and ductility, hardness to withstand scratching, nongalling or seizing quality and be reasonable in cost. "*Nitralloy*" is being used for the purpose.
W. H. BOYNTON

Advances in microscopy. F. F. LUCAS. *1st Communications New Intern. Assoc. for Testing of Materials A,* 363–5(1930); cf. *C. A.* **23,** 73.—Specifications are given for new metallographic equipment expected to yield satisfactory results at very high magnifications (5000–7500 diams.). Developments in progress in the field of ultra-violet metallography are discussed. New optical glasses of ultra-violet-transmitting characteristics are needed and the possibilities are reviewed briefly. The advances to be expected in metallography, especially with respect to the phenomena involved in the hardening of steel and the nature of the constituents, martensite and troostite, are discussed.
E. J. C.

Progress of microscopy. H. WRIGHTON. *1st Communications New Intern. Assoc. for Testing of Materials A,* 366–8(1930).—Progress in metallurgical microscopy in Great Britain since 1920 is described. An outline is given of the work of the Roy. Microscopical Soc. in the interests of technical microscopy, of new developments in app. and of advances in microscopical and photomicrographic technic. Reference is made to the work in progress at the Imp. Coll. of Sci., where the technic of ultra-violet light microscopy is being developed.
E. J. C.

Strengthening by reversals of stress. W. SCHWINNING AND E. STROBEL. *Z. Metallkunde* **22,** 402–4(1930).—Conclusion of a previously published article (*C. A.* **25,** 1197). This article gives an account of the changes in structure (slip lines, grain boundaries, etc.) and the effect of heating (recrystn.) upon the structural changes observed.
ROBERT F. MEHL

Theory of solution of metals. II. M. STRAUMANIS. *Z. physik. Chem.,* **Abt. A, 153,** 107–11(1931); cf. *C. A.* **24,** 4688.—Polemical with Thiel (*C. A.* **25,** 673).
OSCAR T. QUIMBY

Note on the preceding contribution [on theory of solution of metals]. A. THIEL. *Z. physik. Chem.,* Abt. A, **153,** 112(1931).—Polemical with Straumanis (cf. preceding abstr.).
OSCAR T. QUIMBY

Thermal analysis and dilatometry. H. SCOTT. *1st Communications New Intern. Assoc. for Testing of Materials A,* 339–44(1930).—The salient features of methods for revealing physicochem. changes in metals at high temps. have been critically examd.; thermal analysis, dilatometry, resistance testing and magnetic testing alone are considered. Thermal analysis alone is well adapted to the detection of solid to liquid phase changes. Its chief shortcomings are inability to follow changes at a const. temp. and to measure quantitatively a sp. phys. property. The other test methods are complementary to thermal analysis in these respects. Dilatometry has the distinction of revealing under favorable conditions all types of discontinuous changes in solid metals. Elec. resistance measurements are particularly adapted to the detn. of changes in solid soly. Magnetization tests are superior for the detn. of phase relations in certain steels and permit the identification of sp. magnetic compds. in steel. There are several types of equipment available for each test method. Of those for thermal analysis, the Rosenhain furnace with the inverse rate method is the most flexible one. An autographic device for plotting such curves has been developed. The fully automatic dilatometer of Chevenard is very convenient for detecting physicochem. changes and furnishes fair values of expansivity as well. Elec. resistance and magnetization tests have unique applications, but require further development to become generally acceptable lab. tools.
E. J. C.

Heat treatment of aircraft parts. HORACE C. KNERR. *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 154-70(1930).—A general discussion. The properties of various SAE steels under different heat treatments are tabulated. For Cr Mo aircraft steel 4130X, Knerr advocates 1575–1625°F. for normalizing or quenching, and 1275–1375°F. air or 1375–1425°F. furnace, for annealing. On oil quenching, and tempering at 680–1100°F. yield points from 180,000 to 110,000 lb./sq. in. are obtained. Types of furnace equipment for various heat treatment operations are discussed. H. W. G.

Heat treatment of carburized parts. H. M. MCQUAID. *Iron and Steel of Canada* **14**, 22–4(1931).—A considerable amt. of steel, which at the present time is being given the costly double treatment subsequent to carburizing, might quite sucessfully be quenched directly from the carburizing box. The 3 methods of single-quenching carburized work are discussed, and the types of steel suitable for use when these methods are employed are described. A statement is given of the proper procedure to follow in establishing the proper heat treatment of a carburized part based on the assumption that the analysis selected has been chosen as the result of a careful study of the stresses and service to be met with in use. O. W. ELLISS

Heat treating pipe-line couplings. C. B. PHILLIPS. *Steel* **87**, No. 26, 43–5(1930).—The plant of the Dresser Mfg. Co. at Bradford, Pa., is described. LESLIE B. BRAGG

Red shortness. FRANZ HATLANEK. *Arch. Eisenhüttenw.* **4**, 207–14(1930).—In addn. to red shortness due to oxides, brittleness is also due to other causes at high temps., among them the action of gases and the presence of Mn. Brittleness produced by O at relatively low temps. can be prevented by the presence of C, Mn, Si and Al. Blue shortness is caused by oxidic inclusions, is produced earlier than red shortness, and is more difficult to overcome. H. STOERTZ

The measurement of the true specific heat of solid and liquid metals at high temperatures. H. SEEKAMP. *Z. anorg. allgem. Chem.* **195**, 345 65(1931).—S. describes a process for the measurement of the true sp. heat in which a W spiral is employed as the source of energy. Complete details of the method of supporting the spiral within the sample of metal to be investigated are given. Four diagrams are given which describe the app. used and the elec. equipment employed in connection with the expts. Particulars are given of the results of expts. on Cu, Al and Mg, the true sp. heats of which were measured in the solid state. Curves are given, showing the relationship between S.'s results and those of previous workers in this field. The application of this method to the investigation of liquid metals is described. In this case, the W spiral is protected by means of a porcelain sleeve. Measurements of the true sp. heats of solid and of liquid Tl were made from the range 18° to 500°. It is shown that Tl undergoes a transformation at the point of 226.7°, the heat of transformation amounting to 98 cal./g.-atom. O. W. ELLIS

Standardization of methods for testing the fatigue resistance of metals. K. LAUTE *1st Communications New Intern. Assoc. for Testing of Materials A*, 111–8(1930). The alternating stress resistance of a material is detd. by the endurance limit under a standardized system of dynamic loading. Its value is dependent on the 2 factors of fatigue and work-hardening. Abridged methods of testing fail because work-hardening is not completed even after a million reversals of loading. The various methods of stressing, either by steadily changing loading or by alternating impact, and the various types of stress, such as bending, torsion or alternating tension and compression cannot be regarded as interchangeable. The fatigue range varies with the chem. compn. of the material. It is diminished by occasional over-loading and depends very much on the smoothness of the surface of the test piece. Much less important are the effects of mech. or thermal treatment prior to testing, while the variations of temp. during the test itself and the frequency of alternation have no effect. The influence of the actual dimensions of the test piece is probably negligible. The great importance of the character of the surface in itself constitutes a very serious obstacle to standardization of the test. Further, the difficulty of ascertaining and keeping to a definite max. of loading in practical use makes the application of the fatigue limit for practical purposes somewhat illusory. E. J. C.

Fatigue of single crystals of pure metals. H. J. GOUGH. *1st Communications New Intern. Assoc. for Testing of Materials A*, 133–44(1930); cf. *C. A.* **23**, 2402.—The characteristics of deformation, under fatigue stresses, of single crystals conforming to each of 3 crystallographic forms, *i.e.*, face-centered cubic (Al), body-centered cubic (α-Fe) and close-packed hexagonal (Zn), are summarized. It is shown that the criterion of plastic deformation is, in every case, the max. value (max. resolved shear stress) of the shear stress component on the slip plane along one of the slip directions contained by the slip plane. The direction of slip is always parallel to the "principle line" of

atoms (that having a greater no. of atoms per unit distance than any other line of atoms in the lattice). In the face-centered and close-packed hexagonal systems, the slip plane is the plane of max. at. d. α-Fe deforms by a process of duplex slip on planes of high at. d. Fatigue cracks are initiated in the region of max. resolved shear stress, not affected, apparently, by normal stress considerations. The propagation of the crack is, however, largely assisted by tensile normal stress: the direction of propagation is often detd. by max., not max. resolved, shear stress. Reference is also made to certain theoretical deductions arising from the expts. A bibliography is included. E. J. C.

The effect of surface condition on fatigue test results. C. H. M. JENKINS. *1st Communications New Intern. Assoc. for Testing of Materials A*, 145–8(1930).—An attempt has been made to translate fatigue tests to the service conditions of such machine parts as springs, shafts with keyways, etc. The effects on the test results of such factors as the form of section, the surface finish and abnormalities in compn. and micro-structure are discussed. The accelerating influence of chem. corrosion is marked, and perhaps phys. abrasion of the surface may also weaken the material. Although the general tendency of imperfect surface conditions is to reduce the value of the fatigue strength, there appears to be a slightly increased resistance to fatigue in the case of certain surface-hardened materials. A bibliography is given. E. J. C.

Fatigue. I. Relation of the fatigue limit to the elastic limit and other mechanical properties. II. Effect of surface condition on fatigue test results. P. LUDWIK. *1st Communications New Intern. Assoc. for Testing of Materials A*, 119–32(1930). E. J. C.

Fatigue studies of telephone cable sheath alloys. J. R. TOWNSEND AND C. H. GREENALL. *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 395–405(1930).—In the study of fatigue properties of cable sheath alloys, a preliminary survey is made by use of a const. deflection method on a flat cantilever specimen at a single deflection, under which pure Pb fails in 0.3 to 1.3 million cycles and a 1% Sb alloy in 1.8 to 2.6. Alloys of refined Pb with 0.04% Ca ran for 13 million as a min. up to 169 million unbroken Very small quantities of Sn or Sb injure the Ca-Pb alloy on the test and it is stated that it will detect the effect of 0.001% As, which is not shown by tensile test. Actual endurance tests are made on a cantilever type rotating beam machine. Refined Pb, unalloyed, shows a 50 million cycle endurance limit at 215 lb./sq. in. The same with 1% Sb shows 45 and with 0.04% Ca 850 lb./sq. in. S-N curves are given. Static flow tests show an elongation in 3000 hrs. at 920 lb./sq. in. of 0.02" in 2" for the Ca alloy and 0.10" for the 1% Sb alloy. For metallographic and other data on these alloys, see Schumacher and Bouton (*C. A.* **24**, 2409). H. W. GILLETT

Constancy of the work done to cause fracture as an explanation of fracture by fatigue and other loads. K. LJUNGBERG. *1st Communications New Intern. Assoc. for Testing of Materials A*, 149–54(1930). E. J. C.

Relations between the changes in physical properties by cold working and mixed crystal formation. CURT AGTE AND KARL BECKER. *Physik. Z.* **32**, 65–80(1931).—Cold working and the introduction of impurities cause similar changes in many of the phys. properties of metals. A review is given of data on W showing these changes. Bibliography includes 75 references. T. H. CHILTON

The theory of recrystallization. J. A. M. VAN LIEMPT. *Z. anorg. allgem. Chem.* **195**, 366–86(1931).—Having assumed (1) that in the solid state only those atoms can change places, which possess an energy equal to, or greater than, a given value $E = ar_0^2$, where r_0 is the min. amplitude required to cause a change of place, and (2) that amplitudes in excess of r_0 are impossible, and having accepted Lindemann's assumption that at the m. p. of a solid the amplitude of vibration of the atoms is approx equal to the mean distance of the atoms apart, van L. develops a general diffusion formula applicable to single crystals, from which, if the distance between the atoms of the metal in which diffusion occurs, the characteristic vibration frequency, and the m. p. of the diffusing metal, and the temp. at which diffusion occurs are known, a value for the diffusion const. at the above temp. can be obtained. Hence, the relationship between the diffusion const. and the temp. of the metals can be calcd. A relationship between the diffusion consts. of deformed and undeformed metals is then evolved, and the fact that the rate of diffusion of a deformed metal in an undeformed metal is greater than that of the undeformed metal is explained. Modifications necessary to apply the theory to polycryst. materials are discussed. van L. then derives general formulas for the relationships between temps. of annealing and the times required to effect complete softening at these temps., and between the m. ps. and the temps. of recrystn. of the metals. Tables showing the relationship between observed and calcd. values are given.

The phenomena of recrystn. in solid solns. and of recrystn. in general are discussed. O. W. ELLIS

The aeration theory of Evans. E. HERZOG AND G. CHAUDRON. *Korrosion Metallschutz* **7**, 1(1931).—A reply is made to objections by Maass and Liebreich (*C. A.* **24**, 3744, 5705) against conclusions drawn from "drop" expts. Details of these expts. are given, which uphold the conclusions of the authors and the aeration theory by Evans. E. MAAS AND E. LIEBREICH. *Ibid* 2–3.—The unetched spot in the center of a drop, observed by Herzog and Chaudron (above) after adding to this drop a NaCl soln. contg. 1% H_2O_2, is assumed by the authors not to be due to a different aeration, but to be due to disturbances of convection currents caused by the introduction of the capillary pipet. It is important whether the pipet only touches the surface of the drop, or whether it penetrates beneath it. In the first case, the soln. introduced will not go down to the center of the drop, as assumed, but will, provided its d. is approx. the same as that of the drop, diffuse slowly throughout the drop. In the second case, a disturbance of the convection currents takes place, which will cause the appearance of an unetched or only slightly etched spot in the center, regardless of whether the soln. contains H_2O_2 or not. A similar unetched spot can also be obtained if, in place of a pipet, a thin glass rod with a plane polished end is immersed for only 5 or 10 min. into the drop. This cathodic spot formed in the center remains unetched even after the removal of the glass rod. LEOPOLD PESSEL

Investigation on the behavior of metal toward cleaning and disinfecting materials. M. E. SCHULZ. *Molkerei-Ztg.* (*Hildesheim*) **44**, 1439–41, 1461–3, 1495–1501, 1515–6, 1557–60(1930).—Metal sheets of 100 sq. cm. surface are immersed for 24 to 48 hrs at 45° to 50° in a soln. of the material. Change in the metal, loss in wt., tempering color, surface and pore corrosion are detd. The results are placed in a table so that the proper material can be detd. for each metal. There are no cleaning solns. which do not attack metal, but some are worse than others. The protection given by the addn of water glass and chromate is studied. The addn. of chromate to the soln. is limited by the cost. The amt. of water glass to add to solns. of a no. of com. cleansers is given. GEORGE R. GREENBANK

Metallurgy of the modern die set. JOHN H. HRUSKA. *Iron Age* **127**, 702–5 (1931).—Castings for die sets are made almost exclusively from semi-steel or a special grade of gray cast Fe. The heat treatment of die set castings is described. Increased temp. decreases hardness; prolonged heating enlarges graphite flakes of matrix and decreases transverse strength. Leader pins and bushings are made of pearlitic Mn steels. Box carburizing is desirable in long leader pins and bushings. The rotary furnace has certain outstanding features so far as quick production and low cost are concerned. Drawing may be done in rotary furnaces, salt pots or oil tanks with accurate temp. regulation. Results of analyses are tabulated. V. S. POLANSKY

Atomic hydrogen occluded in iron nitride. SHUN-ICHI SATOH. *Bull. Chem. Soc. Japan* **5**, 291–303(1930).—The presence of at. H in Fe nitride is confirmed. The evidences are: the liberation of H when Fe nitride is heated above 430° and decomposes slowly; the measurement of the single potential of Fe nitride in the normal $FeSO_4$ soln.; the oxidation of at. H by O in the water in which Fe nitride is immersed; the transformation of K ferricyanide. Nitriding changes compact Fe into porous Fe. Light does not produce any marked photochem. effect upon the single potential of Fe nitride. ALBERT L. HENNE

Nickel in aviation. GENERAL GRARD. *Aciers speciaux* **5**, 566–73(1930).—The properties of many steels are given. A. J. MONACK

Discontinuous changes in length accompanying the Barkhausen effect in nickel. C. W. HEAPS AND A. B. BRYAN. *Phys. Rev.* **36**, 326–32(1930). BERNARD LEWIS

Silver and its application to chemical plant. DONALD MCDONALD. *Soc. Chem. Ind.*, Chem. Eng. Group Feb. 13, 1931, 12 pp.; *Chemistry & Industry* **50**, 168–78 (1931).—The properties of Ag are reviewed with regard to its use in the construction of chem. equipment. The economic history, occurrence and metallurgy of Ag are discussed at length. The phys. and chem. properties reported in the literature are critically reviewed with some addnl. observations. The power of absorbing O by Ag in the molten state has been studied in detail. The more important alloys of Ag and their applications are mentioned. The properties of Ag which make it attractive for the chem. plant are: its freedom from oxidation, resistance to acids, high thermal and elec. conductivities, and excellent mech. characteristics. Various uses in the industries are mentioned. The high salvage value of Ag app. makes its use as a construction material more attractive. ALLEN S. SMITH

The resistance of chromium-plated plug gages to wear. HARRY K. HERSCHMAN. *Bur. Standards J. Research* **6**, 295–304(1931). R. RIMBACH

The structure and the mechanical properties of pearlite. N. T. BELYAEV. *Rev. métal.* **27**, 680–5(1930).—B. indicates the possibility of using the interlamellar distance in pearlite as a measure for the mech. properties of eutectoid steels (cf. *C. A.* **23**, 5454). H. S. v. KLOOSTER

The effect of certain elements upon the segregation of cementite and its relation to the modification process. J. H. ANDREW. *Roy. Tech. Coll. Met. Club J.* (Glasgow) 1929–30, No. 7, 16–7.—Speculation upon the relation between the effect of 0.25% Mo in a 3% Ni steel, or of 0.60% Mn in a 0.22% C steel, in which the Mo or Mn is said to hinder free movement of carbides, preventing them from coalescing, and thus producing a fine sorbite, and that of Na in the modification of Al-Si alloys. H. W. G.

Thermochemical data on iron. W. A. ROTH, H. UMBACH AND P. CHALL. *Arch. Eisenhüttenw.* **4**, 87–93(1930); cf. *C. A.* **24**, 2039.—The authors used azeotropic 20% HCl soln. at temps. in the neighborhood of 100° as a solvent for various Fe compds. and detd. the following heat effects, calcd. at 19°: $Fe + 0.5O = FeO + 64.2$ Cal., $FeO + Fe_2O_3 = Fe_3O_4 + 7.0$ Cal, $2FeO + SiO_2$ (quartz) $= Fe_2SiO_4 + 8.1$ Cal. and $Fe_2O_3 + 3Cl_2 = 2FeCl_3$ (cryst.) $+ 1.5O_2 + 7.4$ Cal. H. S. v. KLOOSTER

Alterations in the properties of hematite pig iron cast from the first melting. E. PIWOWARSKY. *Stahl u. Eisen* **50**, 966–8(1930).—The alterations which take place in the mech. properties of pig Fe during tapping from the blast furnace into an acid mixer from which finished castings are poured have been detd The compn. and properties of samples cast in sand and in chill molds directly from the blast furance during the charging of the mixer and during the emptying of the mixer are tabulated, the variations over a period of 7 days being shown. Sand castings have the better properties when taken directly from the blast furnace, but chill castings are superior to sand castings poured from the mixer. In both cases an appreciable improvement in properties takes place during the passage of the metal through the mixer. B. C. A.

Cast iron. E. PIWOWARSKY. *1st Communications New Intern. Assoc. for Testing of Materials A*, 5–9(1930).—The special properties of cast Fe (lack of quasi-isotropy and influence of graphite inclusions) have for a long time made it difficult to introduce standardized methods of testing. The absence of reliable inter-relationships between the mech. and phys. properties necessitates furthermore a large number of sep. investigations to det. the quality. The following measurements are now made: (1) *The static properties.*—(a) Tensile strength. Tensile tests are provided for. The fact that cast Fe is scarcely ever subjected to pure tension in practice makes this test of little value, but it is easy to carry out and to evaluate; (b) bending strength. The deflections must be given for as many loads as possible, in any case for the max load at fracture; (c) the Brinell hardness; (d) compression strength, with simultaneous recording of the stress-strain diagram and the load at which cracks begin to appear; (e) shearing strength. The test for shearing strength does not give any simple relation between shearing and tensile strength. (2) *The dynamic properties.*—The detn. of the fatigue limits will continue to be of value until smaller foundries are able to procure rotating type fatigue-testing machines. (3) *The elec. and magnetic properties.*—Experiences in testing Fe and steel may be applied. (4) *The machinability.*—The hardness boring test of Keep, Loewe or Kessner is widely used. Nevertheless the test on turning time to det. the cutting speed seems to be the only suitable one. The Brinell hardness for cast Fe bears no fixed relation either to the machinability or to the resistance to wear. (5) *The volumetric stability.*—This test still lacks any degree of uniformity. (6) *The sp. vol.*—This test is best carried out with the method of buoyancy. Measurement of the perviousness to gases appears to be of less importance. (7) *The ability to fill molds.*—Rapid and practically useful results are given only by pouring tests. The tendency to porosity and to the formation of blow-holes is shown by Cook's K-test. E. J. C.

Cast iron—methods of testing. E. DUBI. *1st Communications New Intern. Assoc. for Testing of Materials A*, 10–24(1930).—A separately cast test piece of 50 mm. diam. gives results which agree very closely with those obtained from test pieces of 30 and 50 mm. diam. machined from the main casting. Small test pieces taken according to the French specification from the main casting give valuable criteria of the nature and uniformity of the internal structure of the casting itself. As regards the strength of the material, however, these small test pieces do not give any more accurate indications than specially cast test pieces having a diam. corresponding as nearly as possible to the thickness of the wall of the casting under investigation. The strength properties of casting apparently can only be detd. conclusively from tests on the casting itself. E. J. C.

High-duty cast iron. GEBRÜDER SULZER. *1st Communications New Intern. Assoc. for Testing of Materials A*, 49–63(1930).—The methods of producing high-grade cast Fe are discussed with particular reference to the effect of a considerable reduction of C content on the properties of the Fe. As the C content diminishes, bending strength, tensile strength and resistance to impact increase, while in general the deflection remains unchanged. The shrinkage and the tendency to form cavities, however, increase, as do the general difficulties of foundry technic. The pearlitic ground mass of high-grade cast Fe has, in the cast condition, a tensile strength of approx. 70 kg. per sq. mm. By means of alloying addns., so long as the structure remains pearlitic, the Brinell hardness of cast Fe is increased while the other strength properties are not materially changed. Carbide-forming elements such as Cr, W, Mo and V increase the resistance to abrasion and to thermal effects, but reduce the machinability. E. J. C.

The results of investigations on the growth of cast iron. FRANZ ROLL. *Die Giesserei* **17**, 995–8(1930).—The views of various investigators on the influence of the compn and other factors on the growth of cast Fe are tabulated J. BALOZIAN

Cast-iron testing in Great Britain. J. G. PEARCE. *1st Communications New Intern. Assoc. for Testing of Materials A*, 1–4(1930).—A specification which has the approval of the founding industry was issued in 1928 by the Brit. Eng. Standards Assoc. While it covers only 2 qualities of Fe for general engineering castings, the testing procedure is applicable to all types and qualities. The features of this specification are as follows: The size of the test bar varies with the thickness of the casting, 3 sizes being used at present. The test bars are cylindrical and may be cast away from the casting. Both tensile and transverse tests are covered and no chem. analysis is demanded. The majority of engineering castings will be covered by the intermediate size of bar 1.2″ in diam which is virtually the standard bar used on the Continent and in America. The adoption of this basis for testing has stimulated a considerable amt. of investigation on the relations between mech. properties, but it is believed that at the present stage of development no other mech. tests can be usefully employed in general specifications. E. J. C

Heat- and acid-resisting cast irons with high chromium and carbon contents. EMANUEL VALENTA. *Iron and Steel Inst. (London) Carnegie Scholarship Mem* 19, 79–165(1930).—Three series of Cr-Fe-C alloys were studied: (I) without added elements, (II) with addns. of Si and (III) with addns of Al. (I) In this series the C content varied from 0.15 to 3.6%, while the amt. of Cr was between 4.7 and 36.9%. The Si content was 0.4% for low Cr and 0.8% for high Cr percentages. It was found that above 16% Cr the resistance to scaling is perfect. Beyond 35% Cr the heat resistance does not increase further. The proportion of primary double carbides increases with the C content. These carbides form long, heat-resistant needles which destroy the homogeneity and strength of the castings. Hence the hypereutectic alloys are of no technical importance. Below 0.5% C the alloys are more expensive and must be produced in an elec. furnace. Test bars, both prismatic and cylindrical, were prepd. for chem., metallographic, dilatometric, thermal and mech. examn. Brinell hardness detns. were made after casting, annealing and air cooling for various thicknesses and different rates of cooling. Graphs are presented showing lines of equal hardness depending on the Cr and C contents. For machinability, if a hardness of 350 is assumed to be the limit, it is necessary to keep the C content below 1.6 or 2% in alloys contg. 25 or 35% Cr, resp., in annealed specimens. For high resistance to wear and abrasion a Cr/C ratio of 10/1 may be used with advantage. The useful alloys in the Fe–Cr–C system are those contg. 1.8–2% C which may be divided in 3 zones: (*a*) alloys in which the pure δ-crystal predominates, strongly corrosion-resistant, suitable for forging and without hardening ability, (*b*) alloys showing both γ- and δ-crystals with reduced corrosion resistance and lower malleability and (*c*) alloys of pure γ-crystals with materially reduced resistance to corrosion, recommended for service at high temps. (II) The examn. of alloys contg. Si in amts. varying from 0.5 to 4.3% with Cr ranging from 20 to 35% showed that the eutectic valley is displaced to lower C percentages. Hence the range of useful hypoeutectic alloys is much lower. Addn. of 1% Si displaces the eutectic line to lower C content by about 0.3% C. The corrosion resistance is greater than for those alloys contg. no Si. With constant Cr content the effect of varying amts. of Si (0.5–2.3%) is to raise the temp. of entrance into the γ phase. For 1% Si the rise is about 80°. The effect is less for lower C content where the eutectoid temp. rises rapidly. Hence the lower the C and the higher the Cr percentage, the smaller is the amt. of Si required to suppress the hardening of alloys cooled from 1000°. For high C alloys as much as 4% Si might be required to prevent air hardening, but the product would be brittle and unmachinable. (III) Alloys with Al as addn.

element contained 1.1–2.9% C, 19.3–29.8% Cr and 0.6–2.4% Al. Even a low percentage (0.5%) of Al was in most cases sufficient to suppress entirely the self-hardening properties. The effect of Al on the raising of the critical points and upon the structure was about twice that of Si. Air cooling gave alloys with low hardness shock-resistance and good malleability. The location of the eutectic line was not materially altered by adding 1–1.5% Al; hence the range of useful high-C alloys is greater than that for Si alloys. The alloys studied are classified on the basis of the dilatometric curves obtained. Numerous tables, charts and photomicrographs are given. A suitable reagent for etching these alloys consisted of a cold alc. soln. of 5% picric acid, 2 5% HCl and 2% $FeCl_3$. H. S. v. KLOOSTER

Nickel-vanadium and nickel-molybdenum cast irons. II. JEAN CHALLANSONNET. *Rev. Métal.* **27**, 654–71(1930); cf. *C. A.* **25**, 1197.—The dilatometric and microscopic study of a synthetic cast iron contg. 3.7% C showed that the presence of 0.25 and 0.5% Mo either alone or with 1 and 2% Ni, resp., does not affect the Curie point of Fe_3C. Addns. of 0.25 and 0.5% Mo raise the Ac point 25° to 725° and in alloys with 1 and 2% Ni the added Mo raises the Ac point from 660° and 665° to 725°. On cooling the Ar point is lowered and the effect is cumulative when both Mo and Ni are present Reheating of the cast alloys brings about graphitization in the specimens contg. 1% Ni and 0.25% Mo (at 1000°), 2% Ni and 0.25% Mo (at 1050°) and 2% Ni + 0.5% Mo (at 1070°). The microstructure of all 6 alloys when fast cooled showed no graphite. Mo refines the pearlitic constituent and produces small bright spots, possibly complex Fe-Mo carbides which diminish in size in the presence of Ni. The com. cast irons were the same as those used previously for prepg. Ni-V cast irons and distinguished as A, B and C, resp. In each group 6 alloys were studied contg. approx. 1% Ni + 0.25% Mo, 1% Ni + 0.5% Mo, 2% Ni + 0.25% Mo, 2% Ni + 0.5% Mo, 0.25% Mo and 0.5% Mo. All alloys as obtained after casting contained both graphite and cementite. Mo favors somewhat the cementite formation at low C contents (2.5%) but the graphitizing effect of Ni is only slightly changed by Mo. Dilatometric curves show sudden expansions on heating at temps. below the Ar point for all alloys contg. Ni. This expansion, due to graphitization, is absent in alloys contg. only Mo addns. when heated to 1000°. A study of the effect of the rate of cooling on the microstructure indicated that no complex carbides were produced in the com. cast irons but that Mo, like Ni, increases the hardness of the pearlitic matrix. With a C content as high as 3.5% C, Mo does not noticeably increase the percentage of combined C. Contrary to the effect of V on rapidly cooled cast irons contg. Ni, Mo does not prevent a martensitic quench. Tables, graphs and photomicrographs accompany the article. No definite conclusions could be derived from the data obtained. H. S VAN KLOOSTER

Non-metallic inclusions in iron and steel. A. BAIKOV. *1st Communications New Intern. Assoc. for Testing of Materials A*, 355–62(1930).—The non-metallic inclusions in cast metal are generally present in only very small proportions (tenths or hundredths of 1%), and usually consist of S and O compds. The sulfurous inclusions are solid solns., and the O compds. are fused matter resembling a slag. If this view of the nature of inclusions is correct, then the way in which they are distributed is detd. by the circumstance that the complete constitutional diagram of the system: cast metal + material of the nonmetallic inclusions exhibits the phenomena of limited soly in the liquid state and forms 2 liquid layers. Nonmetallic inclusions with a m. p. lower than that of the metal are of a totally different character. In this case the inclusions are in the form of drops and retain their spherical shape while surrounded by the solidified metal. The third type of nonmetallic inclusions is observed in metals with low Mn content, considerable quantities of S and low C content. In this case practically the whole of the S forms Fe sulfide. With excess metal, the nonmetallic inclusions solidify at the end of the crystg. process, forming a skin of eutectic alloy around the grains of the segregated metal. E. J. C.

Report of research committee on yield point of structural steel. W. O. M. WITHEY, *et al. Proc. Am. Soc. Testing Materials* **30**, Pt. I, 133–58(1930).—In a coöperative study, the yield point of specimens cut from structural shapes of 16 different sizes and shapes, ranging from $^3/_8$" plate to 26" girder beam and made from steel of 0.14 to 0.29% C, 0.37 to 0.73% Mn, was found to range from 29,000 to 39,000 lb./sq. in. depending on variations in rolling and cooling conditions, on finishing temp., on size of section and position of the specimen in the section. The ratio of yield point by drop of beam to tensile strength ranged from 0.50 to 0.65; hence it cannot be estd. with sufficient accuracy from the tensile values. There was considerable discrepancy between mill tests and the more carefully conducted coöperative tests. A single specimen will not adequately represent the av. properties of heavy girder beams and H-column shapes

and 3 specimens from intermediate flange, root and web should be taken. If only one is taken, it should come from the intermediate flange. The most representative single specimen is from an intermediate location in plates and angles and from the center of the web in channels and I-beams. H. W. GILLETT

Mechanical properties of British steels. W. E. DALBY. *Proc. Inst. Civil Eng.* (London) **227**, 25–61(1928).—Slipping stresses are calcd. from (1) the non-load-to-break diagram, (2) the elastic diagram, (3) the push-pull diagram, and (4) the torque-twist diagram to indicate the stress at which slip begins for Bessemer acid steel, open-hearth basic, open-hearth acid (0.52% C), open-hearth acid (0.63% C) and Ni-Cr steels. Elastic twist changes gradually to plastic twist, the change being more marked in Bessemer steel. The elastic diagrams are similar but limits of proportionality vary greatly. ANN NICHOLSON HIRD

The macroexamination of steel. Metallographic methods used at the Watertown Arsenal. M. G. YATSEVITCH. *Army Ordnance* **11**, 297–305(1931).—Prepn. methods are discussed and objects of tests, etc., are considered. Examples are given. Three tables on quantity of reagents, etching times, etc., are given. The interpretation of the picture revealed on the surface of the metal is discussed. M. F. BEHAR

Selection and heat treatment of ball- and roller-bearing steels. ERNEST F. DAVIS. *Fuels & Furnaces* **9**, 153–62(1931).—Ball steels contain 1% C and 0.75–1.65% Cr, depending upon ball diam. Smaller sizes have lower Cr contents. Failures of balls in service result from surface defects, surface decarburization, excessive carbide segregation, and the commoner defects such as inclusions and center segregation. Steels for races are the high-C-Cr steel and the carburized grades such as the Ni-Mo, and the 3.5% Ni. Most widely used steel for carburized races is SAE 4615. Roll steels are the high-C-Cr steel, spring steel of modified SAE 4150 analysis and the carburized grades. Analyses are given of the various steels and methods of heat treatment are outlined. R. RIMBACH

The strength of steels at high temperatures. H. A. DICKIE. *Roy. Tech. Coll. Met. Club J.* (Glasgow) **1929-30**, No. 7, 32–7.—A brief general discussion. H. W. G.

Effect of rate of cooling on the structure and constitution of steel. J. M. ROBERTSON. *Safety in Mines Research Board Paper* No. 59, 57 pp.(1930).—The effect of variation in the rate of cooling steel cannot be accounted for by the supposition that an increased cooling rate produces in turn sorbite, troostite and martensite, as many other different forms of structure are evident between these states. It is suggested that the constitution of steel should always be considered in terms of the quantity of α-solid soln., γ-solid soln. and cementite present and their relation with one another. Four series of structures may be obtained by different methods of cooling. The first includes all structures consisting of ferrite and pearlite or the latter alone. Again, continuous rapid cooling which suppresses the Ar1 and lowers the Ar2 point produces the series of quenched steels, the structure of which may be varied considerably. When cooled so that the Ar1 point is suppressed and the rate then retarded so that the Ar2 change takes place at const. temp., a 3rd series results, and a 4th is similar except that the steel is withdrawn before the change is complete, the final change being effected by atm. cooling. The general arrangement of all ferrite-pearlite structures is detd. by the manner in which ferrite develops from austenite, but the structure of the grains of pearlite is detd. by simultaneously formed ferrite and cementite. The only structures which temper in a different manner are those which contain a considerable quantity of α-solid soln., since, during reheating, decompn. of this α-phase occurs by the gradual sepn. of C as the temp. is raised and not by a sudden pptn. of fine C with subsequent coalescence to form larger globules. B. C. A.

Effect of the state of the cementite on the heat sensitivity, the tendency to core-hardening and formation of hardness fractures in carbon steels. S. STEINBERG. *Stahl u. Eisen* **50**, 1164–6(1930).—The effect of various heat treatments on the microstructure and mech. properties of steels with 0.8 and 1.3% C has been investigated. The hypoeutectoidal steel after annealing at 950° and slow cooling becomes hard and tough after hardening at 735° and quenching; hardening at 750–800° produces a more coarsely crystalline structure, and the metal becomes brittle with a tendency to develop hair-cracks. The hypereutectoidal steel requires very slow cooling after annealing at 950° and a hardening temp. of 800–50° to produce a tough structure. Lamellar cementite causes brittleness and hair-cracks to develop on hardening, whereas granular cementite or troostite imparts a high degree of toughness to steel. B. C. A.

Temper hardening of steel containing copper. H. BUCHHOLTZ AND W. KÖSTER. *Stahl u. Eisen* **50**, 687–95(1930).—The solid soly. of Cu in α-Fe is 0.4% at 0–600° and then increases according to the equation, $\log x = -4125/T + 4.32$, to 3.4% at the

eutectoid temp., 810°. On cooling a Cu steel from the γ-solid soln. range, supersatd. solid solns. of Cu in α-Fe, having a structure resembling that of martensite, may be obtained; these supersatd. solns., as well as those contg. 0.6–3.4% Cu quenched at 600–800°, undergo age hardening on tempering at 450–600°, but the sepn. of the excess Cu in a highly dispersed condition and the subsequent coagulation of the particles take place very slowly. When the steel contains both Cu and C in supersatd. solid solns., both elements sep. in a disperse form on aging at high temps., the 2 reactions taking place independently of one another. Thus on tempering a quenched steel with 0.05% C and 2% Cu at gradually increasing temps., the hardness rises sharply from 160 to 210 at 20° during 3 days, then to 220 at 100° because of sepn. of excess C; the hardness then falls rapidly to 150 at 300°, because of coagulation of the cementite, and rises again to 205 at 500–550° because of pptn. of the Cu. The properties of temper-hardened forgings of steel with 0.8% Cu and 0.4% Cr resemble those of a Cr-Ni steel with a tensile strength of 70 kg./sq. mm.; both steels are characterized by the regularity of their mech. properties throughout large cross-sections and by their stability on prolonged storage after tempering. B. C. A.

The malleability of rolled soft steel and a new method for its improvement. JOSEPH VIETÓRISZ. *Iron and Steel Inst. (London) Carnegie Scholarship Mem.* **19**, 167–213 (1930).—Tensile tests and microscopical investigations were performed on a com. open-hearth mild steel contg.: C 0.05, Mn 0.29, P 0.02 and S 0.035%. Specimens obtained from the same billet (heated to 1350° and rolled in 8 passes at 1200°) were rolled at temps. ranging from 1280° down to 20°. Test pieces were then taken both in the direction of rolling and across. The following quantities were detd. for various degrees of deformation: yield point, traction hardness, uniform and total elongation, tenacity, stress in contracted section of fracture, malleability, reduction in area, tensile strength and no. of grains in a given field of vision. The changes in properties were recorded in graphs as a function of the rolling temp. The main results are summarized as follows: Between 700° and 850° all mech. properties have very low values; this range may be taken as the dividing line between hot- and cold-rolling. Uniform and total elongation are at their max. value on rolling at 900° and reach a min. at 300°. Rolling between 200° and 400° gives a fairly const. max. value for yield point, traction hardness and tensile strength. At const. temp. these quantities, as a rule, increase when the degree of deformation increases. The tenacity curve shows a rise at 850°, falls rapidly between 850° and 750°, then rises again at 700° and drops to its lowest value at 300°. The grain no. increases rapidly with decrease in rolling temp. to 850°, but below 700° no appreciable change in grain no. is found. After rolling between 200° and 550° a special etching method with the aid of Fry's reagent brings out characteristic slip figures at angles of 45° to the direction of compression parallel to the direction of rolling and in the form of horizontal lines across the direction of rolling. Rolling at room temp. produces merely slipbands, serrated crystal boundaries and broken crystals. It is suggested that recrystn. of specimens rolled between 200° and 400° will produce the finest structures and the best mech. properties. This tentative conclusion is contrary to the customary practice of recrystallizing material rolled at room temp.
H. S. v. KLOOSTER

Carburization and decarburization of carbon steels. TAKEJIRO MURAKAMI AND HARUJIRO SEKIGUCHI. *Tetsu-to-Hagané (J. Iron and Steel Inst. Japan)* **16**, 1015–40(1930).—C steels with 0.29, 0.70, 1.02 and 1.29% C were treated at 800°, 900° and 1000° with different kinds of carburizing agents. With pure C powder, decarburization was already noticed at 800° in steels whose C content was higher than 0.3, especially when the packing was insufficient. Carbonate salts prevent this effect, though slight decarburization was found at initial stages. Carburizing speeds can be accelerated by the addn. of $BaCO_3$ till the amt. of the salt reaches 40%; the addn. of $NaCO_3$ to this mixt. promotes the tendency. When the carburizing temp. exceeds 900° fine particles of C adhere to the steel surface. It is easy to carburize up to the Acm point, but the carburizing speed drops suddenly above this. Small quantities of moisture in C are preferable for carburization, and the size of C powder has no effect on the speed. M. KURODA

The effect of carbon on the transformation points and hardness of 12% chromium steels. TAKEJIRO MURAKAMI AND YOSHIRO FUJII. *Kinzoku-No-Kenkyu (J. for Study of Metals)* **7**, 505–23(1930).—By measurements of the thermal dilatation and the magnetization of 8 specimens contg. about 12% Cr with const. and varying C contents of less than 2.04% during heating and cooling under different conditions, the change of transformation points of these specimens was studied. The effect of C on the A_1, A_2 and A_3 points in slow heating and cooling from 900° and 1100° with different ve-

locities was carefully observed, and the results were shown in curves. The Brinell hardness of specimens cooled under the same varying conditions as above, or quenched in oil from 900°, 1000°, 1100° and 1200°, or quenched and tempered at several temps. was measured. From the results, the change of hardness with the C content and with the several heat treatments was plotted in several curves and discussed in detail. The microstructure of these specimens and its change under several heat treatments were also described. M. KURODA

Manganese steel. HEINRICH KREUTZ VON SCHEELE. *Giesserei-Ztg.* **27**, 98–100 (1930).—A review of the prepn. of high Mn-steel castings. CURTIS L. WILSON

List of alloys. WM. CAMPBELL. *Proc. Am. Soc. Testing Materials* **30**, Pt. I, 336–97(1930).—Campbell's list of non-ferrous alloys, which has been so useful for reference, has been brought up to date, and greatly enlarged. There are about 8000 compns. listed. The phys. properties of the standard and widely used alloys are given from the Am. Soc. for Testing Materials specifications and other sources. H. W. GILLETT

Comparison tests on light metal piston alloys. M. v. SCHWARZ. *Z. Metallkunde* **22**, 417–9(1930).—An app. is described for detg. the performance of a piston in service. Data obtained with it are used to compare Al alloys and cast Fe used in piston manuf. ROBERT F. MEHL

Measurements on the superconductivity of alloys. J. C. MCLENNAN, J. F. ALLEN AND J. O. WILHELM. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 53–64(1930); cf. McLennan and Quinlan, *C. A.* **25**, 2050.—The supercond. transition points of a no. of alloys contg. Sb, As and Sb were measured to compare the effect produced with that of metals from other groups. Most metals when alloyed with superconductors do not affect the supercond. appreciably. Au apparently lowers the supercond. transition point of some metals while with one exception the metals of the Bi group elevate the transition temp. of the metal with which they are alloyed. Tables giving the transition temp. for the alloys examd. are included. J. W. SHIPLEY

Methods of mechanical testing of light aluminum alloys used in automobile and aircraft construction. S. S. NEKRYTI. *1st Communications New Intern. Assoc. for Testing of Materials A*, 277–92(1930).—Investigations were carried out to det. the methods of testing which best show the influence of the following factors: heat treatment, the addition of other metals (Mg, Fe) to the alloy, and methods of casting. Tensile strength, compression strength, elongation and the results of a bending test with a single blow are not affected by these factors. On the other hand, the following tests are sufficiently sensitive to enable the mech. properties to be estd. and to det. the influence of the factors under investigation: bending strength, limit of proportionality under compression, limit of endurance (fatigue test), rupture under repeated blows, alternating tensile and compressive stresses by repeated blows and shortening under compression. A definite relation exists between the results of these tests and the elements of construction. The best method for detg. the resistance to corrosion is the soly. test for 15 min. in a 10% soln. of HCl. There is a relation between the results of this test and those of the fatigue tests. No difference is observable between the mech properties of specimens cut from the main casting and those of specimens cast separately. Al alloys can be hardened even if they contain no Mg. The addn. of Mg up to 0.6% and of Fe up to 1.0% increases considerably the hardness and the strength after hardening. Like all other metals, Al alloys have a safe limit of fatigue stress. E. J. C.

The notch toughness of a few aluminum alloys especially at low temperatures. W. A. GÜLDNER. *Z. Metallkunde* **22**, 412–6(1930).—Conclusion of a previously published article (cf. *C. A.* **24**, 5009). The influence of velocity of test, of the width of the test piece, and of the depth of the notch, all at —190° were studied. The relations between these conditions is expressed mathematically and graphically, and discussed at length with comparison to Fe alloys. ROBERT F. MEHL

Aluminum alloys containing nickel. W. C. DEVEREUX. *Brass World* **27**, 31–5 (1931).—The manuf. and applications of "Y" and "RR" alloys are outlined. "Y" metal contains 4% Cu, 2% Ni, 1.5% Mg, balance Al; "RR" contains 1.3–2.25% Cu, 1.3% Ni, 0.1–1.6% Mg, 0.1–0.8% Ti, 0.5–2.2% Si, balance Al. The manuf. of Cu hardener, Ni hardener and Cu-Ni hardener is also outlined. Applications of "Y" and "RR" alloys include aero and automobile engineering, cylinder heads and pistons, connecting rods, propellers, crank cases, bus frames, etc. W. H. BOYNTON

The advantages of titanium additions to aluminum. H. RÖHRIG. *Metallwirtschaft* **10**, No. 6, 105–11(1931).—It is difficult to alloy Ti with Al on account of the high m. p. of Ti. The best method is to add TiO_2 to the Al ore and reduce the 2 together electrolytically. Ti added to Al in small quantities forms either $TiAl_4$ or $TiAl_3$, a

brittle compd. Pure Al has a very coarse-grained structure. By alloying with small quantities of Ti, 0.01 to 0.03%, the grain size is reduced considerably. This is illustrated by macrographs. Sheet Al, 1 mm. thick, contg. 0.01-0.19% Ti, was annealed at 500°, stretched cold 2, 5 and 10% and then annealed at 600°. The samples were etched in HCl-HF to show the recrystn. structure. With the higher Ti contents the grain size was smaller, but the difference was less noticeable with the 10% cold-worked samples. With Ti-free Al recrystn. begins at 300°, with 0.19% Ti at 350°. The influence of these small quantities of Ti on the tensile strength and ductility is slight. The tensile strength of the samples contg. Ti which were hard rolled, and those which were annealed at 350°, was slightly higher and the ductility lower. For those annealed at 450° and 500° the reverse was the case. Corrosion tests were made by immersing samples for 1 hr. at 20° in 4 parts HNO_3, 4 parts H_2O and 1 part HCl. The loss in weight increased in the following order: annealed at 500° (least), annealed at 450°, at 400°, at 350°, hard rolled (most). Samples contg Ti lost less weight than those without Ti. Those which were annealed during the hard rolling process lost more weight than those not annealed. C. E. MACFARLANE

Study of iron–aluminum–carbon alloys. O. v. KEIL AND O. JUNGWIRTH. *Arch. Eisenhüttenw.* **4**, 221–4(1930).—The most suitable melting methods for the production of Fe-Al-C alloys are detd. Up to 14% Al, the eutectic temp. rises from 1145° to 1300° and then slowly falls again. With 1% Al, the eutectic point is reduced by about 0.16% C. The greatest formation of graphite lies between 3 and 20% Al; between 12 and 18% Al the melt when chilled is white. With increasing Al content 2 new constituents are formed: Phase I, which is low in C, microscopically homogeneous but easily sol. in acid; and Phase II, probably an Al-Fe carbide with great stability against acid attack. H. STOERTZ

Electrical conductivity of some bismuth alloys at low temperatures. J. C. MCLENNAN, J. F. ALLEN AND J. O. WILHELM. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 25–35(1930).—A no. of alloys contg. Bi were prepd. and their super-conducting transition temps detd. with an accuracy of about 0.1°K. The transition temps. found were 58% Bi and 42% Pb 8.8°K., Rose's metal (Bi_2SnPb) 8.5°K., Newton's metal (Bi 50, Sn 19, Pb 31%) 8.5°K., Wood's metal (Sn 12.5, Cd 12.5, Pb 25, Bi 50%) 8.2°K., Bi_5Tl_3 6.4°K., Pb 83 and 17% Sb 6.6°K. The presence of Bi in an alloy tends to raise the superconducting temp. while the presence of Sb sometimes raises and sometimes lowers the superconducting point. The Pb-Bi alloy has a superconducting point 1.6°K. higher than any other previously obtained. Attention is drawn to the inadequacy of all the theories of elec. cond. in metals in that they do not account for the phenomenon of superconductivity. A suggestion is made that superconductivity may be due in part, at least, to the directive action of magnetic forces within the atom. J. W. SHIPLEY

Constitution of the cadmium-rich alloys of the system cadmium–silver. P. J. DURRANT. *J. Inst. Metals*, Advance Copy, No. **549**, 15 pp.(1931).—Alloys contg. up to 40% Ag were studied microscopically and by means of heating and cooling curves. There are 3 peritectic lines, and 3 solid solns. in this area. The solid soly. of Ag in Cd is 6.0% at 343°, and 5.2% at 250°. The second solid soln. includes 18–33.5% Ag, the third more than 36% Ag. Also in *Metal Ind.* (London) **38**, 403–6, 415(1931). J. L. GREGG

Copper alloy systems with an α-phase having variable limits and their use for the hardening of copper. M. G. CORSON. *Rev. mét.* **27**, 83–101, 133–53, 194–213, 265–81 (1930).—An account is given of the investigations leading up to the development of the so-called "Corson alloys" which have been the subject of numerous patents in recent years. The alloys consist of Cu with small percentages of Cr, Co, Si, or silicides of Ni, Co, Fe or Cr, all of which constituents have a higher solid soly. at high temps. than at the ordinary temp. Between 20° and 1000° the solid soly. of Cr in Cu varies from 0.05 to 0.8%, of Co from 0.35 to 3.4%, of Co_2Si from 0.3 to 3.3%, of Ni_2Si from 0.7 to 8.2%, of Fe from 0.2 to 3.8% and of Si from 2.8 to 7.5%. Alloys contg. silicides are best hardened by quenching from 800° to 1000° and aging at 250–450°; these alloys should contain a slight excess of the 2nd metal over that required to form its silicide so as to insure max. hardening on aging without the serious fall in elec. cond., which is produced by the retention of Si in solid soln. Photomicrographs of numerous alloys of this type are reproduced, and the effect of heat treatment on the mech. and elec. properties and on the structure is illustrated by graphs and photographs. B. C. A.

X-ray investigation of copper-arsenic alloys. NOBUYUKI KATOH. *Z. Krist.* **76**, 228–34(1930)(in English).—See *C. A.* **25**, 272. L. S. RAMSDELL

Investigation of the effects of impurities on copper. VII. The effect of antimony

on copper. VIII. The combined effect of antimony and arsenic on copper. S. L. ARCHBUTT AND W. E. PRYTHERCH. *J. Inst. Metals*, Advance copy, No. 546, 33 pp.(1931); cf. *C. A.* **24**, 2705.—Alloys contg. less than 0.02% O were investigated. Those contg. up to 0.47% Sb rolled hot, while one with 0.85% Sb was hot short. Annealed ingots contg. up to 0.85% Sb could be cold rolled. All alloys contg. 0.47% or less Sb could be rolled into thin sheet. Sb increases the strength without appreciably affecting the ductility. The endurance limit of the annealed 0.47 Sb alloy was 7.8 tons/sq. in. as compared with 5 or 6 tons/sq. in. for pure Cu. The softening temp. is raised by Sb, its effect being greater than that of As. The limit of soly. of Sb in solid Cu was detd. microscopically as approx. 10%. The addn. of As to alloys contg. Sb had only a slight effect on the properties. All of the alloys had high impact strengths. J. L. G.

The equilibrium diagram of copper-tin alloys. MATSUJIRO HAMASUMI AND SEIJI NISHIGORI. *Kinzoku-No-Kenkyu (J. for Study of Metals)* **7**, 535–51(1930).—There are many structures of Cu-Sn alloys (especially those contg 10–40% Sn) that are hardly explainable by any of the existing diagrams. The latest diagram is probably that of Raper. H. and N. prepd. bar specimens of 15 cm. length and 5 mm. diam. in spite of their glass-like brittleness and measured the change of elec. resistance and the thermal dilatation on heating. Thermal analyses and microscopical examns. on the quenched specimens were made, and the equil of the system in the solid state was detd. There are 2 intermetallic compds., namely, δ and η, in this region, corresponding to the chem. formulas Cu_3, Sn_8 and Cu_3Sn. The compd. δ, formerly considered to have the formula Cu_4Sn, is proved to be Cu_3Sn_8, as pointed out by Westgren. The compound η undergoes a transformation at 675° to the solid soln. γ. This transformation accompanies an expansion of 0.56% of its linear dimension, which is twice as great as that of γ-iron to α-iron. There are 3 eutectoid transformations at 510°, 570° and 630°, corresponding to the equil. $\alpha + \delta \rightleftarrows \beta$, $\delta + \eta \rightleftarrows \epsilon$ and $\beta + \eta \rightleftarrows \gamma$, and 2 peritectic transformations at 580° and 625°, corresponding to the equil. $\delta \rightleftarrows \beta + \epsilon$ and $\epsilon \rightleftarrows \beta + \eta$. The transformation of δ and η into ϵ accompanies a linear expansion of 0.25%, which is nearly equal to the expansion of γ-iron into α-iron. The typical dilatation-temp. and resistance-temp. curves of the samples are shown. The change of the direction of the curves on heating exactly coincides with the equil. diagram given. The existence of the new phase ϵ is also clearly proved by the microscopic examn. of the quenched specimens. M. KURODA

X-ray examination of the lattice structure of the ϵ phase of the copper-tin system. J. O. LINDE. *Ann. Physik* [5], **8**, 124–8(1931).—An alloy with exactly 25 at. % Sn was prepd. from pure materials, melted in a H atm. and carefully homogenized. After powdering in an agate mortar it was heated in an evacuated glass tube for 40 hrs. at 400° and then subjected to the x-ray examn. with an angle range of 25–75°. Extra lines, not formerly observed, were found, which could not be identified as lines of the hexagonal lattice with only 2 atoms in the elementary range. These lines were found to be surprisingly strong by choosing an 0.2 mm. camera opening and an exposure of 17 hrs. Being dissolved into their α doubles, they could be measured very well. The indices of all the lines observed could be detd. These extra lines found indicate a regular distribution of the 2 kinds of atoms in the lattice, which is in agreement with the low elec. resistance of Cu_3Sn. It was not possible to find a simple at. arrangement, with hexagonal symmetry, which would explain all the lines observed. The lattice appears to be very complicated. LEOPOLD PESSEL

Alloys of iron, nickel and chromium. M. A. GROSSMAN. *1st Communications New Intern. Assoc. for Testing of Materials A*, 97–103(1930).—A review of the properties and uses of these alloys. Fe-Ni alloys are used with various proportions of Ni to give high elec. resistance, low thermal expansion, high permeability and to form permalloy (78% Ni). Fe-Cr alloys are used for their stainless properties and stiffness at high temps. Ni-Cr alloys (80–90% Ni, 20–10% Cr) give high elec. resistance combined with resistance to oxidation and are therefore used for elec. heating elements. Fe-Cr-Ni alloys are rustless, readily worked and have a high creep stress. Alloy steels may contain from 0.5 to 4% Cr, giving great hardness, or from 0.5 to 5% Ni to give toughness. Ni and Cr may also be combined with other alloying elements. E. J. C.

Tensile properties of alloy steels at elevated temperatures as determined by the "short-time" method. WILLIAM KAHLBAUM, R. L. DOWDELL AND W. A. TUCKER. *Bur. Standards J. Research* **6**, 199–218(1931).—The materials tested were a plain carbon steel and commercial alloys of Cr, V and Fe with and without addns. of W, Si or Al; also Cr-W, Ni-Mo and several austenitic steels with and without W. Metallographic study revealed very little intercryst. weakness and no marked or significant change in structure resulting from the high-temp. tests. The addn. of W increases the "structural

stability" of the austenitic alloys. Hardness was detd. as a further indication of tempering which might have occurred during the heating. A comparison of "short-time" test and "flow test" for pearlitic and austenitic steel is included. R. R.

Mechanical and physical properties of magnesium alloys. S. L. ARCHBUTT. *1st Communications New Intern. Assoc. for Testing of Materials A*, 251–6(1930)—A review of the results of the investigations carried out during recent years on Mg and its alloys. Important progress has been made in regard to purity of the metal and foundry technic, but intensive research is necessary regarding heat treatment and modification processes. Al, Zn and Cu are the chief alloying elements at present in com. use, and curves are given showing the tensile strength and ductility of binary alloys of Mg with these metals as well as with Ni. Four tables are also included showing the results of numerous tests carried out by various bodies on Mg alloys. E. J. C.

Compression diagrams and temperature-hardness curves of some lead-tin-antimony alloys. EDUARD HERTEL AND ARTHUR DEMMER. *Metallwirtschaft* **10**, No. 7, 125-6(1931) –Compression stress-strain diagrams were prepd. for 12 Pb-Sn-Sb alloys, with samples 20 mm. diam. and 25 mm. high; the load was applied at the rate of 0.01 mm. per sec. These results and Brinell hardness tests are shown in the tabulation. In 10 x-ray examns., the existence of a tetragonal Sn rich, a trigonal Sb-rich and a cubic constituent was found and the absence of any definite Sn-Sb compds. was proved.

No.	Compn. Sn	Pb	Sb	Cu	Ni	Mg	P	Load, kg /sq. mm. at Compression 0.2%	0.4%	0.9%	1 8%	3.6%	Brinell hardness at 20°	100°	Ratio 0.4%/0.2%

C. E. MACFARLANE

Silver-cadmium alloys. E. R. THEWS. *Deut. Goldschmicde-Ztg.* **33**, 56–8(1930). B. C. A.

Alloys of zinc and manganese. N. PARRAVANO AND V. MONTORO. *Mem. accad. Italia, Classe sci. fis. mat. e nat.* **1**, Chim. No. 4, 19 pp.—A study of the binary alloy Zn-Mn by the x-ray method. Alloys studied contained up to 23.3% Mn. In these alloys 3 different phases were detd.: (1) a solid soln. of Mn in Zn, the η phase, with hexagonal lattice that is similar to that of Zn, having up to 0.98% Mn; (2) an ϵ phase with hexagonal lattice different from that of Zn. This corresponds to the compd. $MnZn_7$, which contains 16 atoms ($2MnZn_7$); (3) a γ phase, with body-centered cubic lattice, corresponding to the compd. $MnZn_3$ and having 48 atoms ($12MnZn_3$) per unit lattice. G. T. MOTOK

The influence of third metals upon the constitution of the brasses. III. The effect of tin. O. BAUER AND M. HANSEN. *Z. Metallkunde* **22**, 405–11(1930).—Continuation of previously published articles (cf. *C. A.* **25**, 1202). The exptl. methods are described and the results expressed in diagrams representing sections of the ternary system. The results are summarized in a partial ternary three-dimensional diagram. ROBERT F. MEHL

Influence of the degree of rolling on the properties of α-brass. N. DAVIDENKOV AND V. BUGAKOV. *Metallwirtschaft* **10**, 1–6(1931).—α-Brass (62.95% Cu, 37.03% Zn) was rolled to thicknesses corresponding to reductions varying from 0 to 80%. The tensile strength, elastic limit, elongation, Brinell hardness, the soly in HNO_3 and the micro- and x-ray structure in the rolled condition were investigated. Between 20 and 30% reduction there is a crit. region where all curves of properties plotted against % reduction show discontinuities. On annealing at 200° the change in proper-

ties becomes continuous, showing that the discontinuities are caused by internal stresses. C. H. LORIG

Deep-etch test of brass. W. F. GRAHAM AND L. A. MEISSE. *Trans. & Bull. Am. Foundrymen's Assoc.* **2**, 810–25(1931).—Deep etching of brass with a soln. of HNO_3 (1.42 sp. gr.) and 10% by vol. of HCl (1.18 sp. gr.) clearly brings out areas of discontinuity of the structure caused by sonims, crystal boundaries or dendrites. C. H. L.

Some properties of silicon "Al-bronzes." L. J. BRICE. *J. Inst. Metals*, Advance copy, No. **547**, 18 pp.(1931).—The effect of Si on the mech. properties of Cu base alloys contg. 5, 7¼ and 10% Al was detd. The alloys were tested as cast, as cast and annealed by heating to 800° followed by air cooling, as quenched in oil from 800° or 600° and a few as forged. Si contents were as high as 4.5%. With 5% Al the addn. of up to 2% Si improves the properties. Further increase of Si increases the strength but lowers the ductility rapidly. An annealed 5% Al, 3.5% Si alloy has the properties of a 10% Al alloy. The addn. of up to 4% Si to the 7¼% Si alloy progressively increases the strength and decreases ductility. With more than 3% Si the ductility is so low as to render the alloy useless. The addn. of even 1% Si to the 10% Al alloy produces a very low ductility. A microscopic study of the alloys is included. Also in *Engineering* **131**, 498–500(1931). J. L. GREGG

Repairing pewter. A. EYLES. *Brass World* **27**, 27–8(1931).—The handling of pewter in the old days is outlined and practical notes are given for the reconditioning of old pewter vessels. In repairing old pewter vessels, dents must be removed and all surfaces must be perfectly clean. A good solder consists of Bi 50, Sn 25 and Pb 25%. Fluxes are rosin, Gallipoli oil, olive oil and a mixt. of rosin and olive oil. W. H. B.

A sand-cast test bar for specification purposes for aluminum alloy castings. S. L. ARCHBUTT. *1st Communications New Intern. Assoc. for Testing of Materials A*, 273–6 (1930).—Investigation into the use of a sand-cast bar prepd. in sand molds of special and simple type, with Y-alloy of widely varying gas content, is described. Density, machining and tensile tests on bars so prepd. are compared with corresponding values obtained from chill-cast bars of similar dimensions. The presence or absence of gas is clearly indicated in the results from the sand-cast bars, while relatively little effect is seen in the tests on chill-cast bars. E. J. C.

Magnesium alloy castings. E. PLAYER. *Metal Ind.* (London) **38**, 7–10, 31–2 (1931).—A review is given of the properties and foundry practice. The application of a special flux, Elrasal, which is to prevent the contamination of the metal is described, as well as the use of powd. S in the core material, to obtain clean castings. L. P.

The mechanical work of cutting and dressing rough castings. M. KURREIN *Z. Metallkunde* **22**, 382–6(1930).—A discussion is given of the evaluation of the mech. work performed, and its relation to design, by chisels, milling cutters, saws, grinding wheels and sand blast. The article is too detailed to permit adequate abstracting ROBERT F. MEHL

Some notes on a "burned-on" casting. L. W. BOLTON. *Bull. Brit. Cast Iron Research Assoc.* **1931**, No. 31, 342–3.—Bureau Report No. 68 describes physical and microscopic tests of a gray-iron casting 1.5 in. thick, which had an almost circular hole about 3 in. in diam. filled in by burning on new metal. R. RIMBACH

Some new facts of a chemical nature in the field of corrosion investigations and in the protection of metallurgical products against corrosion. JEAN COURNOT. *Bull. soc. chim.* **47**, 802–25(1930).—A review is given. Among the protective processes mentioned, the electroplating of Ni, Cd, Cr and parkerizing are discussed in greater detail LEPOLD PESSEL

Two years' progress in corrosion resistance. JOHN A. MATHEWS. *Paper Trade J.* **92**, No. 10, 57–8(1931).—A brief review is given of some of the causes of failures of 18–8 alloys, particularly in the sulfite industry. The latest metallurgical theories are given relative to C pptn., and the need for proper heat treatment of metals is stressed, as well as the chem. compn. of the alloys. Means of preventing metal embrittlement is indicated. A. PAPINEAU-COUTURE

The resistance of electrodeposits to corrosion, with special reference to cadmium and zinc. W. S. PATTERSON. *Metal Ind.* (London) **36**, 527–9, 579–82, 632(1930).—Of the 3 different types of corrosion of electrodeposits only the 1st is discussed: the corrosion of the coating metal considered as a continuous envelope sealing completely the metal it is protecting. The effects of impurities and of porosity of deposits upon corrosion were studied under a variety of conditions. Electrodeposited and hot-galvanized Zn are compared. Cd is regarded as an excellent coating for indoor work or for mild conditions of exposure, but for outdoor work where rain and atm. pollution

play an important part Cd fails and Zn is the more satisfactory and durable.
W. H. BOYNTON

Corrosion resistance of light alloys. H. SUTTON. *1st Communications New Intern. Assoc. for Testing of Materials A*, 304–8(1930).—A review of the more important work of British investigators. E. J. C.

The corrosion of aluminum casting alloys. R. STERNER-RAINER. *Z. Metallkunde* **22**, 357–61(1930).—The sensitivity of Al casting alloys toward corrosion is dependent upon the compn. and upon the corrosive agent. Contrary to the usual opinion that the corrosion of Al alloys cannot be improved by addns, it has been shown that all those substances which are effective in scpg. Fe and Si are effective in improving the corrosion resistance. It is not certain that a protective coating forms on Al alloys inhibiting further action, though the effect of small addns. of Sb and Bi furnish some support for such a belief. Other addns. decrease the corrosion resistance, especially Cu. The application of special alloys to special conditions is discussed. R. F. M.

Corrosion resistance of aluminum and its alloys. M. BOSSHARD. *1st Communications New Intern. Assoc. for Testing of Materials A*, 293–303(1930). —The great resistance which Al offers to the action of air, water and aq. salt solns. is due to the formation of a skin of oxide. Corrosion must be divided into 2 classes according to the way in which it occurs: (1) general corrosion, soly.; (2) local corrosion, formation of holes. General corrosion occurs only under the action of corrosive agents which dissolve the oxide. On the other hand, corrosive agents causing local corrosion have at first no oxide-dissolving qualities. The ability to dissolve the inert surface layer locally is a secondary effect of electrochem. action. The effect of impurities (Fe, Si, Cu, Mg, Zn and Mn) on the corrosion of Al is also discussed. E. J. C.

Studies of corrosion in aluminum and aluminum alloys under the microscope. H. RÖHRIG. *Z. Metallkunde* **22**, 362–4(1930); cf. *C. A.* **24**, 1835. —From microscopic studies reported R. concludes: (1) that deliberate or accidental inclusions are more noble to corrosive attack than the Al matrix; (2) that pores or voids offer assistance to the progress of corrosion; (3) that according to the nature of the attacking substance corrosion may proceed intergranularly or along strings of inclusions, or it may proceed concentrically from the starting point without regard for structure—the first is typified by the attack of sea water or sea water accelerated by H_2O_2, the second by boiling phenol or dil H_2SO_4. The purer the Al the fewer are the inclusions from which attack might start. Corrosion resistance may also be improved by heat treatment.
ROBERT F. MEHL

Corrosion of early Chinese bronzes. WM. F. COLLINS. *J. Inst. Metals*, Advance copy, No. **548**, 25 pp.(1931).— The probable mechanism of the formation of patina on early Chinese bronze is discussed in light of the corrosion studies made in England and the mechanism of mineral formation. S was probably not a factor in the corrosion of the Chinese bronzes. The ancient Chinese bronzes are unique in contg. appreciable quantities of Pb. The analyses of a large no. of these bronzes are given. The data also include the probable period of origin. J. L. GREGG

Corrosion of steel water pipes by stray electric currents. OTTO ROTHE. *Rev. brasil. chim.* **2**, 249–54(1930).—After a period of 1–2 years, pipes showed holes which from appearances and the presence of $FeCl_3$ at places not yet perforated made the deduction reasonable that the damage was caused by continuous elec. current. R. tested pipes at various points of the city and found that they were positively charged in relation to the soil around them; the p. d. from the voltage of the trolley car power lines had a max. of 10 v. It was possible to reproduce in the lab. funnel-shaped holes full of $FeCl_3$, similar to the ones in the city water pipes. The perforations occur where the asphalt protection is damaged and the elec. current is permitted to pass. A diagram is given. JOHN M. LADINO

Experiments with coal-fired pot-annealing furnaces. H. STÄBLER. *Stahl u. Eisen* 50, 381–91(1930).—An attempt has been made to elucidate some questions regarding annealing time, fuel consumption, choice of pot, etc., arising from an analysis of the details of operation of annealing furnaces in a no. of works. The max. and min. temps. within the heating stock, in a semi-gas-fired furnace capable of accommodating 5 pots, have been detd. as a function of the time. The annealing time, *i. e.*, the time required for the min. temp. within the material to reach the arbitrarily chosen value of 700°, is a linear function of the wt. of the charge (W) and is given by the equation $T = T_0 + KW$, where T_0 is the time required for the inner wall of the empty pot to reach 700°. The temp. difference, $t_{max.} - t_{min.}$, when $t_{min.} = 700°$, increases linearly with the wt. of the charge until the latter reaches about 1500 kg., when it passes through a max. and thereafter decreases. By suitably regulating the heating conditions, the char-

acteristic temp. curves ($t_{max.}$ and $t_{min.}$ as functions of the time) can be varied to correspond with any desired heat treatment of the material. The calcn. of the efficiency of the plant from the annealing time is discussed and illustrated by 1 or 2 examples.
B. C. A.

Press welding of iron. HANS ESSER. *Arch. Eisenhüttenw.* **4**, 199–206(1930).—E. dets. the relationship between the press weldability of pure Fe or Fe-C alloys and temp welding pressure, surface properties and grain size. Three dimensional diagrams are given, in which tensile strength is plotted against temp. and C content of press-welded Fe-C alloys. With pure Fe, the strength of the welded surface increases with temp. The smaller the grain size the more suitable is the material for welding, and at higher temps. the welding ability increases markedly with welding pressure. With increasing C content in pure Fe-C alloys, the temp. range suitable for press welding becomes lower

Recovering ore values on an adhesive surface. ROYER LUCKENBACH. U. S 1,792,544, Feb. 17. Candle tar with an oil thinner such as crude petroleum is used in sepg. ore constituents such as Au, Ag, Pt or other metals. Na silicate may be added to assist in sepn. of gang.

Apparatus for amalgamation of metal constituents in ores. EDGAR W. MYERS. U. S. 1,794,090, Feb. 24. Structural features.

Reducing iron from iron oxide ores. WM. W. PERCY. U. S. 1,792,507, Feb. 17. Preheated ore is charged into a reducing chamber and subjected to the reducing action of gases comprising CO and H, and after the gases have passed from the reducing chamber a portion of them is withdrawn. The temp. of the remaining gases is maintained, and they are caused to pass downward through a bed of incandescent C in a bottom-blown gas regenerator exterior to the reducing chamber and thence return into the bottom of the reduction zone at a temp. at which complete reduction of the Fe oxide will take place. App. is described.

Working up lead ores and waste. METALLGESELLSCHAFT A.-G. Ger. 514,679, April 29, 1927. Pb ores and waste contg. Pb, such as flue dust, are worked up in a completely rotatable cylinder furnace in which metals such as Zn, Cd and As are volatilized as oxides. The Pb is obtained, without the addn. of C, by the thermal reduction of $PbSO_4$ and PbS with production of SO_2 and SO_3. App. is described.

Working up ores containing zinc, lead and copper. ALBERT F. MEYERHOFER. Ger. 514,537, Dec. 24, 1924. A wet process for working up these ores consists in sepg. the Zn and Pb as sol. fluosilicates, leaving the Cu. The Zn and Pb fluosilicates are sepd. by fractional crystn. and worked up to obtain the metal with regeneration of HF. The Cu remains mostly as CuS and is worked up in the usual way. The detailed steps of the sepn. of the $ZnSiF_6$ and $PbSiF_6$ are given.

Treating zinciferous ores. A. FOLLIET and N. SAINDERICHIN. Brit. 337,636, Oct 19, 1929. Volatile metals in Zn-bearing ores contg. S are extd. by blowing air in 2 stages onto a thin traveling layer of the ore, first onto ore alone for desulfurization and then onto the hot roasted product together with reducing C. App. is described. Cf. *C. A.* **24**, 4499.

Tin from ores, etc. SOC. D'ÉLECTRO-CHIMIE, D'ÉLECTRO-MÉTALLURGIE ET DES ACIÉRIES ÉLECTRIQUES D'UGINE. Brit. 338,149, June 22, 1929. See Fr. 692,640 (*C. A.* **25**, 1481).

Separating and refining metals. HIRSCH, KUPFER- UND MESSINGWERKE, A.-G. (Cyrano Tama, inventor). Ger. 514,612, Aug. 31, 1928. Metals and metallic compds.

of differing m. p. are sepd. by placing them near the perforated bend of a tube and heating to the various fusing temps. of the metals or compds. by elec. induction.

Metal granules from molten metal. HARTSTOFF-METALL A.-G. Ger. 514,623, Dec. 6, 1928. Details of app. for atomizing the molten metal are described.

Floating metal powders. JOHN R. CAIN (to Richardson Co.). U. S. 1,794,585, March 3. A dry powd. metal such as Fe is treated with a volatile oily liquid such as benzene, and after the liquid is evapd. the powder is deposited on an aq. soln. of a metal salt such as a Cu salt soln., the metal of which will be replaced by the metal of the powder, and the resulting powder is consolidated into a foil on the surface of the soln. The product thus formed is suitable for integrating into foils by the action of an elec. current.

Treating impure lead containing copper and arsenic. JOHN B. SCHUETTENHELM (to Bunker Hill & Sullivan Mining & Concentrating Co.). U. S. 1,794,647, March 3. For recovering Cu and As in the form of dross from hot impure lead to purify the lead, the initial dross is skimmed off from a molten mass of the material and the material of the molten mass is caused to continuously circulate (as by the action of a propeller submerged in the bath, in a described app.) downwardly from and then upwardly to the surface of the bath. A charge of NH_4Cl is introduced into the circulating molten mass to sep. the Cu and As from the Pb so that the first two will rise by upward currents and gravity to the surface. The dross is skimmed off to recover the Cu and As from it while the mass is quiescent, the treatment with NH_4Cl and circulation of the material is repeated, and the temp. of the mass is gradually reduced as the process proceeds to freeze the Cu and As and facilitate their isolation by reason of their relatively higher m. ps. as compared with Pb, so that the dross will gradually become drier as the process proceeds.

Separation of gases such as sulfur dioxide from smelter fumes by adsorption under pressure. RUDOLPH L. HASCHE and WM. H. DARGAN (to American Smelting & Refining Co.). U. S. 1,794,377, March 3. An adsorbent material such as silica gel may be used and during "desorbing" sufficient heat is supplied to the material to balance the latent heat of vaporization of the gas and to maintain the temp. of the material substantially constant, so that the process is carried out substantially isothermally.

Ladle for melting metals (suitable for use in dental work). K. BRUDER. Brit. 338,063, Jan. 14, 1929. Structural features of a double-walled ladle the jacket of which may be filled with glycerol or other suitable liquid.

Molding sand mixture for use in casting iron, steel, brass, etc. ROY CROSS (to Silica Products Co.). U. S. 1,795,011, March 3. Inert material such as sand and clay is mixed with about 2.5-5% of bentonite treated to increase its jelling power (suitably by conjoint use of MgO, Ca aluminate, Ca silicate, portland cement or blast-furnace slag)

Binder for mold materials such as sand. MONROE S. CLAWSON. U. S. 1,794,588, March 3. Sawdust, resin and paraffin oil are used together.

Coating molds such as those for casting automobile engine pistons, etc. NELSON J. QUINN (to Metal Castings Holding Corp.). U. S. 1,794,536, March 3. Various mech. details are described for applying a liquid contg refractory material such as MgO to matrix surfaces from a nozzle first placed close to the surface to build up a relatively thick coating rapidly and then held at a greater distance from the surface to produce a surface coating which has the desired degree of porosity.

Ingot mold. EDWARD R. WILLIAMS (to Vulcan Mold and Iron Co.). U. S. 1,795,065, March 3. Ingot molds are made of cupola cast iron which contains less than 0.05% S and has a high resistance to cracking through sudden expansion.

Hot top for ingot molds. WM. H. RAMAGE (to Valley Mould & Iron Corp.). U. S. 1,792,868, Feb. 17.

Hot top for ingot molds. NIKLAS F. EGLER (to Insulated Top Co.). U. S 1,794,840, March 3.

Composite ingots. W. ALBERTS and F. STEIN. Brit. 338,092, Aug. 28, 1929. In casting ingots suitable for rolling into "Vignoles" rails, etc., the partition for sepg. the molten metals forming the ingot is made of practically pure iron and may be perforated or woven.

Ingots for producing non-porous articles such as rock drill pistons, etc. LOUIS G. FIRTH (to Firth-Sterling Steel Co.). U. S. 1,792,581, Feb. 17. Metal such as steel is cast into an ingot having a body portion and flanges extending from the latter, the flanges are longitudinally sepd. from the body portion, and products such as pistons, valve seats or valves are formed from the flanges.

Apparatus for die-casting metal articles. FRANZ F. MANTEI (to Friedrich J. Haas). U. S. 1,793,110, Feb. 17. Structural features.

Casting metals. HARRY ALBERT SCHWARTZ. Ger. 514,875, Mar. 4, 1924. App. for casting metals with cooling by a circulating liquid is described.

Casting slab ingots from deoxidized steel. EMIL GATHMANN. U. S. 1,793,314, Feb. 17. App. and various details for controlling solidification are described.

Casting blooms of aluminum. ELMER P. MCCLURE (to Aluminum Products Co.). U. S. 1,792,545, Feb. 17. Mech. features.

Casting aluminum alloy pistons, etc. FRITZ FEHRENBACH. U. S. 1,792,580, Feb. 17. Al is melted and Si is added in an amt. about 18% or somewhat more of the metal mixt., and to this mixt. are added particles of hard material such as Ag, Cu, B, Be, Zr, Mg, Ti, V, Mn, Mo or Cr to approx. 5% of the ultimate metal mixt. The molten mass is poured into a vertical mold and chilled, so that the hard metal particles are distributed over the surface of the casting.

Aluminum castings. THEODOR LAIBLE. Swiss 143,081, May 11, 1929. In making Al castings, NaCl, KCl, K_2SO_4, wood-charcoal dust, $Na_2B_4O_7.10H_2O$ and cryolite are added to the molten metal. These addns. prevent oxidation of the Al, adsorption of N, H or CO_2 and remove Fe, Si, etc., as scum.

Casting copper alloys. ARTHUR KIRCHHOF. Ger. 513,738, April 16, 1924. Thick castings of Cu alloys are produced by adding CuO to the molten metal just before casting in the proportions of 1 to 2 parts CuO to 50 parts of metal.

Casting "stainless steel" or similar alloys. W. E. MARTIN and J. A. BERLYN. Brit. 337,413, July 29, 1929. Structural details are described of sand molds which may be combined with chills and wire reënforcing in their walls.

Alloys of tungsten or molybdenum carbides. FRIED. KRUPP A.-G. (Hermann Voigtländer and Otto Kaufels, inventors). Ger. 514,728, May 3, 1928. See Brit. 310,876 (*C. A.* **24**, 584).

Ore-roasting muffled-retort furnace. HOWARD S. BAILEY and RAY A. BENNETT (Bailey to Bennett). U. S. 1,792,476, Feb 17.

Calcine-dust seal for ore-roasting furnaces. BENJAMIN G. CALL (to American Smelting and Refining Co.). U. S. 1,793,274, Feb. 17. Structural features.

Blast-furnace tuyère. E. POHL, A. WAGNER and GUTEHOFFNUNGSHÜTTE OBERHAUSEN A.-G. Brit. 338,130, May 10, 1929.

Tuyère for blast furnaces. HOLMES B. GRONINGER. U. S. 1,793,849, Feb. 24.

Drying air for furnace blasts. G. MALYOTH. Brit. 338,244, Aug. 28, 1929. See Ger. 515,216 (*C. A.* **25**, 1480).

Multi-trough hearth furnace for distilling metals such as zinc, mercury and cadmium. E. M. S. INDUSTRIAL PROCESSES, LTD., R. A. STOKES and E. G. L. ROBERTS. Brit. 337,471, Aug. 3, 1929. Structural features.

Metallurgical furnace suitable for annealing, etc. JOSEPH HARRINGTON (to Joseph Harrington Co.). U. S. 1,792,638, Feb. 17. Structural features.

Furnace suitable for continuous heating of metal sheet bars, slabs, billets, etc. FRANK J. WINDER (to Allegheny Steel Co.). U. S. 1,793,037, Feb. 17.

Furnace for heating metal billets and sheets. A. SMALLWOOD and J. FALLON. Brit. 337,362, June 25, 1929. Structural features.

Furnace for heat treatment of small articles in baskets or other containers. FRANK T. COPE (to Electric Furnace Co.). U. S. 1,794,151, Feb. 24.

Heating salt baths for heat treatment of metals. ARTHUR E. BELLIS. U. S 1,792,674, Feb. 17. A low-voltage a. c. is continuously passed directly through the bath material between an electrode immersed in the bath and the metal wall of the pot or container.

Heat treatment and quenching procedure for differential tempering of car wheels. JAMES C. DAVIS. U S. 1,794,445, March 3.

Heat treatment of loaded electrical conductors. V. E. LEGG (to Electrical Research Products, Inc.). Brit. 338,169, Nov. 24, 1928. In making Cu conductors loaded with magnetic material, with heat treatment, the Cu is first heated to about 1000° in the presence of a reducing agent such as charcoal (in a closed vessel in a resistance furnace) and afterward the loading material is applied, followed by further heat treatment and annealing. App. is described.

Apparatus for conveying materials such as metal bars or sheets through heat-treating furnaces. LEONARD LARSON (to Republic Steel Corp.). U. S. 1,793,940, Feb 24. Structural features.

Apparatus for annealing arched metal sheets. WM. E. WATKINS (to Copper Plate Sheet & Tube Co.). U. S. 1,794,659, March 3. Structural features.

Iron. WALTER G. CLARK. U. S. 1,792,967, Feb. 17. For producing a substantially C-free metal, iron is melted and heated air is blown through it until about 75% of the Fe is converted into oxide, the residual air is displaced with N and heated H is then blown through the mass until the oxide is reduced to metal and until the C content of the metal is reduced to the desired limit.

Cast iron. EDWARD R. WILLIAMS (to Vulcan Mold and Iron Co.). U. S. 1,793,268, Feb. 17. For making cast iron with a pearlitic structure, a charge of low Si and C contents is melted, the S content is reduced to below 0.05%, the molten metal is poured into a mold which is at room temp. and the casting is cooled normally without application of external heat.

Cast iron. MEEHANITE METAL CORP. Brit. 337,844, Aug. 13, 1929. Iron which has been produced by methods such as are described in Brit. 210,118 (*C. A.* **18**, 1640), Brit. 292,164 (*C. A.* **23**, 1382) and Brit. 312,126 (*C. A.* **24**, 819) is heat-treated by maintaining the casting at a temp. above the Ac_1 point (about 800°) for over 12 hrs. and then cooling (the first stage of cooling—as from about 900° to about 540°—being at a rate not exceeding about 10° per hr.).

Iron and iron alloys. T. D. YENSEN and N. A. ZIEGLER (to Associated Electrical Industries, Ltd.). Brit. 338,409, Jan. 18, 1929. For obtaining iron or alloys of Fe with Ni or Si, substantially free from C and O, there is added to the material such a quantity of either C or O that these elements are present in substantially equal atomic proportions and the material is melted while simultaneously removing the products of combustion as they are formed (as by evacuation or passing an inert gas through the furnace). C may be added as such and O may be added as free O, air or an Fe oxide or oxide of an alloying ingredient. The product may be allowed to solidify in a vacuum and cooled slowly from 900–1200° to normal temp. (with previous hot working if desired).

Heat treatment of iron and steel sheets. HERBERT M. COX and CARY M. SMITH (to Republic Steel Corp.). U. S. 1,792,573, Feb. 17. The sheets are heated to a temp. near the lower crit. point of the metal and maintained at this temp. for a time varying from $\frac{1}{2}$–6 min., then heated to a temp. above the upper crit. point of the metal, maintained at such temp. for 2–6 min., then cooled rapidly to a temp. below the lower crit. point of the metal, maintained at such temp. for 2 min. or less, reheated to a temp. near the lower crit. point of the metal, maintained at this temp. for 2–8 min. and then permitted to cool to atm. temp. This treatment gives the metal good drawing and stamping properties.

Protecting iron and steel from corrosion. A. FOLLIET and N. SAINDERICHIN. Brit. 337,562, Oct. 10, 1929. Articles of iron or steel are heated to 850–1050° in a mixt. comprising finely granulated Al free from Cu or Zn (the Al_2O_3 present as impurity not exceeding 6%), an inert material of high thermal cond. such as SiC free from graphite (this material constituting 40–60% of the volume of the mixt.), and 2–5% of one or more chlorides of non-ferrous metals alloyable with Fe, such as Cr, Ni or Mn. Double chlorides may be used and NH_4Cl 1.0–2.5% may also be added. A layer of an alloy of Fe, Al and the metal of the chloride used is formed on the articles.

Protecting iron and steel from corrosion. A. FOLLIET and N. SAINDERICHIN. Brit. 337,635, Nov. 28, 1929 A protective surface alloy is formed on iron or steel articles by embedding them in a mixt. of Al or Al-Mg alloy, oxides or oxidized ores of metals to be alloyed with the iron or steel (such as ilmenite, calcined pyrolusite, calcined garnierite or roasted nickeliferous pyrites, chrome Fe ore or wolframite), and 2–10% of one or more chlorides of the same metals. By heating in mixts. of this kind surface alloys are formed such as chrome-Ni steel, Ti-Mn steel or the like. Cf. *C. A.* **24**, 4254.

Open-hearth steel. ALEXANDER L. FEILD (to Republic Steel Corp.). U. S. 1,794,068, Feb. 24. A melted charge is refined in the presence of a slag in which a substantially constant percentage of Fe oxide is maintained by necessary tests and adjustments.

Open-hearth steel. GLENN E. HILLIARD. U. S. 1,793,442, Feb. 17. A molten bath of carbonized metal in the furnace is maintained in mobile condition and a strongly oxidizing flame is passed over the bath to effect oxidation of impurities. Finely divided scrap is introduced at such a rate of speed and in such volume that it is heated "nearly to molten condition" while approaching the surface of the bath but is not excessively oxidized by the flame.

Hardening steel by nitridation. F. KRUPP A.-G. Brit. 337,404, May 25, 1928. Nitridized articles of high resistance to stresses produced by high pressure or impact are made from steel free from Al and contg. Cr 1–20, C 0.25–3.0, W 0.5–3.0% and up to a total of 3% of Si, Mn, V and Mo (not more than 1% of any one of these). A

temp. of about 500° and a time of about 70 hrs. is suitable for the nitridation. Cf. *C. A.* **24**, 818.

Treating steel scrap in open-hearth furnaces. GLENN E. HILLIARD. U. S. 1,793,441, Feb. 17. Fine metal scrap is introduced into open-hearth furnaces in the form of a free-falling stream of such volume and at such rate that the occluded air will be consumed by the furnace gases while the scrap is moving into charged position.

Stainless steel. POLDIHÜTTE A.-G. Ger. 514,944, Sept. 2, 1923. An acid- and rust-proof steel contains Ni 20–25, C 0.2–0.8, Cr 9–27 and not more than 0.5% Mn or Si. Cf. *C. A.* **25**, 1792.

Alloys resistant to corrosion at high temperatures. R. A. HADFIELD. Brit. 337,893, Sept. 11, 1929. An alloy suitable for elec. furnace resistors contains Fe together with Cr 24–35, W 3–5, and Al 3–7%, the proportions of C, Mn and Si being low (suitably about 0.6, 0.3 and 0.6%, resp.).

Aluminum alloys. ALUMINIUM-INDUSTRIE A.-G. Brit. 337,922, Oct. 12, 1928. Elongation and bending and rolling capability of sheets, bands, wires, etc., of Al alloys of high tensile strength is improved by plating them with an Al alloy of lower tensile strength but of high elongation and good bending and rolling capability such as one contg. Mn 1–4, Mg 0.5–6% and up to 1% Sb, or one contg. Mn 0.5–2, Mg 0.3–1 and Si 0.5–2%, or up to 2% of Pb. Various details of manuf. are given.

Aluminum alloys. BIRMINGHAM ALUMINIUM CASTING (1903) CO., LTD., and P. PRITCHARD. Brit. 337,558, Oct. 9, 1929. Alloys comprising Al 94.5–96, Mg 3.5–5.0 and Mn 0.5% are made by melting Al and Mg and adding a melted Al-Mn alloy.

Aluminum alloys. ALUMINIUM-INDUSTRIE-A.-G. Swiss 142,629, Sept. 23, 1929. An alloy suitable for vehicle buffers contains Al, with Mg 0.3–1, Si 0.5–2, Mn 0.5–2 and Cu 3.5–5%.

Copper alloys. HANS KANZ. Swiss 141,610, Feb. 1, 1929. An alloy for grinding contains Zn 15–50%, up to 8% Sn, and Cu, with addn. of any of the metals Al, Fe, Mn, Ni, Sb, Pb or Si. The example mentions an alloy contg. Cu 62, Sn 4, Zn 30, Pb 2.5 and Ni 1.5%. Cf. *C. A.* **25**, 908.

Copper alloys containing also silicon, nickel, iron and zinc. EUGEN VADERS U. S. 1,792,944, Feb. 17. Casting alloys suitable for tools are formed mainly of Cu together with Si 1–4, Ni 1–5, Fe 4–6 and Zn 8–20%. Cf. *C. A.* **24**, 4503.

Iron alloys. WILLOUGHBY S. SMITH, HENRY J. GARNETT and JOHN A. HOLDEN Ger. 512,727, April 29, 1928. An alloy of high permeability for use in elec. circuits contains 4–10% Cr, 1–4% Al, 0.05% C and the rest Fe.

Iron alloys. VEREINIGTE STAHLWERKE A.-G. Brit. 338,071, Jan. 30, 1929. In the manuf. of Fe alloys, the rusting tendency of the alloy is detd. rapidly by first testing in the normal way the power of the material to withstand vibration stresses, and then ascertaining the power of the material to withstand vibration stresses while exposed to the corrosive action of water or moist air during the vibration test (the method being based on the fact that the rusting of steel proceeds in the same proportion as the resistance to fatigue stresses is reduced in the corrosion-fatigue test).

"Rustless" iron alloys. FREDERICK M. BECKET and JAMES H. CRITCHETT (to Electro Metallurgical Co.). U. S. 1,793,153, Feb. 17. In prepg. a low-C alloy of Fe and Cr of "rustless" character, the metal bath is side-blown with a blast contg. 50% or more free O to effect oxidation of constituents of the bath including C and a minor proportion only of the Cr and the temp. of the bath is raised to and maintained above 1600° solely by the exothermic reactions induced by the blowing operation, and the blowing is continued until the C content of the bath is reduced to 0.2% or less.

Iron-chromium alloys. SKODA WORKS, PLZEN. Brit. 337,767, April 18, 1929. Fe-Cr alloys contg. Cr 20–40 and C 0.2–3% contain also Ti 1–15 (preferably 1–5) and up to 15% of Al (preferably 5% or less).

Spongy metals. HENNING G. FLODIN. U. S. 1,792,532, Feb. 17. See Fr. 662,960 (*C. A.* **24**, 330).

Steel alloys containing chromium. F. KRUPP A.-G. Brit. 337,349, June 26, 1929. Austenitic Cr steel or Cr-Ni steel alloys contain also such a proportion of V or Ti or both as to enter into stable combination with the C dissolved by the austenitic basic mass and retain the alloy in austenitic form even when it is heated to 500–800°. The quantity of Ti or V is preferably at least twice that of the C.

Alloy steels. W. MATHESIUS and H. MATHESIUS. Brit. 337,715, March 16, 1929. In making Ti steel, previously decarburized and deoxidized liquid steel is passed from a ladle through a discharge brick in the bottom into a second ladle contg. pulverized or briquetted Ti thermic mixt.

Alloy steels. R. SERGESON. Brit. 338,315, Oct. 18, 1929. Alloy steel articles

which have been nitrided at about 460–560° for about 5–100 hrs. are reheated to between 590° and the lower crit. point of the core material (preferably about 650°) to decrease the brittleness and increase the toughness of the case. An example is given of the treatment as applied to a steel contg. C 0.32, Mn 0.56, Si 0.18, Cr 1.43, Mo 0.18 and Al 1.3%.

Alloy steels. J. T. Whiteley (to I. W. Heyman and S. L. Zavon, trading as Multi-Steel Co.). Brit. 337,919, Jan. 24, 1929. Alloys are formed contg. C 0.2–0.5% together with Mo 0.4–0.75, Cr 0.1–0.3, Si 0.2–0.5, Mn 0.5–1.0, Zr 0.5–1.5, Ti 0.1–0.3, Cu 0.5–0.9 and Ni 0.1–0.35%, and may be hardened by heating to about 925–950° and quenching.

Magnesium alloys. I. G. Farbenind. A.-G (Adolf Beck and Hugo Dibelka, inventors). Ger. 517,162, July 26, 1928 Addn. to 493,827 (*C. A.* **24**, 2713). The method for rendering the surface of Mg alloys non corrosive, described in 493,827, is modified by moistening the surface with dichromate soln. and drying, before carrying out the dichromate and HNO_3 treatment

Magnesium alloy suitable for pistons of internal-combustion engines. Walther Schmidt (to I. G. Farbenind A.-G.). U. S. 1,793,023, Feb. 17. Mg is alloyed with other metals such as Cu 15, Al 2 and Si 3%.

Strengthening magnesium and its alloys. I. G. Farbenind. A.-G. Brit. 337,706, March 11, 1929. The strength, especially the compression yield point, of Mg and its alloys is improved by hot working (suitably at 200–500°).

Silver alloys. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler. Ger. 514,772, Apr. 7, 1926. Alloys of Ag-Cu and Ag-Cu-Cd are improved by heating to glowing to a temp. just below that at which fusion commences and quenching. The process may be repeated with cold mech. working between the processes. In an example, a Cu-Ag alloy is heated to 730° and cooled in water.

Tungsten-carbide alloys. Joseph T. Terry. U. S. 1,792,943, Feb. 17. For controlling the C content of a W carbide alloy to prevent the formation of graphitic carbon, CaO is added to W and the mixt. is fused in a carbon crucible.

Steam and vacuum treatment system for drying spools of water-quenched wire. Charles B. Carr (to Western Elec. Co.). U. S. 1,793,275, Feb. 17. App. and various details of steam and vacuum treatments are described.

Pickling metals with acid solutions. Vanderveer Voorhees (to Standard Oil Oil Co. of Ind.). U. S. 1,793,146, Feb. 17. An acid soln. such as a 5–10% soln. of H_2SO_4, for use in pickling metals such as iron or steel, is prepd. with an addn. of org. substances recovered from sludge derived from a cracked petroleum distillate sol. in dil. H_2SO_4 but free from sludge substances sol. only in strong H_2SO_4. These substances serve to inhibit corrosion of the metal.

Pickling bath for steel plates, wire, etc. Edwin C. Wright (to National Tube Co.). U. S. 1,792,958, Feb. 17. A 5% H_2SO_4 soln. is used with an addn. of about 0.05% of a sulfonated product of coal-tar distillates b. 270–350° (other than anthracene oil), which serves as an inhibitor.

Purifying acid waste liquors such as those from pickling steel. John T. Travers (to Ohio Sanitary Engineering Corp.). U. S. 1,793,342, Feb. 17. Acid waste liquors contg. Fe salts are treated with a mixt. of lime and a solid waste product recovered from an alkali plant, the latter being in a quantity about 4 times that of the lime.

Case-hardening (nitriding) metal articles. John J. Egan (to Electro Metallurgical Co.). U. S. 1,793,309, Feb. 17. Articles such as iron alloys are heated in the presence of a nitriding agent such as NH_3 and at least one of the N oxides.

Local case-hardening of metals. Aubert & Duval Freres. Ger. 517,077, Nov. 18, 1927. The parts to be protected from nitridation are coated with a salt or a salt mixt., or with a glaze, enamel or the like, *e. g.*, with KCl or with a mixt. of $BaCl_2$ 2, KCl 1.5, $CaCl_2$ 1 and NaCl 1.25 parts, or with a mixt. of PbO 7, sand 2 and borax 1 part. The parts to be protected may be painted with water glass and the powd. salt, etc., then applied.

Sealing metals to insulating materials such as glass. N.-V. Philips' Gloeilampenfabrieken. Brit. 337,491, Aug. 12, 1929. In forming vacuum tubes, etc., comprising metal members such as rings or disks sealed to glass or the like, the metal at the point of union consists of an alloy preferably contg. 50–90% Fe together with one or more of the elements W, Mo, Ta, Cb, Co or Si, the coeff. of expansion of the metal being about the same as that of the insulating material with which it is to be united. Substances such as Cr, Al or Mg (preferably less than 5%) which form a coherent oxide film also may be added. Various structural details of manuf., etc., are described.

Apparatus for spraying metallic materials. Theo E. Bridger. Swiss 141,331,

Mar. 21, 1929. The metal is finely divided, centrifuged and subjected to an intermittent elec. current in an atm. of indifferent gas. Cf. *C. A.* **24**, 51.

Coating articles with vaporized or atomized metals, etc. KURT RICHTER. Ger. 517,419, Dec. 8, 1928. Low-pressure vaporization or cathodic atomization of the coating materials is effected in a flattened vessel having a relatively small vapor space through which a gas stream is led at a high velocity. Back-diffusion of the coating material is thus diminished.

Protective coatings on metals. A. ARENT. Brit. 338,221, Aug. 20, 1929. Metals such as iron or steel are provided with a protective coating or surface layer by treatment with a soln. of a chloride of As, Sb or Bi in a substantially non-aq. solvent such as C_6H_6, kerosene, acetone, AmOAc, EtOAc or their mixts. or with the vapor of such a soln. if a volatile chloride is used. The material may be preliminarily coated with Zn if desired, and a surface thus prepd. is suitable for further coating with paint, etc.

Coating and coloring aluminum alloys. A. PACZ. Brit. 338,204, Aug. 16, 1929. A colored protective coating is formed by treatment with a soln. contg. chromates or dichromates or both in quantity not exceeding 0.17% by wt. calcd. as CrO_3 and a comparatively large quantity of an alk. substance such as not less than 1.5% of Na_2CO_3. Various colors are produced depending on the compn. of the Al alloys, which may contain Si, Zn, Mn, Sb, Mo, Cu, Ag, Sn or W; small quantities of metal salts may be added to modify the coloring.

Coating iron or steel sheets, etc., with metals such as zinc-aluminum alloy. AMERICAN ROLLING MILL CO. Brit. 337,399, July 29, 1929. The metal to be coated is passed successively through a flux, a bath of molten Pb and a bath of molten Zn-Al alloy contg. 3–20% Al. App. and various details of operation are described. Cf. *C. A.* **25**, 909.

Apparatus (with squeezing rolls) for coating metal sheets with materials such as tin. EDMUND W. SHINN and ROBERT H. SCOTT. U. S. 1,794,093, Feb. 24. Structural features.

Determining the thickness of metal coatings such as tin and chromium. WESLEY A. RICHARDS and PAUL H. KRAMER. U. S. 1,792,606, Feb. 17. The coating is liberated by a stripping acid such as 37% HCl so that the salt of the coating will be in reduced condition. The reduced salt is measured by means of I soln. and starch as an indicator in the reaction reagent.

Cement mixture suitable for uniting metals. WM. R. CHAPIN. U. S. 1,793,156, Feb. 17. Silico-Mn 65 and powd. borax glass 1–10 are used with fine steel filings to make up about 100 parts total. U. S. 1,793,157 specifies silico-Mn 40, powd. Cu 25 powd. borax glass 1–10 and fine steel filings to make a total of about 100 parts. Cf. *C. A.* **24**, 5281.

Uniting iron with other materials such as tin or nickel. WM. H. SMITH. U. S. 1,793,757, Feb. 24. In forming alloys of Fe, finely divided iron such as "sponge iron" is assocd. with the other alloy elements such as Sn or Ni while still comparatively cold, and the assocd. materials are pressed into the general desired form so that they hold together by adhesion. They are then heated to a temp. somewhat below the m. p. of the iron to partly fuse the mass, heated up to alloying temp., and then subjected to pressure to effect final alloying and shaping.

Hard metal composition for cutting tools and dies. FLOYD C. KELLEY (to General Elec. Co.). U. S. 1,794,300, Feb. 24. A powd. mixt. consisting largely of W but contg. appreciable quantities of C and Co is treated with a small percentage of an alkyd resin and moistened with a solvent such as acetone. The material is pressed, heated sufficiently to vaporize the solvent and resin, further heated to sintering temp. and subjected to pressing while highly heated.

Use of tungsten carbide for making hard tough metal products. SAMUEL L. HOYT (to General Elec. Co.). U. S. 1,794,229, Feb. 24. Powd. W carbide is mixed with a cementing metal such as Co and the mixt. is pressed into the desired form to make tool bits or other articles, sintered into a hard mass and then subjected to pressure while subjected to a sintering temp. Cf. *C. A.* **24**, 5016.

Apparatus for flexing metal wire or strips such as iron or steel while immersed in a liquid such as sulfuric acid to remove surface impurities. FRANK M. DORSEY (to Madsenell Corp.). U. S. 1,793,914, Feb. 24.

Filaments of material such as metals. GEORGE F. TAYLOR (to Baker & Co.). U. S. 1,793,529, Feb. 24. Material such as a metal of low or high m. p. sheathed with borax, glass or quartz is drawn into a cored filament while heated to render it sufficiently fluent and the cored filament is solidified close enough to the heated substance so that the substance will flow to the point of soldifying. App. is described.

Indented metal foil. ALUMINIUMWERKE A.-G., RORSCHACH. Brit. 337,716, May 24, 1929. Metal foils with deep indentations are formed by passing smooth foil through goffering rollers together with paper which is subsequently burned away in an annealing process (suitably at 300–550°).

Metal bearings. HENRY L. BARTON (to General Motors Research Corp.). U. S. 1,792,565, Feb. 17. Powd. bearing metal such as finely comminuted Babbitt alloy is placed in a bearing back and subjected to pressure to cause it to unite with the back in good heat-conducting relation.

Magnetic material comprising nickel, chromium, cobalt and iron. GUSTAF W. ELMEN (to Bell Telephone Laboratories, Inc.). U. S. 1,792,483, Feb. 17. A material comprising Ni 10–80 and Co 5–80, Fe between 9 and 50% of the entire Ni-Fe-Co content and Cr up to 12% is heat-treated to give it good magnetic properties with small magnetizing forces, and is suitable for use in making loading coils of signaling systems, etc. Cf. *C. A.* **25**, 678.

Metal for use in spark-plug manufacture. A. A. POSTNIKOFF and E. P. ZEREKIDZE. Brit. 337,889, Sept. 7, 1929. The metal surfaces exposed to the combustion gases are coated with Cr or a Cr alloy to a thickness of 0.0001–0.00025 in.

Cutting elements for paper-making engines. CLARENCE W. NOBLE (to Noble and Wood Machine Co.). U. S. 1,792,546, Feb. 17. The side portions of cutting edges are formed of relatively hard metal such as Cr and the central portions of softer metal such as steel.

Welding electrode. JOHN G. RITTER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,794,983, March 3. Welding electrodes formed of an alloy of Fe 65–45%, minor impurities and Ni 35–55% produce welded joints substantially free from residual stresses by deposition at a temp. near or below its low annealing temp. Various details of temps. for working with varying compns. of alloy are described.

Arc electrodes for welding. J. H. AITCHISON, H. BULL and L. JOHNSON. Brit. 337,589, Oct. 25, 1929. Billets are formed of one or more metals of an alloy to be welded (such as Cr steel for welding "stainless steel") and are provided with one or more longitudinal cores or coverings of the other metal or metals of the alloy to be welded (such as Ni), and the composite billet is worked into composite electrodes by rolling, forging or drawing. Various details and modifications of manuf. and compns. for electrodes are given.

Electrode for metal deposition by the electric arc process. ARTHUR P. STROHMENGER (to Quasi-Arc, Inc.). U. S. 1,794,042, Feb. 24. An electrode is formed with a flux-forming covering and a ferrous core contg. a quantity of Mn dependent on its diam. and varying inversely as the diam. from 2.25% to 4.0% for cross sections of electrode cores from 0.042 to 0.005 sq. in. This proportion of Mn avoids a brittle zone in the deposit. Cf. *C. A.* **24**, 52.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

The determination of the empirical formula of a hydrocarbon. EDWARD W. WASHBURN. *Bur. Standards J. Research* **5**, 867–90(1930).—The precision aspects are discussed of the problem of detg. the mol. wts. and H content of a hydrocarbon, and of combining the results so as to obtain the empirical formula. "A detn. of the Br (or other) addn. no. may, in some instances, be substituted for the mol.-wt. detn. or for the combustion analysis, or may be utilized to decrease the accuracy which would otherwise be required in either or both of these detns." By following the lab. procedure outlined it should be possible to det. the empirical formula of any pure hydrocarbon contg. not more than 100 C atoms. R. E. SCHAAD

Formation of carbon tetrachloride from the elements. ALFRED STOCK, HERMANN LUX AND WERNER WUSTROW. *Z. anorg. allgem. Chem.* **195**, 149–57(1931).—Specially prepd. C made from filter paper and well outgassed was used. This prepn. was placed in a quartz tube in a furnace at either 400° or 500° (only 2 temps. were studied) and measured amts. of Cl_2 were admitted; the contents of the tube were analyzed at various periods. CCl_4, HCl and traces of CO_2 were found. Heating periods were for as long as 90 hrs. Activation of the C was attempted. The effect of HCl on the reaction vessel was also studied; in 70 hrs. 3.7 cc. HCl was quantitatively converted into H_2O. Cl_2 had practically no effect on the glass. WILLIAM E. VAUGHAN

Pentane. C. R. NOLLER. *Org. Syntheses* **XI**, 84–6(1931).—Details are given for

the prepn. of C_6H_{12} from $Me(CH_2)_2CHBrMe$ through the Grignard reaction; yield, 50–3%. C. J. West

Carotene. III. Hydrogenation and optical properties of carotene and its hydrogenated derivatives. James H. C. Smith. *J. Biol. Chem.* **90**, 597–605(1931); cf. *C. A.* **24**, 3794.—By reduction of carotene (I) in Et_2O with Al-Hg, filtering and drying *in vacuo*, *dihydrocarotene*, $C_{40}H_{58}$, was obtained as a noncrystallizable orange compd., $[\alpha]_D^{18}$ 41.9° (Et_2O), 38.0° (EtOH). I had $[\alpha]_D^{18}$ −63° ± 17% (CS_2). The degree of hydrogenation by Adams' catalyst varied with the amt. of catalyst. With 5.2 g. I in cyclohexane and 0.126 g. catalyst, 9 mols. H_2 was absorbed to give a colorless oil, $C_{40}H_{74}$, *octadecahydrocarotene* (II), $[\alpha]_D^{14}$ 7.56° (CS_2), $d_4^{29.2}$ 0.8828, d_4^{80} 0.8524, $n^t{}_D$ 1.4962 − 0.000367 *t*, M_D 180.3 (calcd. for straight chain 178.2). With 0.85 g. I and 1.84 g. catalyst, 10.23 mols. H_2 was absorbed to give a clear viscous oil, $C_{40}H_{76}$, *eicosahydrocarotene* (III), $b_{0.0001}$ 206°, $[\alpha]_D^{20}$ 0.337°, $n_D^{24.2}$ 1.4821, $d_4^{24.2}$ 0.8748, M_D 181.42 (calcd. for straight chain 180.32). From the low mol. exaltations of II and III the presence of the cyclopropane rings is deduced. The steady decrease in rotation on hydrogenation shows that the 2 linkages hardest to sat. are those producing asymmetry. The 2 bonds reducible by Al-Hg are probably attached to rings (Kuhn and Winterstein, *C. A.* **23**, 4682). A structure of 9 conjugated double bonds, conjugated further with 2 cyclopropane rings, is assigned to I; this agrees with the formula of Karrer, *et al.* (*C. A.* **25**, 519). K. V. Thimann

A method for the preparation of substituted acetylenic hydrocarbons. René Truchet. *Compt. rend.* **191**, 854–6(1930).—Methylacetylenes are satisfactorily prepd. by treating a Na acetylide with Me_2SO_4, $PhSO_3Me$ or *p*-$MeC_6H_4SO_3Me$. The reaction with aromatic SO_3H acids appears to be perfectly general, 45–60% yields resulting from treating RC : CNa with various sulfonic esters for 3 hrs. at 80°, decompg. with H_2O, extg. with Et_2O, drying over $CaCl_2$, distg. *in vacuo* and redistg. at atm. pressure. C_6H_{11}-C : CNa (I) plus *p*-$MeC_6H_4SO_3Et$ (II) gave 45% of *3-nonine*, b. 155–7°, d_{20} 0.763, n_{20} 1.429, M. R. 41.9 (calcd. 41.77). $C_6H_{11}C$: CNa with II gave *3-decine* (47% yield), b. 175–6°, d_{21} 0.765, n_{21} 1.433, M. R. 46.6 (calcd. 46.4). I with *p*-$MeC_6H_4SO_3Bu$ gave *5 hendecine* (60% yield), b. 195–6°, d_{20} 0.785, n_{20} 1.437, M. R. 52.0 (calcd. 51.1). I with $PhSO_3C_7H_7$ gave *amylallylacetylene*, b_{12} 74.5–5.5°, d_{20} 0.788, n_{20} 1.445, M.R. 46.2 (calcd. 46). By-products of these reactions may be ethers produced by heating the sulfonic esters, alcs. from sapon. of the esters or 1-chloroacetylenic hydrocarbons resulting from the presence of small quantities of sulfonyl chloride. These chloroacetylenes are especially hard to remove so care should be taken to use esters contg. none of the chloride. C. H. P.

Preparation of chlorinated acetylene derivatives. Stephan Langguth. *Chimie & industrie* **25**, 22–5(1931).— Directions are given for the prepn. of $SbCl_5$, $SbCl_6$, $C_2H_2Cl_4$, $C_2H_2Cl_2$, CCl_2:CHCl and $(PhNH)_2C$:CHNHPh. A. Papineau-Couture

The higher alcohols of the paraffin series and their technical significance. Schrauth *Chem.-Ztg.* **55**, 3, 17–8(1931).—The higher alcs. are now available, made by reduction of the corresponding acids. Various uses are indicated, chiefly as the sulfuric and sulfonic acid derivs. in *medicine* and as *emulsifying agents;* as esters in *perfumery* and as *waxes.* T. H. Chilton

Some α,α-dichloro and α,α-diethoxy tertiary alcohols and the hydroxy aldehydes derived from them. A. Avy. *Bull. soc. chim.* [4], **49**, 12–8(1931).—The general problem of prepg. α-HO aldehydes of the type $R_2C(OH)CHO$ (I) from $R_2C(OH)CHCl_2$ (II) and $R_2C(OH)CH(OEt)_2$ (III) was investigated. Type II compds. were prepd. by treating Cl_2CHCO_2Et (IV) with the suitable organomagnesium bromide since the bromides gave better yields than the iodides used heretofore. IV was obtained in 90% yield by boiling for 6 hrs. 100 g. Cl_2CHCO_2H with 300 g. abs. alc. in the presence of 3 cc H_2SO_4. $Me_2C(OH)CHCl_2$, obtained in 74% yield, m. 8°, b_5 38°, b_{10} 52°, d_4^0 1.2507, d_4^{19} 1.2363, n_D^{19} 1.4598. $Et_2C(OH)CHCl_2$ (V), obtained in 70% yield, b_{14} 76°, d_4^0 1.1999, d_4^{21} 1.1750, n_D^{21} 1.47102. $EtCOCHCl_2$ is obtained in the proportion of 12 g. to 100 g V, in the prepn. of V. $Pr_2C(OH)CHCl_2$ and $Bu_2C(OH)CHCl_2$ were obtained by this method in very poor yield (15%) and in an impure state. $Ph_2C(OH)CHCl_2$ (VI), obtained as chief product along with Ph_2 and an unidentified very slightly sol. compd., b_5 200°, crystals from a mixt. of Et_2O and petr. ether, m. 95–6°. $PhCH_2MgBr$ acted on IV to form dibenzyl as the only isolated product. Type III compds. were prepd. more

Type III compds. are more sensitive to the action of mineral acids than type [illegible] $Me_2C(OH)CH(OEt)_2$ (VII), obtained in 70% yield, b_{19} 75°, d_4^0 0.9478, d_4^{24} 0.9277, n_D^{24} 1.41109. $Et_2C(OH)CH(OEt)_2$ (VIII), obtained in 83% yield, b_{18} 95°, d_4^0 0.9409, d_4^{21}

0.9230, n_D^{21} 1.4255. $Pr_2C(OH)CH(OEt)_2$ (**IX**), obtained in 70% yield, b_6 98°, d_4^0 0.9261, d_4^{22} 0.9073, n_D^{22} 1.4258. $Bu_2C(OH)CH(OEt)_2$ (**X**), obtained in 70% yield, b_3 101°, b_7 122°, d_4^0 0.9167, d_4^{20} 0.9001, n_D^{20} 1.4315. $Ph_2C(OH)CH(OEt)_2$ (**XI**), obtained in 55% yield, b_4 170°, m. 125°. Attempts to prep. type I compds. by heating type II compds. with $CaCO_3$ suspended in water, Na_2CO_3, PbO and water for various periods at various temps. never resulted in the isolation of type I compds. though small amounts of impure $Et_2C(OH)CHO$ (**XII**) were obtained by refluxing 72 g. V for 36 hrs. with 300 cc. water and 50 g. $CaCO_3$, extg. with ether, drying and fractionating, when 15 g. of a yellow oil b_{15} 55–7° was obtained which gave a semicarbazone (**XIII**) of **XII**, m. 204–5°. Hydrolysis of **XIII** with aq. $(CO_2H)_2$ gave a liquid b_{13} 28°; semicarbazone m. 210°; oxime m. 62°. Analysis indicates these compds. are derived from **XII** after elimination of 1 mol. of water. Hydrolysis of type III compds. with warm dil. HCl yielded type I compds., but with cold concd. HCl intermediate compds. of type **XIV** apparently resulted according to the scheme: $2R_2C(OH)CH(OEt)_2 \longrightarrow R_2C(OH)CH(OH)OEt + R_2C(OH)CHO \longrightarrow O.CR_2.CH(OEt).O.CHC(OH)R_2$ (**XIV**) + H_2O. Type **XIV** compds. on further hydrolysis yield type I compds. When 10 g. of **VII**, 2.5 g. water and 3.5 g. concd. HCl stood 24 hrs. in a flask and were then extd. with ether there was obtained 5 g. of a sirupy liquid, b_{12} 105°, whose properties and analysis correspond to those predicted for the corresponding type **XIV** compd. Warm dil. HCl on **VII** gave a high-boiling material not identified. Hydrolysis of 9 g. **VIII** with cold dil. HCl gave 5 g. liquid, b_6 114–5°, which did not give a semicarbazone and has strong reducing properties and is probably a polymer of $Et_2C(OH)CHO$ (**XV**). Warm dil. HCl on **VIII** gives 65% of impure **XV**, characterized by its semicarbazone as a type II compd. Hydrolysis of 7 g. **IX** with cold HCl gave 3 g. of an apparently type **XIV** compd., crystals from ether, m. 87°. Hydrolysis of **X** with cold HCl apparently produces (from analysis and mol.-wt. detn.) a type **XIV** compd. (**XVI**), m. 90–1°. **XVI** (0.9 g.), distd. with 20 cc. water and 2 cc. HCl, produces 0.7 g. oil, b_6 94–7°, d_0 0.920, d_{22} 0.9040, n_D^{22} 1.4379, whose mol wt., analysis and analysis of its semicarbazone, m. 141–2°, prove it to be pure $Bu_2C(OH)CHO$.

ODEN E. SHEPPARD

The use of calcium chloride in the dehydration of alcohol. K. B. EDWARDS AND R. LACEY. *J. Soc. Chem. Ind.* **49**, 422T(1930).—Alc. residues are concd. to 80% by distn. Then 20 g. of fused $CaCl_2$ per 100 cc. alc. is added. Distn. yields 78% of 95.5% alc. and 8% of "tails." The alc. remaining with $CaCl_2$ in the still is recovered by adding water and distg. Simple tests for the concn. of the alc. have been worked out; they depend on the miscibility of one drop of alc. in 5 cc. of various solvents. Kerosene, miscible when the concn. is 99.35%; white spirit, 98.3%; com. xylene, 97.4%; permanent cloudiness with 3 drops of 97.2%. The tests are to be carried out between 15° and 18°.

ALBERT L. HENNE

Triethylcarbinol. W. W. MOYER AND C. S. MARVEL. *Org. Syntheses* **XI**, 98–100 (1931).—Detailed directions are given for the prepn. of Et_3COH from EtMgBr and $(EtO)_2CO$; the yield is 82–8%. The following were prepd. by the use of the proper Grignard reagent and $(EtO)_2CO$: Pr_3COH 75, Bu_3COH 84, Am_3COH 75 and $(C_7H_{15})_3COH$ 72%.

C. J. WEST

Aliphatic ethers. HERBERT HENSTOCK. *J. Chem. Soc.* **1931**, 371–2.—PrI and iso-BuONa, shaken 12 hrs. at 10° and then heated 1 hr. at 100°, give 67.2% of *Pr iso-Bu ether*, b_{720} 106°, d^{15} 0.7549, $n_{5461}^{24.9}$ 1.3852. *iso-Pr Bu ether*, b_{738} 108°, d^{15} 0.7594, $n_{5461}^{24.9}$ 1.3889 (72.4% yield). iso-BuOPr, BuOPr, iso-PrOPr, EtOPr, MeOPr, iso-BuOBu, iso-PrOBu, EtOBu, MeOBu, iso-PrOEt, iso-PrOMe, iso-BuOEt and iso-BuOMe, heated with Na-K in N at 190–200° for 24–100 hrs., are unchanged; it thus appears that in ethers the bonds between the simple alkyl radicals and the O atom are stronger than the corresponding bonds holding heavier radicals contg. highly branched chains.

C. J. WEST

Syntheses with β,β′-dichlorodiethyl ether. II. Heterocyclic compounds containing two members of the oxygen group in the ring. 1,4-Selenoxane and its derivatives. CHARLES S. GIBSON AND JOHN D. A. JOHNSON. *J. Chem. Soc.* 1930, 266–72; *Chemistry & Industry* **49**, 896(1930); cf. *C. A.* **25**, 681.—$(ClCH_2CH_2)_2O$ or $(ICH_2CH_2)_2O$ and Na_2Se in water, heated 4.5 hrs. while H is passed through the mixt. give *1,4-selenoxane* (**I**), purified through the dibromide which is obtained in 33–40% yields; 164 g. dibromide gives 60 g pure **I**; I b_{22} 66°, b_{26} 69.5°, b_{768} 167.5–8.5°, m. —21.5°, n_D^{20} 1.5480, d_4^{16} 1.575, $d_4^t = 1.597 - 0.00135t$; γ^{17} 42.08, $\gamma^{28.5}$ 40.80, $\gamma^{35.5}$ 39.75, γ^{44} 38.67 dynes/cm.; I is a colorless liquid with penetrating but not unpleasant odor; it is volatile in CCl_4 vapors;

$SnCl_4$ gives a cryst. compd. decompd. by atm. moisture; I and HNO_3 (d. 1.42) give a deep red soln. from which the *hydroxynitrate* sepd. on cooling; it decomps. 140–1° and detonates on heating in a sealed tube over a small flame; its aq. soln. gives the dibromide with HBr in the cold. I and Cl in CCl_4 give the *dichloride*, m. 127–9° (decompn.); Br in CCl_4 gives the *dibromide*, yellow, m. 132° (decompn.); the aq. soln. gives no ppt on cooling but HBr ppts. the dibromide; *diiodide*, violet, m. 106–7°. I and MeI in abs. EtOH for 5 hrs. or I and MeI for 2 hrs. give the *methiodide*, m. 171°. I and $HgCl_2$ in EtOH give the *mercurichloride*, m. 179°; *chloroaurate*, golden yellow, decomps. 142–4°; *chloroplatinate*, orange-yellow, m. 149° (decompn.). The dibromide and moist Ag_2O give a highly hygroscopic oil, which gives the hydroxynitrate with HNO_3. The dibromide and dry NH_3 in C_6H_6 give the *compd.* $C_4H_{14}ON_2Br_2Se$, begins to decomp. 93° and turns brownish yellow 130°; it is decompd. by water; similar compds. were formed with pyridine, piperidine and $PhNH_2$. The coördination compd. of the dibromide with $C_2H_4(NH_2)_2$ yielded $C_2H_4(NH_2)_2.2HBr$ on treatment with aq. EtOH. The parachor, 245.2, confirms the value of 62.5 for the at. parachor of Se. C. J. West

Formation of sulfonium chlorides and of unsaturated substances by the action of water and of aqueous alcoholic potash on β,β′-dichlorodiethyl sulfide. John S. H Davies and Albert E. Oxford. *J. Chem. Soc.* **1931**, 224–36.—The hydrolysis of $S(C_2H_4Cl)_2$ (I) is generally assumed to occur in 2 stages: $I + H_2O \longrightarrow ClC_2H_4SC_2H_4OH$ (II) + HCl; $II + H_2O \longrightarrow S(C_2H_4OH)_2$ (III) + HCl. It is probable that II has not been isolated; attempts to prep. II from HOC_2H_4SH and ClC_2H_4Cl or from ClC_2H_4SH and $(CH_2)_2O$ failed. II, evapd. in the min. quantity of water at a low temp. under diminished pressure gives a sirup, insol. in $CHCl_3$ and Me_2CO and hence not II or III, but readily sol. in cold H_2O to give a soln. contg. much Cl ion. I yields a *diphenylurea*, m **128.5–9.5°**; the methiodide is a viscous red oil; the *p-toluenesulfilimine* formed from chloramine-T, m. 86–7°. III and HOC_2H_4Cl, heated on the water bath for 13 hrs., give *tri-β-hydroxyethylsulfonium chloride* $(HOC_2H_4)_3SCl$, m. 125–6°; the yield is largest with 3 mols. ClC_2H_4OH; it develops no acidity when dissolved in water and the Cl content can be estd. volumetrically; it is sol. in concd. HCl but no I is formed on prolonged boiling. III and I, heated 6 hrs. at 65–75°, give *sulfidobis-β-hydroxydiethyl sulfide 1,3-di-β-hydroxyethochloride*, $Cl(HOC_2H_4)_2SC_2H_4SC_2H_4S(C_2H_4OH)_2Cl$, m. 101.5–3°; with HCl at 100° only I is formed; the *chloroplatinate*, yellow, amorphous, m. 133–4°. This explains why II has not been isolated by the hydrolysis of I, for, even if it were formed momentarily, it might unite with itself and most certainly would combine with III to form sulfonium chlorides. $HOC_2H_4SC_2H_4SC_2H_4OH$ and ClC_2H_4OH, heated at 100° for 14 hrs., give 2 sulfonium chlorides, probably IV and *sulfidobis-β-hydroxydiethyl sulfide 1,2-di-β-hydroxyethochloride*, m. 120–1.5°. $HOC_2H_4SC_2H_4SC_2H_4OH$ and HOC_2H_4Cl heated on the water bath for 8 hrs., or HOC_2H_4Cl and 1,4-dithiane, heated at 100° for 28 hrs., give *1,4-dithiane 1-β-hydroxyethochloride* (IV), m. 175°; *mercurichloride*, m. 95–6°. Passing dry HCl into III at 100–6° gives 56% I and 44% of *oxidobis-β-chloroethyl sulfide*, b_1 152°; the latter and PhOH with EtONa give the *phenoxy deriv.*, m. 55–7°. Hydrolysis of I with 2.25 vols. water gives IV, but this was not found when 6 vols. water was used. The sirup obtained with 4 mols. water, heated with concd HCl 40 min. at 100°, gives I and a small quantity of $C_2H_4(SC_2H_4Cl)_2$. If 10 vols. HCl is used, I is the sole product. III and 2 mols. HCl in 2.5 vols. water, heated 5 hrs., give IV and other sulfonium chlorides. Hydrolysis of 1 mol. I with 4 mols. 20% EtOH-KOH (EtOH:H_2O = 4:1) gives a mixt. of divinyl sulfide, b. 85° (*sulfilimine*, m. 91–3°), *β-ethoxyethyl vinyl sulfide*, b_8 65°, d_4^{20} 0.9532, camphor-like odor (*mercurichloride*, m. 152–3°), $S(C_2H_4OEt)_2$, b_4 101–2° and some $EtOC_2H_4SC_2H_4OH$, b_4 117.5°. With 1 mol EtOH-KOH, there was isolated *β-chloroethyl vinyl sulfide*, b_{80} 71–2° (*sulfilimine*, m. 101.5–3°; mercurichloride, amorphous, decomps. about 150°); with HCl this yields *α,β′-dichlorodiethyl sulfide*, b_9 68–9°. C. J. West

Heptylamine. W. H. Lycan, S. V. Puntambeker and C. S. Marvel. *Org. Syntheses* **XI**, 58–60(1931).—Reduction of $Me(CH_2)_5CH:NOH$ with EtOH and Na gives 60–73% of $Me(CH_2)_6NH_2$, b. 152–7°. By use of the same method the following may be obtained: $BuNH_2$, in 50–60% yields, *sec*-$BuNH_2$ and cyclohexylamine. C. J. West

Acrolein acetal. E. J. Witzemann, Wm. Lloyd Evans, Henry Hass and E. F. Schroeder. *Org. Syntheses* **XI**, 1–2(1931).—$ClCH_2CH_2CH(OEt)_2$ (167 g.) and 340 g powd. KOH, heated at 210–20°, give 75% of $CH_2:CHCH(OEt)_2$, b. 122–6°. Fe retorts should be used when many runs are to be made. C. J. West

β-Chloropropionaldehyde acetal. E. J. Witzemann, Wm. Lloyd Evans, Henry Hass and E. F. Schroeder. *Org. Syntheses* **XI**, 26–7(1931).—EtOH-HCl, satd. at 0°

and treated with CH_2:CHCHO at about 0°, gives 34% of $ClCH_2CH_2CH(OEt)_2$, b_8 58–62°. C. J. WEST

Heptaldoxime. E. W. BOUSQUET. *Org. Syntheses* XI, 54–6(1931).—$Me(CH_2)_5CHO$, $NH_2OH.HCl$ and Na_2CO_3 give 81–93% of $Me(CH_2)_5CH$:NOH. Cyclohexanone oxime is obtained in the same manner. C. J. WEST

Fatty acid distillation. A comparison of intermittent and continuous operation. OTTO KREBS. *Teer u. Bitumen* **28**, 421–4, 440–3(1930).—Batch distn. with superheated steam and continuous distn. under reduced pressure (60 mm.) are described with some detail and the economics of the 2 methods compared. Vacuum distn. permits an easy sepn. of $C_{15}H_{31}CO_2H$, b_{60} 255°. $C_{17}H_{33}CO_2H$ boils only slightly lower than $C_{17}H_{35}CO_2H$; their sepn., therefore, requires a very efficient fractionation column. K. H. ENGEL

Addition of alkali alcoholates to acid esters. IV. Addition of sodium ethylate to formic ester. F. ADICKES (WITH A. WÄCHTEROWITZ, H. DU MONT AND O. LÜCKER). *Ber.* **63B**, 3012–27(1930); cf. *C. A.* **21**, 1628; Scheibler, *C. A.* **20**, 2824; **21**, 1795.—S. says in his 1st paper that NaOCOEt (I) is obtained quantitatively according to the equation $HCO_2Et + NaOEt = HC(ONa)(OEt)_2$ (II) = I + EtOH by letting NaOEt and 1 mol. HCO_2Et stand in Et_2O 16 hrs., evapg. *in vacuo*, adding another 0.5 mol. HCO_2Et, letting stand again and once more evapg. off the excess of HCO_2Et, along with the EtOH formed, *in vacuo*. A. showed that the product was not I (*C. A.* **21**, 1628) but the conclusion drawn from analyses of the apparently homogeneous substance that it was quite pure II has now been found to have been incorrect. Contrary to S.'s statement, a great part of the HCO_2Et used is decompd. into CO and EtOH and a part of the EtONa is not added at all, so that the product consists in great part of NaOEt with more or less EtOH of crystn. (around 30%) and some HCO_2Na (8%) and can, therefore, contain only about 10–20% II. With such a product, the Zeisel EtO detn. can be carried out only with certain precautions in a modified app.; the far too low results obtained in the usual Meyer app. had led to an erroneous interpretation, and, moreover, the apparent absorption of 1 mol. HCO_2Et by the NaOEt (calcd. from the amt. of HCO_2Et used and that recovered from the Et_2O and EtOH vapors drawn off) was merely due to the aforesaid decompn. of the HCO_2Et. According to S.'s 2nd paper, I is prepd. by splitting EtOH off from the (assumedly almost pure) II at 40° and completing the reaction by repeated treatment with HCO_2Et and splitting off of EtOH. No proof (by detn. of the CO) is given of the decompn. $I + H_2O = NaOH + CO + EtOH$ which S. describes as characteristic but which A. has never observed. The apparent success of the new method of prepn. is due to the fact that the temp. is raised by the "vigorous reaction" which takes place; the decompn. of the HCO_2Et, which is slow at room temp., is now very rapid and the product is not I but NaOEt, more or less free of EtOH of crystn., depending on the length of the last heating *in vacuo*. In both methods of prepn. the HCO_2H present in the product (as the acid and as HCO_2Et) can be detd. by reduction of $HgCl_2$ or by back titration after sapon. with excess of hot alkali. The HCO_2H is present partly as HCO_2Na because ordinary abs. alc. and HCO_2Et not dried over P_2O_5 are used in the process. This is also shown by analysis of the salt mixt. obtained by passing CO_2 into the Et_2O suspension of the supposed I; the HCO_2Na remains unchanged, the NaOEt is converted into $EtOCO_2Na$ and a part of the total HCO_2H is recovered as HCO_2Et, presumably from II, for I could not regenerate HCO_2Et with CO_2. A time-consuming method, based on the analytical detn. of the total Na, total HCO_2H, the HCO_2Na (by CO_2 decompn.), total EtO (modified Zeisel method) and EtOH of crystn. (Zerevitinov), was worked out to decide whether the product contained I or II (later it was found that light could be shed on this question by other means); the results showed that the product prepd. by either of S.'s 2 methods cannot be anywheres nearly pure I; that prepd. by the 1st method may contain up to about 25% II and that prepd. by the 2nd method none at all, and neither can possibly contain a I with the properties given by S. With none of the many prepns. was an evolution of CO on decompn. with H_2O observed. That the ester still held bound in the reaction product is almost certainly present as II was shown by prepg. II in pure form; when it is heated *in vacuo* at 40° according to S.'s 2nd method for prepg. his supposed I, soon only the formate-HCO_2H remains and the end product is a mixt. of EtOH-free NaOEt + HCO_2Na. When EtOH-free NaOEt in Et_2O suspension is allowed to react at 0° with HCO_2Et, the HCO_2Et does not decomp. into CO, and 1 mol. (not more) is bound; the addn. product, which is almost insol. in Et_2O, is an exceedingly hygroscopic microcryst. powder which decomps. into CO at room temp. Attempts to obtain from it derivs. of $HC(OEt)_3$ with $ClCO_2Et$ or $PhCH_2Br$ failed so that it could not be proved directly that it has the structure II. The method previously used to det. the structure of ester-alcoholate addn. products (cleavage of

equiv. amts. of MeOH and EtOH with H_2O or of NaOMe and EtONa with CO_2 from the mixed Et ester-methylate or Me ester-ethylate) does not have the significance then ascribed to it, for, contrary to expectation, the esters may undergo an exchange of the alkyl (*Umesterung*) in Et_2O under the influence of the insol. alcoholate. The addn. product dissolves when treated in Et_2O suspension with $(CO_2Et)_2$ and HCO_2Et is set free; correspondingly, the $(CO_2Et)_2$ addn. product does not react with HCO_2Et. C. A. R.

3-Methylpentanoic acid. E. B. Vliet, C. S. Marvel and C. M. Hsueh. *Org. Syntheses* **XI**, 76–8(1931).—$EtCHMeCH(CO_2Et)_2$, sapond. with KOH and the acid liberated with H_2SO_4 and refluxed 3 hrs., gives 62–5% of $EtMeCHCH_2CO_2H$, b_{743} 193–6°. Caproic acid was obtained in 75% yield by this method. C. J. West

The amides of α-methylbutenoic acids. P. Bruylants, L. Ernould and M. Dekoker. *Bull. sci. acad. roy. Belg.* [5], **16**, 721–40(1930); (cf. *Me m. acad. roy. Belg.* **9**, 16(1927) and *C. A.* **22**, 2366).—The amides, acids and nitriles of α-methylbutenoic acids were prepd. and certain phys. properties observed. The configuration of the angelic and tiglic nitriles were detd. by comparison with crotonic and isocrotonic nitriles and with 3,4- and 2,6-$Me_2C_6H_3CN$. The butenoic nitriles, amides and acids were prepd. by the dehydration of the cyanohydrins with P_2O_5 or $SOCl_2$, preferably the latter. The methylnitriles were converted into methylchlorobutanonitriles by addn. of HCl Treatment with quinoline gave the isomeric butenonitriles. The following compds. were prepd.: (I) α-methyl-β-chlorobutanonitrile, b_{14} 64–5°; (II) α-ethyl-β-chloropropionitrile, b_{14} 73–4°. I on treatment with quinoline gave 2 isomers of α-methyl crotonitrile, b_{12} 121–2° and 137–8°. The high-boiling isomer (III) has been previously described. The low-boiling isomer (IV) gave d_4^{20} 0.81968, n_α^{20} 1.42004, n_D^{20} 1.42303, n_β^{20} 1.43087, $E\Sigma_\alpha$ 0.66. The $ClCH_2CHEtCN$ on treatment with quinoline gave α-ethylacrylonitrile (V), b_{752} 115.0–115.4, d_4^{20} 0.81389, n_α^{20} 1.41440, n_D^{20} 1.41752, n_β^{20} 1.42456, $E\Sigma_\alpha$ 0.51. The amide obtained from III m. 75–6°, that from IV m. 127–8°, and that from V m. 87.7–7.8°. The first 2 amides both yield tiglic acid on hydrolysis or treatment with HNO_2. Also in *Bull. soc. chim. Belg.* **39**, 379–94(1930). Wallace R. Brode

The preparation of ellagic acid. Fritz Zetzsche and Marguerite Graef. *Helv. Chim. Acta* **14**, 240 2(1931).—Ellagic acid (I) was obtained in 4% yield by acidifying the hydrolysis product of Turkish tannin with an equal wt. of Na_2SO_3 crystals. It forms an *addn. compd.* with 2 mols. of pyridine. Acetylation of I or its pyridine compd. with Ac_2O yields *tetraacetylellagic acid*, m. 317–9°. The hydrolytic products also contained 3.3% of 1,2,3-$C_6H_3(OH)_3$. The residue from the aq. ext. of the tannin contained 24% of cellulose. Other tannins also yield I. I. M. Levine

α-Bromoisovaleric acid. C. S. Marvel and V. du Vigneaud. *Org. Syntheses* XI, 20–2(1931).—$Me_2CHCH(CO_2Et)_2$ is sapond., the free acid liberated by HCl, brominated and then heated at 125 30° until evolution of CO_2 ceases; the yield of $Me_2CHCHBrCO_2H$ is 55–66%. C. J. West

Action of ethylmagnesium halides on ethyl diethylcyanoacetate. A. Mavrodin. *Compt. rend.* **192**, 363–5(1931).—EtMgBr or EtMgI reacts with $NCCEt_2CO_2Et$ (I) either at the CN or CO_2Et group but not with both groups in the same mol. The mixt. of products contains Et_2CO, $Et_2CHCOCEt_2CO_2Et$ and Et_2CHCO_2Et; these compds. were also found when PhMgBr was used. Besides these compds. *3-cyano-4-hydroxy-3,4-diethylhexane* (I), b_{20} 132–3°, Et_2CHCN and Et_3COH were also produced. The last was isolated as the *allophanate* (reaction product with HCNO), m. 182–3°. I was transformed into *Δ²-3,4-diethyl-4-cyanohexene*, b_{16} 105°, by reaction with $SOCl_2$. The work confirms the hypothesis that the ester group in I undergoes enolization under the influence of the Grignard reagent; furthermore, the great complexity of the reaction is considered by M. to be due to the inertia and fragility imparted to the mol. by the tetrasubstituted C atom. I. M. Levine

Action of ethylmagnesium bromide on *N*-diethylchloroacetamide. Sou Phou Ti. *Compt. rend.* **191**, 943–5(1930).—The principal product of the action of 3 mols. of EtMgBr on 1 mol. of $CH_2ClCONEt_2$ was neither a chloroamine nor a chloroketone as might have been expected but *2-diethylamino-2-ethyl-1-butanol*, $Et_2C(NEt_2)CH_2OH$ (I) (20% yield), b_{18} 90°; picrate, m. 99°; chloroplatinate, m. 140–1°. Heating I for 3 hrs on a steam bath with excess Ac_2O gave its acetate, b_{13} 97–8°; picrate, m. 130–1°. Other products of the reaction were considerable Et_2NH; about 1% of an ethylenic base, $C_{10}H_{21}N$, with a picrate, m. 74° and a chloroplatinate m. 142–3°; $Et_2NCH_2CONEt_2$, b_{20} 125–6°, with a picrate, m. 121° (Hahn and Loos report 133°, *C. A.* **13**, 725) and a chloroplatinate, m. 164–5°; and the major product was a sirupy, yellowish, basic oil, $C_{14}H_{34}N_2O_2$, b_{14} 160–2°, which did not react with Ac_2O, was not sapond. by 48% HBr, gave no cryst. derivs. and could not be identified. C. H. Peet

Chemistry of thiocholine halides (trimethylthioethylammonium halides). II. Thiocholine chloride and its derivatives. TAICHI HARADA. *Bull. Chem. Soc. Japan* **6**, 25–8(1931); cf. *C. A.* **24**, 2428.—Forty g. of $(CH_2Cl)_2$ was condensed with NMe_3, the chlorocholine chloride (I), $Me_3NClCH_2CH_2Cl$, formed being washed with Et_2O and dried over $CaCl_2$. The 40 g. of crude product, recrystd. from 95% alc. melted about 242°, with decompn. above 163°. Six g. of I was heated with 5 g. of 2-thiouracil together with 25 cc. of H_2O in a bomb tube at 150° for 2 hrs. After filtration from the uracil, the filtrate was neutralized with NH_4OH and on concn. more uracil was removed. Fractional crystn. from a cold mixt. of BzOH and EtOH gave 0.5 g. thiocholine chloride (II), $Me_3NClCH_2CH_2SH$, m. 238° with decompn. above 200°. II reacts with AgCl to form $Me_3NClCH_2CH_2SAg.AgCl$, sol. in H_2O to the extent of 1.215 g. per l. at 37°. It decomps. above 70°, m. 228°. C. R. ADDINALL

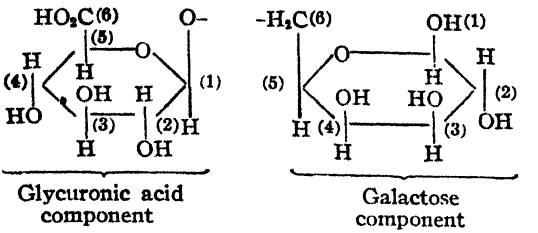
α-Aminoisobutyric acid. H. T. CLARKE AND H. J. BEAN. *Org. Syntheses* **XI**, 4–6 (1931).—Details are given for the prepn. of $Me_2C(NH_2)CO_2H$ from Me_2CO, NaCN and NH_4Cl, giving $Me_2C(OH)CN$; with NH_3 this yields $Me_2C(NH_2)CN$, hydrolyzed by HBr to the acid HBr salt, from which the free acid is obtained in 30–3% yield by C_5H_5N. C. J. WEST

The action of formaldehyde on amino acids with special reference to the formation of amines. LAWRENCE ZELENY AND ROSS A. GORTNER. *J. Biol. Chem.* **90**, 427–41 (1931).—On boiling casein, alanine, cystine, glutamic acid or tyrosine with HCHO in 20% HCl, 12–40% of the total N is converted first into primary, then into secondary and tertiary, amines, which were estd. by Weber and Wilson's method (*C. A.* **12**, 1977). NH_4Cl behaves similarly. The end product, which was reached more rapidly by autoclaving with HCHO at 180° in 5% HOAc, was in all cases NMe_3, identified by the compd. with Reinecke's salt or by the chloroplatinate. The action of HCHO is therefore one of deamination followed by methylation as suggested by Werner (*C. A.* **11**, 3243), but occurring through some intermediate non-volatile, non-amino compd. This compd., which may be a CH_2 deriv., was not isolated, but after the amino-acid N has reached a const. value, the amt. of volatile N continues to increase on boiling. K. V. THIMANN

***N*-Alkylation of β-amino esters.** J. DÉCOMBE. *Compt. rend.* **191**, 945–7(1930).—Alkylation of β-amino esters by treatment with alkyl iodides proceeds unsatisfactorily because it is impossible to fractionate the resulting mixt. by distn. and because there is decompn. of the parent amine through splitting out of NH_3 with resultant formation of an unsatd. ester. However, 70% yields of alkylamino esters may be obtained by the catalytic hydrogenation in EtOH of equimol. mixts. of the β-amino ester and the appropriate aldehyde, with PtO_2 (Adams) as a catalyst. The reaction doubtless proceeds through a condensation of the amine with the aldehyde and reduction is accompanied by the formation of a certain amt. of resin. The following compds. were prepd. by condensing the proper β-amino ester with AcH: $MeCH(NHEt)CH_2CO_2Et$ (I), b_{12} 74–5° (HCl salt, m. 125°); $MeCH(NHEt)CH_2CO_2H$, m. 169 70°; $PrCH(NHEt)CH_2CO_2Et$, b_{20} 110–1° (HCl salt, m. 79°); $C_5H_{11}CH(NHEt)CH_2CO_2Et$, b_{20} 130–2° (HCl salt, hygroscopic, m. about 60°); $C_5H_{11}CH(NHEt)CH_2CO_2H$, m. 140–1°. The method is not so satisfactory for the introduction of 2 alkyl groups. With aldehydes of low mol. wt., a mixt. of amino esters is obtained which cannot be fractionated. Aldehydes of higher mol. wt. yield a small quantity of the dialkyl deriv. $MeCH(NEtBu)CH_2CO_2Et$, from PrCHO and I, b_{15} 118–9° and forms a viscous HCl salt but a microcryst. chloroplatinate. Prepn. of dialkyl derivs. by treatment of the monoalkyl compds. with RI is also unsatisfactory. (The b. p. at 17 mm. of $MeCH(NH_2)CH_2CO_2Et$, incorrectly given in *C. A.* **24**, 2110, is 68–9°.) C. H. PEET

***N*-Acyl derivatives of alanine. Resolution of externally compensated *m*-nitrobenzoylalanine.** WM. M. COLLES AND CHARLES S. GIBSON. *J. Chem. Soc.* **1931**, 279–85.—The *N*-acyl derivs. of alanine (I) were studied not only as a means of isolating and identifying it but also because the nitroacyl derivs. may serve as convenient starting materials for prepg. arsonic acids for the study of the relative chemotherapeutic activities of *dl*- and active isomers. *dl-m-Nitrobenzoyl deriv.* (II) of I, m. 163–4°; at 20° 0.38 g. dissolve in 100 cc. H_2O, 0.37 g. in 100 cc. Et_2O and 0.43 g. in 100 cc. $CHCl_3$; *Ag salt*, needles; *Et ester*, m. 89°; *Me ester*, m. 110–1°; NH_4OH gives the *amide*, m. 189–90°. Reduction of II gives the *NH_2 deriv.*, whose *HCl salt* m. 150–2° (decompn.). *dl-o-Nitrobenzoyl deriv.* (III) of I, m. 165–6°, slightly less sol. in H_2O and Et_2O than II; *o-NH_2 deriv.*, does not m. 270°. *dl-p-Toluyl deriv.* (IV), m. 188–9° (95% yield). *dl-m-Nitrobenzenesulfonylalanine* (V), from I in *N* KOH and *m*-$O_2NC_6H_4SO_2Cl$ in C_6H_6 added at regular intervals, yellow, m. 158.5–9° (89% yield). *dl-4-Nitrotoluene-2-sulfonylalanine* (VI), crystg. with 1 mol. H_2O, m. 91–7°; anhyd., it m. 125.5–6.5°. *dl-Cin-*

namoylalanine (VII), m. 196–7° (30% yield); in alk. soln. it rapidly decolorizes $KMnO_4$, giving BzH. I (15 g.) in 32.4 cc. 0.976 *N* NaOH and 1000 cc. H_2O, treated with 11.92 g. quinine and then with 10 cc. EtOH, gives 17 g. of the *quinine salt* of *l*-I, converted to a glass-like mass at 125°, crystals with 2 mols. H_2O, $[\alpha]_{5461}$ —137.1°; the mother liquor was freed of alkaloid and then treated with brucine, giving 58.2 g. of the *brucine salt* of *d*-I, crystg. with 3.5 mols. H_2O, $[\alpha]_{5461}$ —9.1° (EtOH, *c* 0.5511). *l*-I, m. 158° $[\alpha]^{20}_{5461}$ —44.7° (NH_4 salt in H_2O, *c* 1.342), 5.87° (EtOH, *c* 1.361); *Et ester*, m. 104–5 $[\alpha]^{20}_{5461}$ 6.91° (EtOH, *c* 1.465); in EtOH-KOH (0.0882 g. KOH in 50 cc. EtOH) α_{5461} changes from 0.17 to —1.05° in 26 hrs. *d*-I, m. 158° $[\alpha]^{20}_{5461}$ 44.7° (NH_4 salt in H_2O, *c* 1.358), —5.62° (EtOH *c* 1.335); *Me ester*, m. 126°, $[\alpha]^{20}_{5461}$ —12.7° (EtOH, *c* 1.429); *amide*, m. 193–4°, $[\alpha]^{20}_{5461}$, 24.2° (EtOH, *c* 0.238). The relative rates of hydrolysis of the *dl*-*N*-acyl derivs. were detd. by gently heating 3 hrs. with const.-boiling HCl, neutralizing the hydrolysis mixt. to p_H 8 and titrating the liberated I by Sørensen's method to p_H 10. The % hydrolysis is given: Bz, 96; IV, 95; VII, 92; phthalyl, 76; III, 47, II, 91; *p*-$O_2NC_6H_4CO$ deriv., 97; $PhSO_2$ deriv., 14; α-$C_{10}H_7SO_2$ deriv., 66; β-isomer, 18 (45% after 9.5 hrs.); *p*-$MeC_6H_4SO_2$ deriv., 17; V, 21; VI, 2 in 4 hrs. C. J. WEST



dl-**Glyceraldehyde.** E. J. WITZEMANN, WM. LLOYD EVANS, HENRY HASS AND E. F. SCHROEDER. *Org. Syntheses* XI, 50–1(1931).—Hydrolysis of 50 g. $HOCH_2CH(OH)CH(OEt)_2$ with 500 cc. 0.1 *N* H_2SO_4 at 20° for about 1 week gives 80% of $HOCH_2CH(OH)CHO$, m. 137–9°. C. J. WEST

dl-**Glyceraldehyde acetal.** E. J. WITZEMANN, WM. LLOYD EVANS, HENRY HASS AND E. F. SCHROEDER. *Org. Syntheses* XI, 52–3(1931).—$CH_2:CHCH(OEt)_2$ and $KMnO_4$ in H_2O at 5° give 67% of $HOCH_2CH(OH)CH(OEt)_2$, b_8 120–1°. C. J. W.

The two forms, *cis* and *trans*, of isobutylideneacetone and the isomeric unsaturated β,γ-ketone. R. HEILMANN. *Bull. soc. chim.* [4], 49, 75–80(1931).—Eccott and Linstead have shown (*C. A.* 24, 3991) that the condensation of Me_2CHCHO with Me_2CO gives the *trans*-modification of $Me_2CHCH:CHCOMe$ (I) which on boiling with 20% H_2SO_4 is isomerized into $Me_2C:CHCH_2COMe$ (II). In prepg. $Me_2CHCH(NH_2)N:CMeCH_2$ (III) by the action of $(NH_2)_2.H_2O$ on I, H. obtained a fraction which on hydrolysis with 20% H_2SO_4 gave II. Although II might result from the hydrolysis of the azine produced by the spontaneous oxidation of III (*C. A.* 24, 851), thus regenerating the 2 stereoisomeric forms of I, and by the consequent isomerization of the *trans*-modification, there does not seem to be abs. identity between the residues from the prepn. of III and the products obtained by controlled oxidation of the pyrazoline. In the 1st case the oil obtained consists almost entirely of III whereas in the 2nd case the principal product is I. H. is still of the opinion that I and II are formed simultaneously in the condensation of Me_2CHCHO with Me_2CO and proposes to return to this matter at a later date. C. R. ADDINALL

Compound uronic acids. Structure of the aldobionic acid from gum arabic. SYDNEY WM. CHALLINOR, WALTER N. HAWORTH AND EDMUND L. HIRST. *J. Chem. Soc.* 1931, 258–65.—Aldobionic acid from gum arabic, with $[\alpha]^{20}_D$ 2.0° (Ca salt), on methylation with Me_2SO_4 and 30% NaOH and finally with Ag_2O and MeI, gives a mixt. of α and β-forms of *Me heptamethylaldobionate* (*Me ester of hexamethyl-6-glycuronosido-β methylgalactoside*), $b_{0.02}$ 185°, n^{20}_D 1.4715, $[\alpha]^{20}_D$ —3.5° (H_2O, *c* 1.55), —24° ($CHCl_3$, *c* 2.0), which is non-reducing; after 14 days at 50–60° about 20% of the mixt. seps. as the cryst. β-deriv., m. 86°, $[\alpha]^{20}_D$ —21° (H_2O, *c* 0.67), —43° ($CHCl_3$, *c* 0.65). Hydrolysis of the liquid ester was effected by heating 3.5 hrs. at 100° in 7% HCl, $[\alpha]^{20}_D$ changing from —1° to 63.5° in that time. The 2 hydrolysis products were isolated in 87–8% yields. *2,3,4-Trimethylgalactose*, pale yellow sirup, n^{18}_D 1.4727, $[\alpha]^{20}_D$ 83° (H_2O, *c* 0.6); further methylation gives 2,3,4,6-tetramethyl-β-methylgalactoside. Br-H_2O at 35° for 24 hrs gives *2,3,4-trimethyl-δ-galactonolactone* (after heating 2 hrs. at 100° and 12 mm.), which was characterized as the *phenylhydrazide*, m. 165–7°; the rate of hydrolysis of the lactone is given, becoming const. in 8 hrs. Oxidation of the lactone gives *2,3,4-trimethyl mucic acid*, whose *di-Me ester* m. 98°, $[\alpha]^{20}_D$ 35° (H_2O, *c* 0.6). The other hydrolytic product is *2,3,4-trimethylglycuronic acid*, pale yellow, viscid sirup, n^{16}_D 1.4709, $[\alpha]^{18}_D$ 58° (equil. value in H_2O, *c* 0.63) (this value is for a product that has not been distd.); further methylation gives a mixt. of the α- and β-forms of *2,3,4-trimethylmethylglycuronide*, the β-form m. 133°, $[\alpha]^{23}_D$ —38° (H_2O, *c* 0.4), $[\alpha]^{21}_D$ —63° ($CHCl_3$, *c* 0.6). This was also obtained from glycuronic acid with Me_2SO_4 and alkali. In *N* HCl at 100° the velocity of hydrolysis of the glycuronide was almost identical with that of β-Me glucoside under

similar conditions. Thus, the structure of the aldobionic acid from gum arabic appears to be:

It is not certain whether α- or β-glycuronic acid is involved in the biose linking, although preliminary evidence favors the β-linking. C. J. WEST

Ethyl ethylenetetracarboxylate. B. B. CORSON AND W. L. BENSON. *Org. Syntheses* **XI**, 36–8(1931).—$BrCH(CO_2Et)_2$ (1.25 mols.) and 1.9 mols. anhyd. Na_2CO_3, heated 3 hrs. at 150–60°, give 75–80% of $[:C(CO_2Et)_2]_2$, b_8 197°, b_{13} 203°, b_{22} 210°, b_{33} 221°, b_{48} 234°, m. 52.5–3.5°. The soly. in 95% EtOH is reported for 0 to 36.5°. C. J. WEST

Condensations giving diethyl dicyanoglutaconate. YOSHIYUKI URUSHIBARA. *Bull. Chem. Soc. Japan* **6**, 29–31(1931).—The compd. termed di-Et dicyanoglutaconate, $C_{11}H_{12}O_4N_2$ (I) (*C. A.* **21**, 3889), is now considered to be the semihydrate $(C_{11}H_{12}O_4N_2)_2.H_2O$ (II). The acidification of di-Et sodiodicyanoglutaconate gives II and so attempts were made to form I by direct condensation rather than by proceeding through this intermediate Na compd. Two such condensation processes were carried out in which the formation of I was proved by the pptn. of II on acidifying the alkali ext. of the crude products, *e. g.*, the condensation of $HOCH:C(CN)CO_2Et$ with $CNCH_2CO_2Et$ by the action of Ac_2O and the condensation of $ClCH:C(CN)CO_2Et$ with $ClCH(CN)CO_2Et$ by the use of metallic Cu. C. R. ADDINALL

Mesaconic acid. R. L. SHRINER, S. G. FORD AND L. J. ROLL. *Org. Syntheses* **XI**, 74–5(1931).—Citraconic anhydride (100 g.), 100 cc. H_2O and 150 cc. dil. HNO_3, evapd. to red fumes, give 43–52% of mesaconic acid, m. 203–5°. C. J. WEST

Ethyl pimelate. ADOLF MÜLLER AND ERICH RÖLZ. *Org. Syntheses* **XI**, 42–5 (1931).—Details are given of the reduction of o-$HOC_6H_4CO_2H$ with iso-AmOH and Na and the esterification of the acid; yield of ester, b_{24} 153–6°, 35–8%. C. J. WEST

Citraconic anhydride and citraconic acid. R. L. SHRINER, S. G. FORD AND L. J. ROLL. *Org. Syntheses* **XI**, 28–9(1931).—Itaconic anhydride, distd. rapidly at atm. pressure, gives 68–72% of citraconic anhydride; soln. in slightly more than the necessary amt of H_2O gives 94% of the acid. C. J. WEST

Fumaric acid. NICHOLAS A. MILAS. *Org. Syntheses* **XI**, 46–8(1931).—Oxidation of furfural with $NaClO_3$ (V_2O_5 as catalyst) gives 50–8% of fumaric acid. C. J. WEST

Cyanogen bromide. W. W. HARTMAN AND E. E. DREGER. *Org. Syntheses* **XI**, 30–1(1931).—Details are given of the reaction of NaCN and Br, giving 73–85% of BrCN. C. J. WEST

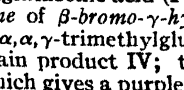
Isopropyl thiocyanate. R. L. SHRINER. *Org. Syntheses* **XI**, 92–3(1931).—Directions are given for the prepn. of Me_2CHSCN from iso-PrBr and NaSCN in 76–9% yields. C. J. WEST

Oxidation. IV. Action of ferric chloride and hydrogen peroxide on *S*-alkylthiosemicarbazones. Formation of triazoles. SATISH CHANDRA DE AND TARANI KANTA CHAKRAVORTY. *J. Indian Chem. Soc.* **7**, 875–8(1930); cf. *C. A.* **24**, 4781.—By oxidation of *S*-alkylthiosemicarbazones of aldehydes thiodiazole formation is excluded and triazoles formed. Yields with $FeCl_3$ were poor but with H_2O_2 the reaction proceeds smoothly. *5-Phenyl-3-methylthiol-1,2,4-triazole*, m. 164°, was obtained by condensing $NH_2C(SMe):NNH_2$ and BzH in alc. followed by H_2O_2 oxidation without isolation of the intermediate compd. *5-Phenyl-3-ethylthiol-1,2,4-triazole*, m. 166°. *Benzylidene-S-methyl-4-phenylthiosemicarbazone*, m. 66–7°; *HI salt*, m. 153°. *4,5-Diphenyl-3-methylthiol 1,2,4-triazole*, m. 165–6°. *Benzylidene-S-ethyl-4-phenylthiosemicarbazone*, m. 78°; *HI salt*, m. 118°; *HCl salt*, m. 178° (decompn.). *4,5-Diphenyl-3-ethylthiol-1,2,4-triazole*, m. 148°. *Benzylidene-S-methyl-4-o-tolylthiosemicarbazone*, m. 62°; *HI salt*, m. 189° (decompn.); *HCl salt*, m. 194° (decompn.). *4-o-Tolyl-5-phenyl-3-methylthiol-1,2,4-triazole*, m. 130°. *Benzylidene-S-ethyl-4-o-tolylthiosemicarbazone; HI salt*, m. 123°; *HCl salt*, m. 167°. *4-o-Tolyl-5-phenyl-3-ethylthiol-1,2,4-triazole*, m. 107°. *Benzylidene-S-methyl-4-p-tolylthiosemicarbazone*, m. 71°; *HI salt*, m. 180° (decompn.); *HCl salt*,

m. 130° (decompn.). *4-p-Tolyl-5-phenyl-3-methylthiol-1,2,4-triazole*, m. 176°. *Benzylidene-S-ethyl-4-p-tolylthiosemicarbazone; HI salt*, m. 165°; *HCl salt*, m. 158°. *4-p-Tolyl-5-phenyl-3-ethylthiol-1,2,4-triazole*, m. 148°. FOSTER DEE SNELL

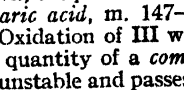
Carbamidosulfonic acids. PAUL BAUMGARTEN AND ILSE MARGGRAFF. *Ber.* **64B**, 301–9(1931).—*N*-Pyridiniumsulfonic acid and urea give $NH_2CONHSO_3(C_5H_5N,H)$ (I) or $CO(NHSO_3)_2(C_5H_5N,H)_2$ (II) depending on the mol. proportions. The free acids are unstable. Both form stable metal salts. The salts of I in acid soln. decomp. into urea and H_2SO_4; in neutral or acid soln. (*i. e.*, the mono- or disalts) decomp. into NH_3, CO_2 and H_2NSO_3Na. The salts of II in acid or neutral soln. decomp. into urea and H_2SO_4 and also into CO_2 and NH_2SO_3H. The neutral disalts decomp. in dil. soln. into CO_2 and H_2NSO_3Na and in solns. over 2% into urea and $NaHSO_4$. The tetrasalts are very stable. These reactions are analogous to those of nitrourea. V. F. HARRINGTON

Preparation of xanthates and other organic thiocarbonates. LAURENCE S. FOSTER. Dept. Mining and Met. Research, Univ. of Utah, *Tech. Paper* **2**, 8 pp.(1928).—The history of the xanthates is reviewed and methods are described for the prepn. of iso-Am, hexyl, heptyl, octyl, nonyl, lauryl and other xanthates, and K alkyl monothiocarbonate, Na Bu and K iso-Am trithiocarbonates. ALDEN H. EMERY



A catalyst for the autoxidation of uric acid. M. FRÈREJACQUE. *Compt. rend.* **191**, 949–51(1930).—Autoxidation of uric acid (I) in KOH can be reduced from 15 hrs. to 10 min. by the addn. of 5% of active C, thus eliminating side reactions. Active C also catalyzes the alk. oxidation of 1-methyl-, 1,3-dimethyl-, hydroxymethylene- and 7-methyl- (II) uric acids although total oxidation of II in the absence of the catalyst appears impracticable. Autoxidation of allantoin (III) by active C in alk. soln. is slow and gives 30% of K oxonate (IV). In the absence of the catalyst, this step cannot be observed on account of the preponderant hydrolysis of III to allantoic acid. There is no autoxidation of the other purines (xanthine (V), hypoxanthine, caffeine, theobromine, etc.) even in the presence of C; hence, pure V is easily obtained by agitating the crude product from the reduction of I with O and C. Autoxidation of I fixes between 1 and 2 atoms of O per mol. of I—most at low temps., least at high. Acidification after oxidation at ordinary temps. gives a mixt. of III and IV, the amt. of IV increasing as the amt. of O absorbed increases. When I is oxidized at 0° in the presence of 1% of C, there is no evolution of NH_3 and acidification after filtering out the C ppts. oxonamide (VI). Perhaps the oxidation proceeds as follows: a peroxide of I (RO_2) is formed; this can decomp. into RO and O (C catalyzes this decompn.), the reagents present decomp. the RO_2 and RO into III and VI. C. H. PETER

Acetone compounds of the sugars and their derivatives. XVII. Conversion of monoacetoneglucose into a new amino- and anhydroglucose. Also a contribution to acyl migration. HEINZ OHLE AND RUDOLF LICHTENSTEIN. *Ber.* **63B**, 2905–12(1930); cf. *C. A.* **24**, 1351.—In connection with the tautomerism problem of the sugars it was of interest to prep. the still unknown glucosyl-5-amine. 5-*p*-Toluenesulfonyl-6-benzoylacetoneglucofuranose seemed to be a suitable starting material for this purpose, and after all attempts partially to hydrolyze it to the toluenesulfonylacetoneglucofuranose (I) had failed (the $MeC_6H_4SO_2$ group was split off along with the Bz group), it was treated directly with NH_3 in MeOH. The reaction might conceivably proceed in various directions. Presumably, the Bz group is first split off and the intermediate I might then (1) yield acetoneglucosyl-5-amine (II) by simple exchange of the $MeC_6H_4SO_2$ group for NH_2, or (2) lose $MeC_6H_4SO_3H$ to form 5,6-anhydroacetoneglucose (III) and add NH_3 to give acetoneglucosyl-6-amine (IV). Moreover, a Walden inversion at the 5-C atom might occur in either (1) or (2), giving (3) acetoneidosyl-5-amine (V) or (4) acetoneidosyl-6-amine (VI) through the corresponding ethylene oxide. As a matter of fact, the reaction is more complicated and has not yet been entirely cleared up but the results thus far obtained are published now because of the appearance of Josephson's paper (*C. A.* **24**, 5285) in which he announces that he is going to attempt to prep. acetoneglucose-5-phosphoric acid. The reaction with NH_3 in MeOH proceeds only slowly at room temp. and the rotation of the mixt. does not become const. even after 3 weeks. If the reaction is interrupted after 14 days, there can be isolated the *p-toluenesulfonate* (VII) of an acetonehexosamine (VIII) and a sirupy, N-free, neutral substance (IX). VII is different from the toluenesulfonate of V. HNO_2 gives an acetoneanhydrohexose (X) different from either III or the 3,6-compd., nor, from its mol. wt. and low m. p., can it be a dimer of either of these compds. It does not add NH_3 even at 100°. Nor is the ring opened by acids, not even by *N* H_2SO_4 at 100°; there is merely obtained the free anhydrosugar (XI) which, like 3,6-anhydroglucose, is sweet and shows no mutarotation. This stability toward hot dil. mineral acids makes it very improbable that the O bridge is between C atoms 3 and 5. It is therefore assumed that XI is *3,6-anhydroidose* and



VIII is *acetoneidosyl-6-amine*. Of the 4 possible reactions mentioned above, apparently only (4) takes place. Some other reaction also takes place at the same time, however, as indicated by the formation of IX which on acetylation gives an *acetyldi-p-toluenesulfonylacetonehexose* (XII) different from the 3,5,6-compd. and characterized by a surprising resistance to dil. mineral acids. Whatever the structure and configuration of IX may be, its formation is an entirely new phenomenon in the chemistry of the sugars; since the starting material contained only one $MeC_6H_4SO_2$ group, one part of it must have been toluenesulfonated, under the influence of the NH_3-MeOH, at the expense of another part; the 5-position of the $MeC_6H_4SO_2$ group is thought to stand in some causal relationship with this reaction. VII (15 g. from 44 g. of the toluenesulfonylbenzoylacetoneglucose), m. 173–4° (decompn.), $[\alpha]_D^{20}$ —23.49° (H_2O, *c* 3.150) (the salt of V decomps. 176–7°, $[\alpha]_D^{20}$ —7.02° (H_2O, *c* 5.01)). XII, m. 112°, does not reduce Fehling soln. until after treatment with concd. H_2SO_4 or heating with NH_3-MeOH at 100°, $[\alpha]_D^{20}$ 2.87° ($CHCl_3$, *c* 2.436) (the 3,5,6-compd. m. 92°, $[\alpha]_D^{19}$ —28.76° ($CHCl_3$, *c* 4.347)). H_2SO_4 (0.05 *N*) completely splits off the Me_2CO from VIII only after 8 days at 37°, $[\alpha]_D$ in a 1-dcm. tube (*c* 10) falling from —1.0° to —0.25°. Direct treatment of the hydrolyzate (after distg. off the Me_2CO split off and neutralizing the H_2SO_4 with KOAc) gives with $PhNHNH_2$ *phenylhydrazine p-toluenesulfonate*, $C_{13}H_{16}O_5SN_2.H_2O$, m. 183–4° (decompn.), identical with Ohle and v. Vargha's supposed toluenesulfonate of the phenylhydrazone of glucosyl-6-amine. *p-Nitrophenylosazone* of XI, dark red-brown, m around 227°. *Tri-Bz deriv.* of VIII, m. 192°, $[\alpha]_D^{20}$ —19.30° ($CHCl_3$, *c* 2.280); one of the Bz groups is held very loosely and the compd. is partially alcoholyzed when crystd. from alc. *Tri-Ac deriv.* of IV, m. 86°, $[\alpha]_D^{18}$ 18.35° ($CHCl_3$, *c* 2.452); *tri-Bz deriv.*, m. 198–9°, $[\alpha]_D^{20}$ —76.43° ($CHCl_3$, *c* 2.682), is not appreciably alcoholyzed; *di-p-toluenesulfonyl deriv.*, m. 172° (decompn.), $[\alpha]_D^{19}$ —2.54° ($CHCl_3$, *c* 3.145). *Hexabenzoylglucosyl-6-amine*, needles with 1 mol. PhMe, reduces Fehling soln., $[\alpha]_D^{20}$ 22.89° ($CHCl_3$, *c* 0.830). *Acetone-3,6-anhydroidose* (X) (yield, 80%), m. 105°, $b_{0.8}$ 147–8° (bath temp.), $[\alpha]_D^{20}$ 24.94° (H_2O, *c* 2.566), mol. wt. in H_2O 202.1 (*c* 1.022) (3,6-anhydroacetoneglucose, m. 56–7°, $[\alpha]_D^{20}$ 29.33° (H_2O)); III, m. 133.5°, $[\alpha]_D^{20}$ —26.5° (H_2O). XI, m. 105–6°, is markedly hygroscopic, strongly reduces hot Fehling soln., $[\alpha]_D^{20}$ 25.36° (H_2O, *c* 3.510) (3,6-anhydroglucose, m. 118°, $[\alpha]_D^{20}$ 55.39° (H_2O, *c* 2.888)). C. A. R.

Report (No. 93) of the most important work in the field of pure sugar chemistry published during the first half of the year 1930. E. O. v. LIPPMANN. *Deut. Zuckerind.* 55, 1104, 1131–3, 1178–9, 1204(1930).—A comprehensive review. J. L. LEETE

Essential oil of Backhousia angustifolia. III. Constitutions of angustione and dehydroangustione. ROBERT S. CAHN, CHARLES S. GIBSON, ARTHUR R. PENFOLD AND JOHN L. SIMONSEN. *J. Chem. Soc.* **1931**, 286–94; cf. *C. A.* **24**, 3998.—The constitution ascribed to angustione (I) is further confirmed by the action of HBr, which gives 1,1,3-trimethylcyclohexane-4,6-dione, m. 130–1°, and by its oxidation with KOBr to $HO_2CCHMeCH_2CMe_2CO_2H$, m. 91.2°, $[\alpha]_{5461}$ —12° (H_2O, *c* 1.546); oxidation with $KMnO_4$ gives a ketonic acid, further oxidized to the above acid with KOBr. Dehydroangustione (II), *p*-$MeC_6H_4NH_2$ and $ZnCl_2$, heated 2 hrs. at 140–50°, give the *p-toluidino deriv.*, m. 63.5°. Heating II with HBr on the H_2O bath for 4 hrs. gives 1,1,3-trimethyl-Δ^2-cyclohexene-4,6-dione (III), m. 156–7°. Reduction of II gives *dl*-angustione, b_{14} 127°, d_{20}^{20} 1.083, n_D^{20} 1.5087 (identical with the natural ketone, except for the value of *n*; the previous sample was contaminated with II); the *amino deriv.*, m. 139–40°, is formed by adding NH_4OH to the EtOH soln.; the *4*(or *6*)-*oxime*, m. 57–8°. Oxidation of II with NaOBr gives a mixt. of a compd. m. 88.5°, identified as the anhydride of *cis*-α,β,γ-

(I)

(II)

trimethylglutaconic acid (IV), m. 125° (on bromination, the product evolves HBr, giving the *lactone* of *β-bromo-γ-hydroxy-α,α,γ-trimethylglutaric acid*, m. 147–8°) and *trans*-β-hydroxy-α,α,γ-trimethylglutaric acid, m. 156–7°. Oxidation of III with NaOBr gives as the main product IV; there also results a small quantity of a *compd.*, $C_8H_{12}O_3$, m. 85–6°, which gives a purple color with $FeCl_3$; this is unstable and passes into a red oil on standing; it may be $OC.CHMe.CH_2.CMe_2.CO$ or $HOC:C(OH).CMe:CH.CMe_2$.

Note on the parachors of angustione and dehydroangustione. OWEN J. EVANS AND

FREDERICK G. SOPER. *Ibid* 289–90.—*dl*-I, m. 151–2°, γ_{20} 34.9, *P* 442 (calcd., 462.1); II gave γ_{20} 36.7, *P* 435 (calcd., 439.5); the d^{20} were 1.083 and 1.103, resp. The temp. coeff. of the surface tension for I is —0.072 dyne/cm. per degree, d^{40} 1.074, Ramsay-Shields const. 2.05; this indicates that I is a normal liquid, so that the neg. anomaly cannot be attributed to assocn. The reason for this is discussed. C. J. WEST

Model experiments for the theory of alcoholic fermentation. III. Degradation of α-diacetonefructosesulfuric acid. HEINZ OHLE AND GEORG COUTSICOS. *Ber.* **63B**, 2912–27(1930); cf. *C. A.* **24**, 1350.—It was shown in Paper I that β-diacetonefructose-1-sulfuric acid (I) with aq. neutral $KMnO_4$ gives the tri-K salt of 2,3-acetone-β-*l*-furtondiacid-1-sulfuric acid (II) (the mother substance, $HOCH_2C(OH)_2CH(OH)CH(CO_2H)_2$, being designated as furtondiacid). The prepn. of this salt has since been materially improved and simplified and it is now quite readily available. A weak point in the proof of its constitution was the detection and quant. estn. of the $HOCH_2CO_2H$ formed in its hydrolysis but this gap has now been filled in. On the basis of the fact that $HOCH_2CO_2H$ forms a difficultly sol. basic Pb salt a quant. method for detg. this acid, sufficiently accurate for the present purpose, was devised and it was found that the above tri-K salt does in fact give 1 mol. $HOCH_2CO_2H$, as previously assumed. That the yield of MeCOCHO does not exceed 80% is probably due to a small part of it undergoing a Cannizzaro reaction, with formation of $AcCO_2H$ and $AcCH_2OH$; the latter, though not isolated, was shown to be present by its characteristic odor. The reaction was next applied to α-diacetonefructose-3-sulfuric acid (III). Whereas with I the formation of II and the point where it is present in greatest concn. can be readily recognized by following the oxidation polarimetrically to the max. in the rotation curve, the curve for III shows no such max. With 12 atoms O the III is completely broken down into optically inactive products, as is demanded by theory if the Me_2CO split off is not attacked. If each mol. of III were at once broken down into the final products (Me_2CO, H_2O, CO_2, H_2SO_4) before the next mol. underwent the same change, the rotation curve should be a straight line, but, as was to be expected, it is not. To obtain further light on the course of the reaction, the splitting off of the H_2SO_4 was also followed and here again the curve obtained by plotting the no. of mols. H_2SO_4 split off against the no. of atoms of O used was not a straight line. In both cases the max. deviation from a straight line was at a point corresponding to about 6 atoms O, and at this point it was possible to isolate an almost optically inactive product (IV) having the same compn. as II, *viz.*, the tri-K salt of *1,2-acetone-α-l-furtondiacid-3-sulfuric acid*, and yielding the same hydrolysis products. Attempts to isolate intermediate products in the formation of II and IV in order to det. at what point of the fructose mol. (C atom 5 or 6) oxidation first begins were unsuccessful, and the study of α acetonefructose-3-sulfuric acid (V) was therefore undertaken. Since here the 4- and 5-HO groups are free, the V should be more readily attacked by $KMnO_4$ and the first oxidation phase should use up more $KMnO_4$ than with III and less $KMnO_4$ would be left for the further oxidation so that there would be an increased accumulation of the intermediate oxidation product. The max. deviation of the exptl. rotation curve from a straight line appeared at the point corresponding to 5 atoms O, and at this point there were obtained large quantities of IV but also, although in small quantity, the di-K salt of *1,2-acetonefructuronic-3-sulfuric acid* (VI), showing that, in part, at least, it is the 6-C atom which is first attacked. Whether VI is an intermediate or a by-product in the formation of IV could not be detd. for lack of material. VI, the first deriv. of the hitherto unknown fructuronic acid, the analog in the ketose series of glucuronic acid, is decompd. by boiling dil. HCl into Me_2CO, H_2SO_4 and CO_2, but the latter is evolved much more slowly than from II or IV. MeCOCHO and furfural were not formed. To det. how the OSO_3H residue influences the course of the oxidation of α- (VII) and β-diacetone- (VIII) and α-acetonefructose (IX), the oxidation curves of these compds. were also detd. With VIII the rotation curve also changes from − to +, with a max. at the point corresponding to about 6 atoms O, so that 2,2-acetone-2,2,3-trihydroxyglutar-4-carboxylic acid is probably formed, but the curve does not pass through α_D 0° at the point corresponding to 12 atoms O. The same is true of the curve for VII. The only possible explanation for this is that a part of the Me_2CO split off is also oxidized, probably after it has reacted with another cleavage product of the sugar mol. The curve for VII also shows a dispersion of the exptl. values which is not due to exptl. error, as the individual values can be reproduced with great exactitude. It is, therefore, assumed that a whole series of intermediate products is formed through different reactions, one of which, through the furtondiacid, is extraordinarily favored by the introduction of an OSO_3H residue. The curve for IX is parallel to the theoretical (straight line) curve from the points corresponding to 2 up to 9 atoms O, indicating that most of the IX is oxidized directly to Me_2CO, CO_2 and H_2O without the accumulation in

appreciable amount of any intermediate product. If, however, **IX** is not a pyroid fructose but a fructofuranose, the curve might be interpreted on the assumption that with 2 atoms O there is an almost quant. formation of acetonefructuronic acid, but an expt. on a large scale under these conditions yielded only large quantities of unchanged **IX**. **IX** and its 3-sulfate (V) show most strikingly the selective action of the OSO_3H group which evidently depends on its adjacent position to the masked C:O group, the strongly electronegative OSO_3H residue stabilizing the hydrate form of the C:O group and therefore exerting the same influence as the Cl in $CCl_3CHO.H_2O$. By the stabilization of the hydrate form the union of the Me_2CO is also strengthened and the upper end of the mol. is protected from attack by the oxidizing agent. Other electronegative groups must exert the same influence, and, furthermore, oxidation through derivs. of the furtondiacid type in the glucose series is at most possible only in those glucose derivs. having strongly acid residues on the 2-HO group. It is believed, therefore, that a degradation of glucose in the sense of the Neuberg fermentation scheme is possible only by way of fructose. *K salt* of **III**, from **VII** and $ClSO_3H$ in C_5H_5N, needles with $^1/_2$ mol. H_2O, decomps. about 165°, $[\alpha]_D^{20}$ —124.3° (H_2O, *c* 1.094), is practically insol. in abs. alc., swells in ordinary alc. and dissolves on heating, the satd. cooled soln. contg. about 0.7% of the salt; more concd. solns. solidify to a more or less stiff jelly. The alc. in these jellies can be for the most part squeezed out by gentle pressure. The higher alcs. behave like EtOH but with MeOH the property of gelatinizing is less marked. *Na salt*, needles with $1H_2O$, decomps. about 170°, $[\alpha]_D^{20}$ - 128.3° (H_2O, *c* 2.144). The salts are stable toward boiling dil. alkalies but split off Me_2CO and H_2SO_4 with very dil. acids at room temp. *Tri-K salt* of **IV** (20 g. from 100 g. of the K salt of III with 2 *N* $KMnO_4$ (6 atoms O) on the H_2O bath), prisms with $3H_2O$ from MeOH-Me_2CO-EtOH, $[\alpha]_D^{20}$ —1.78°, needles with 4.5 H_2O from MeOH, $[\alpha]_D^{20}$ —2.72°. *K salt* of **V**, obtained by partial hydrolysis of the K salt of **III** with *N* H_2SO_4 at room temp., decomps. about 150°, $[\alpha]_D^{20}$ —112° (H_2O, *c* 1.847). *Na salt*, decomps. 140°, $[\alpha]_D^{20}$ -- 118.6° (H_2O, *c* 2.426). *Di-K salt* of **VI** (5 g. from 100 g. of the K salt of V with 2 *N* $KMnO_4$ (5 atoms O) at 100°), prisms with 4 mols. H_2O (0.5 mol. is firmly held even at 135°), $[\alpha]_D^{20}$ —45.68° (H_2O, *c* 1.345). **IX**, from 50 g. **VII** allowed to stand 3 hrs. at 37° in 250 cc. of 70% AcOH, m 120.5°, $[\alpha]_D^{20}$ —159.3° (H_2O, *c* 1.639). Tri-K salt of II (164 g. from 756 g. of the K salt of I heated 10 hrs. at 100° with 1264 g. $KMnO_4$ in 20 l. H_2O), $[\alpha]_D^{20}$ 29.35° (H_2O, *c* 3.314),

Lignin, humic acid and humin. W. Fuchs. *Z. angew. Chem.* **44**, 111–8(1931); cf. *C. A.* **25**, 761.—Investigations by F. and co-workers are summarized. E. Schotte

Lignin and related compounds. V. Action of halogens on lignin and wood. Harold Hibbert and Charles A. Sankey. *Can. J. Research* **4**, 110–8(1931); cf. *C. A.* **24**, 5151, 5152.—Spruce meal and a variety of lignin products were treated with Br dissolved in a variety of solvents. The addn. of Br was found to be a function of time, concn., solvent used and the acidity of the reacting medium, and quite unsatisfactory for the detn. of unsatn. **VI. The mechanism of aqueous halogenation.** K. Austin Taylor, O. Maass and Harold Hibbert. *Ibid* 119–33.—The rates of addn. of HClO and HBrO to several unsatd. compds., under the influence of various catalysts, have been studied. The addn. of HClO to allyl alc. and dipropenylglycol is catalyzed by both $\overset{+}{H}$ and $\overset{-}{Cl}$, the catalytic effects of these ions, mole for mole, being equal. The effect of $\overset{+}{H}$ and $\overset{-}{Cl}$, when added together as HCl, is not the sum of their sep. effects but is proportional to their product, indicating undissocd. HCl as the real catalyst. The catalytic effect of varying amts. of added HCl is approx. proportional to the square of the amt. added, again indicating undissocd. HCl as the real catalyst. The addn. of HBrO to allyl alc. is catalyzed by HCl and HBr to about the same degree. This catalysis of HBrO addn. by HCl provides further support for the hypothesis of undissocd. HCl as the real catalyst in the addn. of HClO. This catalytic effect of undissocd. halogen acid on the addn. of hypohalous acids is given as an explanation of the greater rates of addn. of HClO and HBrO from Cl and Br water as compared with solns. of HClO and HBrO. The addn. of HBrO to fumaric acid is not catalyzed by HBr but, on the other hand, is considerably decreased. It is catalyzed, however, by HCl, although not nearly to the same degree as the addn. to allyl alc. This difference in behavior between fumaric acid and allyl alc. shows the necessity for studying the effect of HCl and HBr on the rate of addn. of HBrO to a wide variety of unsatd. compds., before any general theory of aq. halogenation applicable to all types of unsatd. compds. can be put forward. The

possible influence of conjugation has, however, been pointed out. An attempt has been made to apply the theory of hypohalous acid addn. catalyzed by undissocd. halogen acid to the aq. halogenation of phenols. The reaction between HBrO and *m*-nitrophenol has been shown to be catalyzed by HCl although not to the same extent as by HBr. This indicates HBrO addn., catalyzed by undissocd. HBr, as one of the mechanisms involved in the aq. bromination of phenols. A similar mechanism cannot be the fastest one in the aq. chlorination of phenols, since it is in disagreement with kinetic data of Soper and Smith (*C. A.* **20**, 2840), showing Cl to react faster than HClO with phenols. Resorcinol and phloroglucinol do not fall under the general classification proposed by Soper and Smith for phenols. Even here, however, the main reaction between Cl water and the phenol seems to involve Cl rather than HClO. Several parallel mechanisms may be involved in the aq. halogenation of phenols and the necessity for further work in this field has been emphasized. J. W. SHIPLEY

The enolization of ketones. V. GRIGNARD AND H. BLANCHON. *Bull. soc. chim.* [4], **49**, 23–42(1931).—The Grignard reagent has an enolizing reaction on ketones (*C. A.* **21**, 731), and it is possible to esterify the mixt. of enol so produced and the accompanying tertiary alc. from the normal reaction by means of acid chlorides or anhydrides. After sepn. of the esters by distn., the enolic ester can be hydrolyzed with H_2O. With certain precautions the enol-keto mixt. can be isolated by the decompn. of the Mg complex by NH_4Cl (*C. A.* **20**, 751). A systematic study was undertaken to establish a relation between the constitution of the ketone, its aptitude for enolization and the stability of the enol, the present paper dealing with the enolization of ketones (*C. A.* **24**, 1342), and the prepn. of the enols. To obtain the max. amount of enolate iso-PrMgBr was selected as being the most readily prepd. reagent. In general, the ketone was dissolved in an equal vol. of Et_2O and gradually introduced into the reagent. After refluxing for 30 min. and then cooling to —5°, the theoretical amt. of AcCl in 5 vols. of Et_2O was added dropwise with stirring and the resulting yellow mass was dropped into iced water contg. $NaHCO_3$. The washed and dried Et_2O exts., freed from Et_2O, were distd. under reduced pressure, giving 3 fractions, the keto-enol mixt., the enol acetate and the acetate of the tertiary alc. *Cyclohexanone-enol.*—100 g. of cyclohexanone gave 5 g. of keto-enol mixt. contg. 30% enol, 25 g. of the enol ester and 60 g. of isopropylcyclohexanol, b_{12} 125°. The ester was hydrolyzed with 10% $(CO_2H)_2$, yielding a 70% enol, n_D^{12} 1.4601. The tautomerization to cyclohexanone was complete in 10 hrs., the transformation being retarded by $(CO_2H)_2$, but not by $C_6H_4O_2$ or *o*-$C_6H_4(CO_2)O$, and accelerated by mineral acids, alkalies and Br. *Thujone-enol.*—Thujone formed mainly isopropylthujol acetate, b_{12} 125°, on treatment with iso-PrMgBr, and also some thujone-enol mixt. contg. 89.5% enol, n_D^{15} 1.4540, which reverts to the ketone in 15 hrs. The ketonization is completed in 2 hrs. with $NaHCO_3$ and instantaneously with Br, demonstrating the difficulty of obtaining the pure enol and the inapplicability of the Kurt Meyer method. *Carvone-enol.*—200 g. of carvone, enolized by EtMgBr, gave ethylcarveol, b_{12} 142°, and 15 g. of 96.5% carvone-enol, b_{12} 114–5°, d_{15}^4 0.957, n_D^{15} 1.5151, R. M. 47.2, calcd. 46.3. After 25 hrs. the mixt. contains 1.5% enol, tautomerization being accelerated by light, acids and alkalies. With Br the ketonization is complete in 1 hr. at 15° and in 15 mins. at 40°. The Kurt Meyer method applied at 0° would give results 10% below those furnished by the detn. according to Job and Reich. *Enol of mesityl oxide.*—Enolization of 100 g. of $Me_2C{:}CH{-}COMe$ with iso-PrMgBr yielded in addn. to 31 g. of 2,3,5-trimethyl-4-hexen-3-ol, b. 172°, and 10 g. of enol acetate, 21 g. of a 70% enol, b. 134°, d_{12}^4 0.8610, n_D^{12} 1.4500, R. M. 30.8, calcd., 30.18, which ketonized in 5 hrs. to 6.4% enol. Enols can be formed through the chlorohydrins. These are transformed into the acetic ester by AcOK and then treated as above. From pulegone was obtained 50% yield of a 98.2% enol, b_3 79–81°, n_D^{12} 1.48115, d_{12}^4 0.9130, R. M. 47.38, calcd. 46.76. The 75% enol derived from MeBz through the chlorohydrin was a very unstable liquid, b. 205°. Tautomerization was complete in 10 hrs. in the dark, 5 hrs. in light and was instantaneous in the presence of acids and alkalies. The ketonization was accelerated with Br. The enol did not give a color reaction with $FeCl_3$ nor did it form an ammoniacal enolate. C. R. A.

Bromomesitylene. LEE I. SMITH. *Org. Syntheses* **II**, 24–5(1931).—Details are given of the bromination of $C_6H_3Me_3$ in CCl_4 at 10–5°, the yield of $C_6H_2Me_3Br$ being 79–82%; traces of side-chain derivs. are removed by treatment with EtONa. The Br deriv. b_{62} 132°, b_{70} 139°, b_{78} 146°, b_{100} 157°. C. J. WEST

Process for the preparation of mesitylene. V. IPAT'EV, B. DOLGOV AND I. VOLNOV. *Ber.* **63B**, 3072–8(1930).—Ipat'ev, Jr., in connection with his work on the displacement of metals of the 5th group from their chlorides ($SbCl_3$, $BiCl_3$) by H in Me_2CO under pressure, noticed an extensive condensation of the solvent, irrespective of the salt used,

which occurred even when the solns. were dild. with H_2O. This made it seem probable that the condensation to mesitylene (I) and higher condensation products depends not only on the dehydrating action of the HCl but also on a catalytic action exerted by it. The present authors were chiefly interested in the mechanism of the condensation to I, and since the use of H_2SO_4 under the same conditions resulted in a very deep-seated condensation with formation of S-contg. products, they discarded this acid and used HCl. By choosing the mildest possible conditions and studying the effect of varying them they were able to det. the optimum conditions for the prepn. of I. Using the Ipat'ev high-pressure app., they found that the yield of I after 24 hrs. at 175° (initial pressure 100 atm.) rapidly increases with increasing concn. of HCl up to 5 vol. % of d. 1.19 acid and then slowly falls as the HCl concn. is increased to 50 vol. %, where higher, terpene-like condensation products appear. This explains the poor yields of I from Me_2CO satd. with HCl. Keeping the concn. of HCl const. (5 vol. %) and varying the temp. gave a very rapid increase in yield (based on the Me_2CO not recovered) with increasing temp. up to 140°; the yield based on the total amt. of Me_2CO charged into the app. reached its max. at 170°; from 175° to 190° the 2 curves coincided, pointing to a complete utilization of the Me_2CO charge. A very significant fact is the decrease in lower, O-contg. condensation products (mesityl oxide) with increasing temp. Under optimal conditions (5 vol. % and 145°), the yield of I no longer increases after 24 hrs.; up to this point the yield increases very regularly. Under these conditions 3–4.5% mesityl oxide could be isolated as the primary condensation product. The absence of phorone in the condensation products indicates that either it is not formed at all under these conditions or quantitatively undergoes further condensation. Under the above optimal conditions, com. Me_2CO gives 43% I, based on the Me_2CO not recovered; up to 50% of the Me_2CO charged does not react but it can be put through the process again. At 175–80° practically all the Me_2CO is used up, giving 36% I, as against only 17.5% previously obtained. C. A. R.

Isodurene (1,2,3,5-tetramethylbenzene). Lee I. Smith. *Org. Syntheses* **XI**, 66–9 (1931); cf. *C. A.* **24**, 1850.—2,4,6-$Me_3C_6H_2Br$ gives a Grignard reagent which yields 53–61% of 1,2,3,5-$C_6H_2Me_4$ with Me_2SO_4. C. J. West

The forced reaction between tetraphenylethylene and some organomagnesium derivatives. Henry Gilman and Stanton A. Harris. *Bull. soc. chim.* [4], **49**, 10–12 (1931).—The formation of *o*-phenylbenzohydrylaniline by the action of PhMgBr on $Ph_2C{:}NPh$ (*C. A.* **23**, 3909), in which an addn. is made to a benzene ring in a compd. contg. several closely situated Ph groups, suggested the corresponding reaction with $(Ph_2C{:})_2$ (I). Fifteen g. of I (0.045 mol.) in 150 cc of PhMe was heated with 0.174 mol. of PhMgBr at 60° for 20 hrs. and then at 90–100° for 6 hrs., the mixt. being guarded from the atm. Eighty-six % of I was recovered and on addn. of CO_2 to the reaction mixt. before hydrolysis only BzOH was formed. Similarly, after a forced reaction with $PhCH_2MgCl$, 85.5% of I was recovered and carbonation with CO_2 gave $PhCH_2CO_2H$ uniquely. Neither expt. showed any evidence of any reaction of the type expected in spite of the forced conditions and the highly phenylated nature of I. C. R. A.

2,4-Diaminotoluene. S. A. Mahood and P. V. L. Schaffner. *Org. Syntheses* **XI**, 32–5(1931).—Details are given of the reduction of 2,4-$(O_2N)_2C_6H_3Me$ with Fe and HCl, the di-NH_2 deriv. being obtained in 74% yield. C. J. West

***p*-Iodoaniline.** R. Q. Brewster. *Org. Syntheses* **XI**, 62–4(1931).—$PhNH_2$ in $NaHCO_3$, treated with 1 mol. powd. I_2, gives 75–84% of *p*-$IC_6H_4NH_2$, m. 62–3°. C. J. West

The action of ethyl nitrate on phenylhydrazine in the presence of sodium ethylate. Eugen Bamberger and Otto Billeter. *Helv. Chim. Acta* **14**, 219–32(1931).—The method used for the prepn. of $PhN{:}NO_2H$ from $PhNH_2$, $EtONO_2$ and NaOEt (*C. A.* **15**, 1516) was applied to $PhNHNH_2$ with the hope of obtaining $PhN(:NO_2H){:}NH$ but the attempt failed. $NaNO_2$, C_6H_6, $PhNH_2$, PhNHNHAc, PhN_3, $(PhN{:})_2$, HOAc, N_2 and $MeC(N{:}NPh){:}NNHPh$ (I) were isolated from the reaction mass. Mechanisms for the formation of these compds. are suggested and evidence in their support is offered. I was prepd. in 94% yield from $PhNHN{:}CHMe$ (II) and $PhN(:N)Cl$. In the same manner *nitromethalformamol* [illegible]

I. M. Levine

Condensation of ethyl acetoacetate with aromatic amines. I. G. V. Jadhav. *J. Indian Chem. Soc.* **7**, 669–76(1930).—$AcCH_2CO_2Et$ (I) and aromatic amines give $MeC(NHR){:}CHCONHR$ and either $MeCOCH_2CONHR$ (II) or $MeC(NHR){:}CHCO_2Et$ (III); the effect of substituent groups in the aromatic nucleus was studied. Compds. of

type II were isolated in only a few cases and heating the reaction mixt. was shown to convert them to compds. of type III, except in the case of Et *β-p*-nitroanilinocrotonate. The following compds. were prepd. by refluxing equal wts. of I and the proper amine unless otherwise indicated: *acetoacet-m-nitroanilide* (IV), pale yellow, m. 120–1°; *β-m-nitroanilinocroton-m-nitroanilide* (V), yellow, m. 152–3°; *Et β-p-nitroanilinocrotonate*, yellow, m. 122–3°; *β-p-nitroanilinocroton-p-nitroanilide* (VI), orange, m. above 250°; *acetoacet-p-anisidide* (VII), m. 117–8°; *β-p-anisidinocroton-p-anisidide*, m. 235–6°; *Et p-phenetidinocrotonate*, m. 60–1° (from a cold mixt. on standing 48 hrs.); *β-p-phenetidinocroton-p-phenetidide*, m. 230–1°; *β-m-(1,4,5)-xylidinocroton-m-(1,4,5)-xylidide*, m. above 275°, *β-m-(1,3,4)-xylidinocroton-m-(1,3,4)-xylidide*, m. above 275°; *acetoacet-m-chloroanilide*, m. 105–6°; *β-m-chloroanilinocroton m-chloroanilide*, m. 240–1°; *acetoacet-p-chloroanilide* (VIII), m. 132–3°; *Et β-p-chloroanilinocrotonate*, m. 55° (from a cold mixt. on standing 72 hrs.); *β-p-chloroanilinocroton-p-chloroanilide*, m. above 275°; *acetoacet-o-chloroanilide* (IX), m. 107–8°; and *β-o-chloroanilinocroton-o-chloroanilide*, m. 236°. V and VI with HCl give IV and *acetoacet-p-nitroanilide* (X), m. 122–3°, resp. IV, X, VIII, IX and VII with NH_4OH give the following *anilides* of *β-aminocrotonic acid: m-*NO_2, orange-red, m. 129–30°; *p-*NO_2, yellow, m. 189–90°; *p-MeO*, m. 109–10°; *p-Cl*, m. 110°, and *o-Cl*, m. 96–7°. A. F. Shepard

Azoxybenzene. H. E Bigelow and Albert Palmer. *Org. Syntheses* **XI**, 16–8 (1931).—Details are given of the action of As_2O_3 and NaOH upon $PhNO_2$; PhN:N(:O)Ph results in 85% yields; the compd. is easily volatile with steam at 140–50°. C. J. West

Remarks concerning the most recent work of A. Angeli. Eugen Bamberger *Helv. Chim. Acta.* **14**, 242-9(1931).—A mechanism offered by B. for the reaction by which azohydroxyamides, RN(OH)N:NR, are obtained from the interaction between PhNO (I) and $PhNHNH_2$ (II) or their derivs involves an aldol condensation of the reactants followed by a loss of H_2. This mechanism is in contrast to that given by Angeli who supposed that II is first reduced to PhN:NH which then adds I. Several instances of reactions easily explained by means of the aldol condensation are given. Besides the simple compds., *p*-BrC_6H_4NO (III), $PhMeNNH_2$ (IV) and Ph_2NNH_2 (V) undergo the same type of reaction. From IV and I, *phenylazomethylanilidoxide*, PhMeNN:N(:O)Ph (VI), m. 72°, PhMeNN:NPh (VII) and PhNHMe (VIII) were obtained. By reduction of VI with Zn, VII, VIII, $PhNH_2$ and NH_3 were produced. Condensation of V and I yields *phenylazodiphenylamidoxide*, $Ph_2NN:N(:O)Ph$, m. 128.5–9°, Ph_2NH and PhNHOH. From III and IV *p-bromophenylazomethylanilidoxide*, $BrC_6H_4N(:O)$ NNMePh (IX), m. 77–8°, $BrC_6H_4N:N(:O)C_6H_4Br$ (X), and possibly $BrC_6H_4N:NNMePh$ were isolated. Reduction of IX yielded $(BrC_6H_4N)_2$ (XI) and VIII. III and V interact to give *p-bromophenylazodiphenylamidoxide*, $BrC_6H_4N(:O):NNPh_2$ (XII), m. 119–20°, X and BrC_6H_4NHOH. The reduction products of XII consisted of X, (BrC_6H_4NH), XI, Ph_2NH, $BrC_6H_4NH_2$ and Ph_2NNHAc. I. M Levine

***N*-Diethylamino-*N'*-phenylurea.** R. Stollé and W. Brandt. *J. prakt. Chem* **129**, 206(1931).—Hurd and Spence (*C. A.* **21**, 570) state that Et_2NNH_2 and PhNCO give the compd. PhN:C:NNEt$_2$; S. and B. state the compd. analyzes for $C_{11}H_{17}ON_3$ and is thus a semicarbazide deriv. C. J. West

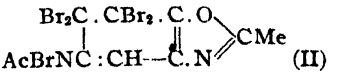
***p*-Methoxybenzylmagnesium bromide.** Henry Gilman and E. A. Zoellner *Bull. soc. chim.* [4], **49**, 7–9(1931).—The extraordinary activity of the halogen in the halides of the type *p*-$MeOC_6H_4CH_2X$ renders these compds. so unstable that various workers have reported that *p*-$MeOC_6H_4CH_2Cl$ does not form a Grignard reagent (*C. A.* **18**, 237; **23**, 823). By a modification of the usual procedure (*C. A.* **23**, 2934) *p*-$MeOC_6H_4CH_2MgBr$ has been prepd. in satisfactory yields. To 1.82 g. (0.075 atom) of Mg, 30–80 mesh, covered with 11.5 cc. Et_2O, were added 10 drops of freshly distd. *p*-$MeOC_6H_4CH_2Br$ (b_{12} 129°, d_{20} 1.41), and then 0.05 g. of I. After boiling for 10 mins. without stirring, 4.35 g. (0.0216 mol.) of the bromide mixed with 23.5 cc. of Et_2O, was added uniformly over a period of 30 mins. with stirring and refluxing. After the addn. this treatment was continued for 10 mins. The resulting soln. gave a positive reaction for organometallic reagent (*C. A.* **19**, 2473) and titrated for 54% *p*-$MeOC_6H_4CH_2MgBr$ (*C. A.* **17**, 530). Treatment with CO_2 gave *p*-$MeOC_6H_4CH_2CO_2H$, m. 84–5°, and some $(p\text{-}MeOC_6H_4CH_2)_2$. The yield could be raised to 75% by using 10–20 atoms of Mg and about 30 mols. of Et_2O per mol. of bromide; an even better yield should be obtained of the corresponding organomagnesium chloride. C. R. Addinall

Sulfur derivatives of 2-methoxytoluene. G. B. Kolhatkar and K. V. Bokil *J. Indian Chem. Soc.* **7**, 843–50(1930).—3,4-$Me(MeO)C_6H_3SO_2Cl$ (I) and 2-$MeOC_6H_4Me$ in CS_2 with $AlCl_3$ give *3,3'-dimethyl-4,4'-dimethoxydiphenyl sulfone* (II), m. 138°. Alk. $KMnO_4$ oxidizes II to *3,3'-dicarboxy-4,4'-dimethoxydiphenyl sulfone* (III), sinters 245°,

m. 250° (decompn.). Distn. of III with CaO-NaOH gives *4,4'-dimethoxydiphenyl sulfone*, m. 129°. With HI, II gives *3,3'-dimethyl-4,4'-dihydroxydiphenyl sulfone*, m. 263°, and III gives *3,3'-dicarboxy-4,4'-dihydroxydiphenyl sulfone*, m. 306–7° (decompn.). Either $PhSO_2Cl$ with 2-$MeOC_6H_4Me$ or I with C_6H_6 give *3-methyl-4-methoxydiphenyl sulfone*, m. 112–2.5°. *3-Methyl-4-hydroxydiphenyl sulfone*, m. 226°. *3-Carboxy-4-methoxydiphenyl sulfone*, m. 176°. *3-Carboxy-4-hydroxydiphenyl* [illegible] *4,4'-dimethoxydiphenyl sulfone*, m. 186–7°. *3'-Methyl-2',4-dimethoxydiphenyl sulfone*, m. 145°. A soln. of $AlCl_3$ in 2-$MeOC_6H_4Me$ satd. with SO_2 gives *3,3'-dimethyl-4,4'-dimethoxydiphenyl sulfoxide* (V), m. 87–87.5°, by ether extn. and 2 isomers of *tri-o-cresylsulfonium chloride*, m. 140–1° and 69–70°, by $CHCl_3$ extn. Reduction of V with AcOH and Zn dust gives *3,3'-dimethyl-4,4'-dimethoxydiphenyl sulfide*, m. 37.5–38°. Reduction of I with Na_2SO_3 and NaOH gives VII (see below) and *2-methoxytoluene-5-sulfinic acid* (VI). The Na salt of VI with I in abs. alc. gives *3,3'-dimethyl-4,4'-dimethoxydiphenyl disulfone* (VII), m. 206.5° (decompn.). *2-Methoxy-5-thioltoluene*, m. 42–3°, b. 236–7°, oxidized in NaOH by I_2-KI gives *3,3'-dimethyl-4,4'-dimethoxydiphenyl disulfide* (VIII), m. 44.5°. Oxidation of VIII in AcOH with H_2O_2 gives *3,3'-dimethyl-4,4'-dimethoxydiphenyl disulfoxide*, m. 118°, identical with that obtained by spontaneous decompn. of VI.

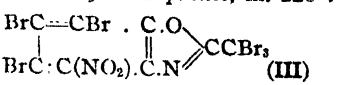
FOSTER DEE SNELL

Relative directive powers of groups of the forms RO and RR'N in aromatic substitution. IX. The nitration of *p*-cetyloxyanisole and *p*-benzyloxyanisole. JOHN C. SMITH. *J. Chem. Soc.* **1931**, 251–8; cf. *C. A.* **22**, 404.—In continuation of earlier work the relative directive powers of the cetyloxy and benzyloxy groups in the quinol series have been measured. The values of the relative directive powers obtained to date are: MeO 100, EtO 164, PrO 180, BuO 186, $C_{16}H_{33}O$ 212, $PhCH_2O$ 107, *p*-$NO_2C_6H_4CH_2O$ 38. *p*-HOC_6H_4OMe and cetyl iodide with MeONa give 80% of *4-cetyloxyanisole* (I), m. 68.5°; 3,4-$O_2N(MeO)C_6H_3OH$ gives 80% of *2-nitro-4-cetyloxyanisole* (II), crystg. as prisms, m. 62.5°, and needles, m. 63.9°. *3-NO_2 deriv.* (III), m. 49.5° (63% yield). At 230° a mixt. of II and III was unattacked by 10% KOH after 4 hrs.; addn. of PrOH and reheating at 140° for 4 hrs. caused slow hydrolysis. Data are given on the f. ps. and m. ps. of mixts. of II and III, contg. from 69.85% to 46.7% III. Nitration of I at 25° gives 97% of a mixt. contg. 67.8% III; at 0° the yield is 98% of a mixt. contg. 67.9% III; details of the nitrations are given. *4-Benzyloxyanisole* (IV) seps. from EtOH as plates, m. 69.7°, which are unstable and change to needles, m. 71.5° (95% yield); *2-NO_2 deriv.* (V), light yellow, m. 59.8° (80% yield); *3-NO_2 deriv.* (VI), yellow, m. 61.3° (50% yield); the m.-p. curve for mixts. of V and VI is given; the mixts. were viscous and reproducible f. ps. were not obtainable. Nitrations of IV at 28° gives 97% of a mixt. contg. 51% VI; at 14°, 97% of a mixt. contg. 51.4% VI. Details of the nitrations are given. C. J. W.



Heteropolar carbon compounds. XIII. Action of the nitro group on the salt color of positive ions. W. DILTHEY, C. BLANKENBURG, W. BRANDT, W. BRAUN, R. DINKLAGE, W. HUTHWELKER AND W. SCHOMMER. *J. prakt. Chem.* **129**, 189–205(1931); cf. *C. A.* **25**, 1513.—Tables are given showing the color of many compds. in concd. H_2SO_4 and in many cases in AcOH + H_2SO_4 and in Ac_2O + $HClO_4$. The general rule is that a NO_2 group in a Ph residue adjacent to the CO group of a ketone has a bathochromic effect on the salt color. *4'-Nitrophenyl 4-biphenyl ketone*, from Ph_2, 4-$O_2NC_6H_4COCl$, $AlCl_3$ and CS_2, m. 164°; H_2SO_4 gives a yellow-orange color. *p*-$O_2NC_6H_4SPh$ and AcBr with $AlCl_3$ in $PhNO_2$ give *4-(4-nitrophenylthiol)acetophenone*, $AcC_6H_4SC_6H_4NO_2$, pale yellow, m. 119°; concd. H_2SO_4 gives an orange-red color; with BzH and MeONa there results *4'-(4-nitrophenylthiol)chalcone*, S-yellow, m. 142°; concd. H_2SO_4 gives a red-orange color; the *4-MeO deriv.*, yellow, m. 154°; concd. H_2SO_4 gives a red color; the *3,4-methylenedioxy deriv.*, yellow, m. 174°; concd. H_2SO_4 gives a red-violet color. The reaction between *p*-$ClC_6H_4NO_2$ and PhSNa in iso-BuOH gives *azodiphenyl sulfide*, orange-yellow, m. 121–2°; the concd. H_2SO_4 soln. is violet. Ph_2O and *p*-$O_2NC_6H_4COCl$ with $AlCl_3$ give *4-(4-nitrobenzoyl)diphenyl ether*, m. 121–2°, sol. in concd. H_2SO_4 with a brown-red color, gradually changing to orange; the *3-NO_2* isomer, m. 87–8° and gives a yellow color in H_2SO_4; *3-NH_2 deriv.*, analyzed as the *HCl salt*, m. 200–6° (decompn.), sol. in concd. H_2SO_4 with a yellow color (*Bz deriv.*, pale yellow, m. 127°; the *azo dye* from β-$C_{10}H_7OH$, orange-red, gives a red color in H_2SO_4). Two mols. *p*-$O_2NC_6H_4COCl$ give *4,4'-di(4-nitrobenzoyl)diphenyl ether*, m. 226°, sol. in concd. H_2SO_4 with a red-orange color; *di-4-NH_2 deriv.*, light yellow, m. 177–8°; concd. H_2SO_4 gives an orange-yellow color; *HCl salt*, colorless; *azo dye* from β-$C_{10}H_7OH$, red-orange, sol. in H_2SO_4 with a

dark red color. *4,4'-(3-Nitrobenzoyl)diphenyl ether*, m. 175°, sol. in concd. H_2SO_4 with a yellow color; *di-3-NH₂ deriv.*, greenish yellow, m. 150–1°; H_2SO_4 soln., red-orange; *azo dye* from β-$C_{10}H_7OH$, orange, sol. in H_2SO_4 with a red color. *3-(3-Nitrobenzoyl)-diphenyl sulfide*, m. 128–9°, sol. in concd. H_2SO_4 with an orange-red color; the *di-4,4'-(3-nitrobenzoyl) deriv.*, m. 229–30° and gives an orange-red color in H_2SO_4. *Di-4,4'-(4-nitrobenzoyl) deriv.*, m. 278°; H_2SO_4 gives an orange-red color. *Di-4,4'-(3-nitrobenzoyl)-diphenyl selenide*, greenish yellow, m. 221–2°, sol. in H_2SO_4 with an orange-red color; the *di-4,4'-(4-nitrobenzoyl) deriv.*, yellow, m. 267–8° and gives a deep red soln. in H_2SO_4. *4-Benzoyl-4'-nitrodiphenyl sulfide*, m. 145°; concd. H_2SO_4 soln., orange. C. J. West



Aromatic disulfides and Sugden's parachors. S. S. Bhatnagar and Balwant Singh. *J. Indian Chem. Soc.* 7, 663–8(1930).—The parachor values for several aromatic disulfides indicate that the conventional structure with 2 bivalent S atoms is correct. The following disulfides were studied and data for each were detd. at 3 or 4 different temps.: diphenyl, m. 66.5°, $d_4^{118.0}$ 1.110, γ 35.08, parachor (mean) 477.9; 4,4'-dichlorodiphenyl, m. 71.5°, $d_4^{102.3}$ 1.304, γ 39.38, parachor (mean) 550.6; 4,4'-dibromodiphenyl, m. 93.8°, $d_4^{115.0}$ 1.647, γ 40.33, parachor (mean) 575.9; 4,4'-dimethyldiphenyl, m. 46.0°, $d_4^{111.0}$ 1.068, γ 33.13, parachor (mean) 552.9; 4,4'-dimethoxydiphenyl (I), m. 73.5°, $d_4^{100.5}$ 1.139, γ 37.84, parachor (mean) 666.1; β,β'-dinaphthyl, m. 139.0°, $d_4^{144.0}$ 1.144, γ 37.20, parachor (mean) 689.6; dibenzyl, m. 71.0°, $d_4^{100.2}$ 1.085, γ 36.42, parachor (mean) 557.1; 2,2'-dinitrodibenzyl, m. 112.0°, $d_4^{15.0}$ 1.308, γ 44.81, parachor (mean) 665.7. The parachor value of I is 6.3 units lower than that calcd. for bivalent S; presumably this is due to assocn. A. F. Shepard

Action of bromine on phenols. Gustav Heller, Werner Dietrich, Theodor Hemmer, Horst Kätzel, Erhard Rottsahl and P. G. Zambalos. *J. prakt. Chem.* **129**, 211–56(1931).—The action of Br upon phenols may be divided into several categories. (*1*) *Br does not react.*—This is the case where the phenol group is protected as in 4,6,3-$Br_2(AcNH)C_6H_2OAc$; 2,4,6,3,5-$Br_3(AcNH)(O_2N)C_6HOH$ is also unchanged on heating with Br-AcOH. (*2*) *Br enters only in the nucleus.*—4,6,3-$(O_2N)_2(AcNH)C_6H_2OH$ and Br in AcOH, heated 8 hrs. on the H_2O bath, give *4,6-dinitro-3-amino-2-bromophenol*, yellow, m. 207°; *di-Ac deriv.*, m. 222°; partial hydrolysis with dil. NaOH gives the *3-AcNH deriv.*, m. 223.5°. Warming on the H_2O bath with concd. HNO_3 gives *4,6-dinitro-2-bromo-1,3-dihydroxybenzene*, golden yellow, m. 192.5–3°; 8% NaOH gives a carmine-red salt; this also results by diazotizing in concd. H_2SO_4. 2-Acetamido-4-nitroresorcinol and Br-AcOH, shaken until soln. results and allowed to stand 24 hrs., give the *6-Br deriv.*, pale yellow, m. 173–4°. 6,3-$O_2N(AcNH)C_6H_2OH$ and Br-AcOH, warmed on the H_2O bath, give *2,4-dibromo-6-nitro-3-aminophenol*, yellow, m. 199–200°; the alkali salt is orange-yellow; and *2-bromo-6-nitro-3-aminophenol*, yellow-brown, m. 230°; the structure of these compds. was established by removal of the NH_2 group. 3,5,4-$(O_2N)_2(AcNH)C_6H_2OH$ and Br-AcOH give the *2,6-di-Br deriv.*, decomps. 274.5°, the free *NH_2 compd.*, brown, m. 138°. (*3*) *In addn. to substitution some of the groups are replaced by Br.*—4,3,5-$H_2N(O_2N)_2C_6H_2OH$ and Br-AcOH, warmed 2 hrs. on the H_2O bath, give bromoanil. Energetic bromination of 4,3-$O_2N(AcNH)C_6H_3OH$ gives 2,3,4,6-Br_4C_6HOH; with 1 mol. Br in AcOH there results the *6-Br deriv.*, yellow, m. 295° (decompn.); EtOH-KOH gives *6-bromo-4-nitro-3-aminophenol*, red-brown, m. 244° (decompn.), whose structure was established by converting it into 6,4-$Br(O_2N)C_6H_3OH$, m. 113°. With more than 1 mol. Br, there also results the *2,6-Br_2 deriv.*, yellow-orange, m. 205°; *2,6-dibromo-4-nitro-3-aminophenol*, egg-yellow, m. 162.5°. 2,4-Dinitroresorcinol and a slight excess of Br in AcOH give the *6-Br deriv.*, m. 89°, a small quantity of the 5-Br deriv. and tetra-Br deriv. 4-Acetamido-6-nitroresorcinol and Br give the *2-Br deriv.*, m. 226° (decompn.). 3- and 4-Nitropyrocatechols, on energetic bromination, give the tetra-Br deriv. and tetrabromo-*o*-quinone. (*4*) *The bromination is complete and leads to Br_5C_6OH.*—This is true of 3,4-$O_2N(AcNH)C_6H_3OH$; 3,4-$O_2N(H_2N)C_6H_3OH$, on the other hand, gives bromoanil. (*5*) *Besides complete bromination there follows addn. of Br and entrance of a halogen atom in the AcNH group.*—2,4-$(AcNH)_2C_6H_3OH$ and 1 mol. Br in AcOH give the *6-Br deriv.*, m. 215°; with HNO_3 (d. 1.4) and H_2O (1:4) on the water bath, there results *2-acetamido-6-bromoquinone*, orange, m. 183°; SO_2 in EtOH gives the hydroquinone, m. 154°; excess Br gives tetrabromodiketo-R-pentene (I), m. 143–4°. Two mols. Br gives *2,4-diacetamido-5,6-dibromophenol*, crystg. with 2 mols. H_2O, m. 188.5°, anhyd., it m. 208°; HNO_3 gives *2-acetamido-5,6-dibromoquinone*, orange, m. 213°; the hydroquinone m. 188°. Four mols. Br gives *2-acetamido-3,5,6-tribromoquinone*, golden yellow, m. 198°. Excess Br gives *4-(N-bromoacetamido)-5,6-tetrabromo-2,1-ethenylaminophenol* (II), light orange, m. gradually above 210°, and I;

with 2 *N* NaOH there results *4-acetamido-5,6-dibromo-2,1-ethenylaminophenol*, m. 245°; fuming HCl gives 5,6,2,4-$Br_2(AcNH)_2C_6HOH$, m. 188.5°. 2,6-$(AcNH)_2C_6H_3OH$ and Br in AcOH give the *3,5(?)-Br₂ deriv.*, m. 208°; a *mono-Br deriv.*, m. 215° (decompn.), Excess Br gives an orange-yellow addn. product, amorphous, m. 161–3° (decompn.). which gives with AcONa *6-acetylamino-3,4,5-tribromo-2,1-ethenylaminophenol*, m. 226°.

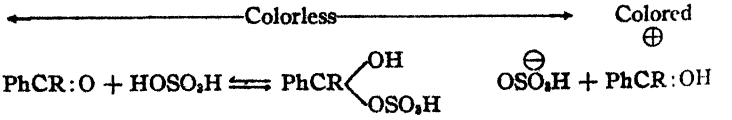
(II)

(III)

Oxidation of 2,6-$(AcNH)_2C_6H_3OH$ with HNO_3 gives *2,6-diacetamidoquinone*, orange, m. 270° (decompn.); $PhNH_2$ gives an anilide, blue-black, m. 202°; the same quinone results from 2,4,6-$(AcNH)_3C_6H_2OH$. (6) *A quinone is formed with the retention of the AcNH group.*—2,4-$(AcNH)_2C_6H_3OH$, $NaNO_2$ and dil. H_2SO_4 give *2,4-diacetamido-6-nitrophenol*, orange, m. 215°; Br in AcOH gives 2-acetamido-3,5,6-tribromoquinone. (7) *In the case of quinone formation, there generally follows complete bromination with the removal of substituents and formation of bromoanil.*—3,2,4-$H_2N(O_2N)_2C_6H_2OH$ and Br in AcOH, warmed 4 hrs. on the water bath, give the *6-Br deriv.*, yellow, m. 148° (*di-Ac deriv.*, m. 161°; *mono-Ac deriv.*, pale yellow, decomps. 221°); excess Br gives bromoanil. Through the diazo reaction in concd H_2SO_4 there results *2,4-dinitro-6-bromoresorcinol*, m. 89°. HNO_3 (d. 1.42) gives styphnic acid. 4,2,6-$AcNH(O_2N)_2C_6H_2OH$ and excess of Br give bromoanil 2,5-Dinitrohydroquinone gives the same product. (8) *Special behavior of 4,2,3,5-$H_2N(O_2N)_3C_6HOH$.*—Br in AcOH gives *5-bromo-2-nitro-1,4-quinone azide*, yellow-brown, m. 186° (decompn.); the Ac deriv. gives bromoanil. *2-Acetamido-3,5,6-trinitrophenol*, light yellow, m. 151°; Br gives a compd., m. 218° (decompn.); the free NH_2 compd. with Br gives yellow needles, exploding at 180°. (9) *In several cases the Br opens the C_6H_6 ring with the formation of tetrabromodiketo-R-pentenes.*—*4-Nitro-2-acetamidophenol*, decomps. 267°, and Br in AcOH give the *6-Br deriv.*, m. 206°; thus also results by brominating 2,4-$(O_2N)_2C_6H_3OH$, reducing and acetylating. Excess of Br in AcOH gives I and *3,5,6-tribromo-2-amino-1-quinone 4 dibromide(?)*, m. 216° (*Ac deriv.*, m. 208°). Heating 2,4,6-$AcNH(O_2N)_2C_6H_2OH$ with excess Br several hrs. also gives I. *2-Acetamido-5-nitrophenol*, m. 258–9°. 2,3,5,6-$H_2N(O_2N)_3C_6HOH$ and HNO_2 give *3,5,6-trinitro-1,2-quinone azide*, yellow, sepg. with C_6H_6 of crystn. and is very explosive; the alk. soln. gives a deep violet-red color with β-$C_{10}H_7OH$; cooking with 4–5 parts EtOH gives 2,3,5-$(O_2N)_3C_6H_2OH$; a shorter period of heating gives *3(?)-ethoxy-5,6-dinitro-1,2-quinone azide*, yellow, m. 166° (decompn.); alk. β-$C_{10}H_7OH$ gives a deep brick red dye. 2,5-Acetamidonitrohydroquinone and Br-AcOH give *2-acetamido-5,6-dibromoquinone*, orange-yellow, m. 213°, identical with that obtained on oxidation of 5,6,2,4-$Br_2(AcNH)_2C_6HOH$; an intermediate product is *2-acetamidotribromoquinone*, yellow, m. 189–90° (decompn.). *Hexaacetyl-2,5-diaminophentetrol*, $(AcNH)_2C_6(OAc)_4$, m. 216° (decompn.); 5 mols. Br give *2,5-diacetamidodihydroxyquinone*, red-brown, does not m. 280°. 3,4-$(AcNH)_2C_6H_3OH$ and Br-AcOH give the *6-Br deriv.*, decomps. 258° and the *2,6-Br₂ deriv.*, m. 223°; excess Br gives *2-methyl-5,7-dibromo-6-hydroxybenzimidazole*, greenish flakes which do not crystallize. *2,6-Diacetamidohydroquinone*, m. 240° (decompn.); Br gives *3-bromo-2,6-diacetamidoquinone*, red-brown, m. 225°; SO_2 in AcOH at 40 50° gives *3-bromo-2,6-diacetamidohydroquinone*, m. 198° (decompn.). With 5 mols. Br there results *3,5-dibromo-2,6-diacetamidoquinone*, red-brown, m. 201°; the mother liquor contains a small quantity of $(CBr_3)_2CO$; I could not be detected. (10) *Formation of hexabromoacetone:* Excess of Br-AcOH with 2,6-diacetamidoquinone gives $(CBr_3)_2CO$; this also results from nitroaminophentetrol, in addn. to $Br_2C_6(OH)_4$; a *compd.* $C_6H_3O_4NBr_2$ was obtained in some expts. *Pentaacetylnitroaminophentetrol*, m. 194°, is formed with Ac_2O and AcONa; in the presence of H_2O there results the *di-Ac deriv.*, light yellow, explodes at 214°. 2,3-$O_2N(H_2N)C_6H_2OH$ and 1 mol. Br in AcOH give the *6-Br deriv.*, m. 233°; excess Br gives the *4,6-di-Br deriv.*, yellow, m. 182°; warming with 6 mols. Br for 16 hrs. gives a mixt. of *2-dibromomethyl-4-nitro-5,6,7-tribromobenzoxazole*, m. 233°, and the *2-tribromomethyl deriv.* (III), m. 172°. Tetrabromodiketopentene and $PhNH_2$ in EtOH give *4,5-dibromo-2-dianilino-3-anil-1-ketopentamethylene*, m. 261°.

C. J. WEST

Quinone formation from nitroacetamidohydroquinone. GUSTAV HELLER AND THEODOR HEMMER. *J. prakt. Chem.* **129**, 207–10(1931).—Dinitrohydroquinone is reduced by $SnCl_2$ and HCl in AcOH to *2,5-nitroacetamidohydroquinone* (I), brick-red, decomps. 226°; the *tri-Ac deriv.* m. 183–4°. *2,5-Nitroaminohydroquinone*, red, carbonizes 154°; heating with dil. alkali gives a color change from blue through green to yellow; no characteristic substance was obtained through diazotizing. I and fuming HNO_3 in AcOH give *2-nitro-5-acetamido-3,6-dihydroxyquinone*, orange-yellow, m. 164°



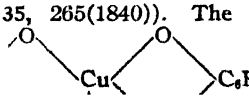
(decompn.), crystals with 0.5 mol. H_2O; with $PhNH_2$ there results *3,6-dianilino-2-acetamido-5-nitroquinone* (II), steel-blue needles, gradually decomps. at 260°. Careful oxidation of I with CrO_3 in AcOH gives apparently a *monohydroxynitroacetamidoquinone*, gradually darkens above 140°; $PhNH_2$ gives II. C. J. WEST

Halogenation of optically active phenylmethylcarbinol in the presence and in the absence of pyridine by thionyl chloride and the chlorides and oxychloride of phosphorus. JOSEPH KENYON, HENRY PHILLIPS AND FRANK M. H. TAYLOR. *J. Chem. Soc.* 1931, 382–9.—The halogenation of *l*-PhMeCHOH by $SOCl_2$, PCl_3, PCl_5 and $POCl_3$ in the presence and absence of C_5H_5N is studied. It is found that the presence of either pyridine or quinoline causes a reversal in the sign of rotation of the PhMeCHCl when $SOCl_2$ is used. When PCl_3, PCl_5 or $POCl_3$ are used in the presence of C_5H_5N, the signs of rotation of the PhMeCHCl obtained are the same as in its absence but the magnitudes of the rotations are greater. The presence of K_2CO_3 is without influence on the magnitude of the rotatory power of the PhMeCHCl obtained by the interaction of the *l*-alc. with PCl_3. It is probable that the HCl produced in the initial stage of this interaction plays no further part in the reaction and that the PhMeCHCl produced arises through the decompn. of the intermediate compd., $PhMeC(OPCl_2)H$. In the absence of C_5H_5N, which causes the inversion reaction to predominate, the decompn of the intermediate compd. appears to follow an indefinite course in which all the methods of decompn. may occur, since *d*-PhMeCHCl with $[\alpha]_{5461}$ 10.1° is obtained in place of the probably optically pure chloride with $[\alpha]_{5461}$ 64.1° which is obtained when the decompn. occurs in the presence of C_5H_5N. It would appear that, in the absence of C_5H_5N, the decompn. of the intermediate compd. PhMeC(OPOCl)H is initiated by the sepn. of a phenylmethylcarbonium cation without the simultaneous production of a Cl anion. The results of the various expts. may be tabulated as follows:

Halogenating agent		Tert. base	$[\alpha]_{5461}$ of *l*-alc.	$[\alpha]_{5461}$ of PhMeCHCl
$SOCl_2$	2 5 mols.	None	—51.7°	—63.5°
$SOCl_2$	2 0 mols.	C_5H_5N 1 mol.	49.8	17.3
$SOCl_2$	2 0 mols.	C_5H_5N 2 mols.	49.8	36.3
$SOCl_2$	2.0 mols.	Quinoline 2 mols.	43.7	16.1
PCl_3	3.5 mols.	None	51.7	10 1
PCl_3	2.0 mols.	K_2CO_3	51.7	10.0
PCl_3	2.0 mols.	C_5H_5N 1 mol.	49.8	64.1
$POCl_3$	2.5 mols.	None	28.0	0.5
$POCl_3$	2.0 mols.	C_5H_5N 1 mol.	52.1	12 6
PCl_5	2.0 mols.	None	43.7	4.5
PCl_5	2.0 mols.	C_5H_5N 1 mol.	49.8	10.4

The b. p. and *n* are given for many of the products. C. J. WEST

Salt-forming characteristics of doubly- and singly-linked elements of the oxygen groups. I. The carbonyl group in benzaldehyde and acetophenone. JOHN WM. BAKER. *J. Chem. Soc.* 1931, 307–14.—The investigation of the salt-forming characteristics of the carbonyl O in derivs. of the type ArCOR has been carried out along 2 lines The first involves investigations of the condition of such groups in H_2SO_4 soln. by the purely phys. methods of partition, colorimetry, absorption spectra, etc. Secondly, the conversion of a pseudo-basic system, directly attached to a C_6H_5 nucleus, into the "onium" salt will affect the directive action of the group causing enhanced tendency toward *m*-substitution. Pure BzH was distributed, under comparable conditions, between H_2SO_4 (of various concns.) and ligroin, both with and without the addn of $(NH_4)_2SO_4$ to the acid layer. The following results were obtained ($100[H_2SO_4]/([H_2SO_4] + [H_2O]$) and proportion of BzH in ligroin layer (%) with and without $(NH_4)_2SO_4$ are given): 7.3% free SO_2, 0.5, 1.4; 100, 0.81, 1.03; 90, 0.83, 8.7; 80, 1.77, 30.8. The equil. conditions in H_2SO_4 may be represented by the scheme:



Sol. ← —Insol. in ligroin–

In the absence of $(NH_4)_2SO_4$ these equil. are displaced largely toward the right, the BzH being retained almost completely in the acid layer, even in 80% H_2SO_4. Addn.

of $(NH_4)_2SO_4$ causes a repression of the ionic dissocn. which is followed in turn by a further decompn. of the pseudo-salt into free BzH and H_2SO_4 with the result that a larger proportion of the BzH is found in the ligroin layer. Color values of BzH in 100% H_2SO_4 at room temp. are given; in agreement with the theoretical deductions, the product *cl* is not const. as required by Beer's law, the intensity of the color decreasing with increasing diln. more slowly than this law requires. The effect of the diln. of the H_2SO_4 was investigated by detn. of the relative color intensities of solns. of BzH in 100, 90, 80 and 70% H_2SO_4 in which the mol. ratio, BzH/H_2SO_4, was kept const. If, as has been assumed, the intensity of the color is a measure of the amt. of the salt form present, then the figures show that, of the amt. of oxonium salt present in 100% H_2SO_4, 15, 55 and 79%, resp., suffers hydrolysis in presence of the same mol. quantity of H_2SO_4 but in 90, 80 and 70% diln., resp. A similar expt. with BzMe shows that hydrolysis of the onium salt occurs even more readily, the diminution in color as the strength of the acid is diminished being too rapid to admit of accurate colorimetric measurement. **II. Nitration of benzaldehyde and acetophenone in sulfuric acid solution.** J. W. Baker and Wm. G. Moffitt. *Ibid* 314–8.—Using HNO_3 of d. 1.53 at 5° the following yields of *m*-NO_2 deriv. of BzH were obtained with varying concns. of H_2SO_4: 7.3% free SO_2 90.8; 5% free SO_2 89.0; 2.7% free SO_2 89.8; 90% 86.5; 80% 83.9; 0% 72.1. With BzMe: 7.3% free SO_2 90; 80% 83.1; 0% 69.8. This establishes the anticipated increase in *m*-substitution when nitration is effected in the presence of a large excess of H_2SO_4. Proof that these compds. are nitrated mainly through the cations of the salt is afforded by the observation that the addn. of $(NH_4)_2SO_4$ depresses the *m*-substitution; Rb_2SO_4 behaves similarly. C. J. West

Inner complex salts from hydroxyaldimines and hydroxyketimines. Paul Pfeiffer, E. Buchholz and O. Bauer. *J. prakt. Chem.* **129**, 163–77(1931).—*o*-HOC_6H_4CHO and $CaCl_2$ in dil. NH_4OH give the *compd.* $(C_7H_5O_2)_2Ca\ 2H_2O$, yellow, which loses the H_2O over $CaCl_2$; the *Mg complex* also contains $2H_2O$ and is yellow. $Zn(OAc)_2$, however, gives a *complex* of *salicylaldimine*, $(C_7H_6ON)_2Zn.H_2O$, yellow; crystn. from C_5H_5N gives a compd. with 1.5 mols. C_5H_5N, which loses 1 mol on standing; the *Ni complex*, $(C_7H_6ON)_2Ni.H_2O$, red needles with golden luster, which crystallizes from C_5H_5N without solvent of crystn. The Cu complex was first prepd. by Ettling (*Ann.* 35, 265(1840)). The properties of these compds. indicate the structure

C_6H_4 Cu C_6H_4.

o-Vanillin gives a *Mg complex*, $(C_8H_7O_3)_2Mg$, yellow; a Mg salt of the imine could not be prepd. Zn gives the *complex*, $(C_8H_7O_3)_2Zn.2H_2O$, yellow; in NH_4OH there results the *complex* $(C_8H_8O_2N)(C_8H_7O_3)Zn$, which crystallizes with 0.5 mol. H_2O. Ni gives the *complex* $(C_8H_8O_2N)_2Ni$, glistening red-brown needles. *o*-HOC_6H_4Ac and $Ni(OAc)_2$ in NH_4OH, shaken 3 hrs., and the products crystd. from C_5H_5N, give the *compd.* $(C_8H_7O_2)_2Ni.2C_5H_5N$, yellowish green leaflets; when $NiSO_4$ in 25% NH_4OH is boiled 1.5 hrs., there results the *compd.* $(C_8H_8ON)_2Ni$, orange-red or dark red from C_5H_5N; from hot $PhNH_2$ it crystallizes in dark red prisms with 1 mol. $PhNH_2$. Peonol and $Cu(OAc)_2$ in EtOH give the *complex* $(C_9H_9O_3)_2Cu$, dark gray-green, which seps. with 2 mols. C_5H_5N in glistening green crystals and from $PhNH_2$ with 1.5 mols. $PhNH_2$, green. The *Ni complex* $(C_9H_9O_3)_2Ni$, green, seps. in green crystals with 2 mols. C_5H_5N and with $2PhNH_2$; this salt does not absorb NH_3. In concd. NH_4OH there results the *salt* $(C_9H_{10}O_2N)_2Ni$, brick-red, crystg. from C_5H_5N or $PhNH_2$ without solvent of crystn. in red-orange needles. Benzalpeonol and $NiSO_4$ in EtOH-NH_4OH give the *compd.* $(C_{16}H_{14}O_2N)_2Ni$, orange-red, crystg. from C_5H_5N in rust-brown needles. $AcOC_6H_4OMe$ and $NiSO_4$ in 25% NH_4OH, heated 0.5 hr., give *acetohydroquinone Me ether imine Ni* $(C_9H_{10}O_2N)_2Ni$, red prisms; it seps. with 1 mol. $PhNH_2$, in dark red crystals. C. J. West

Behavior of ketone hydrazones towards diazonium salts. M. Busch and Konrad Schmidt. *J. prakt. Chem.* **129**, 151–62(1931).—PhMeC:NNHPh (4.2 g.) in 130 cc. EtOH at −5° and 2.8 g. PhN_2Cl in 50 cc. EtOH give 4 g. of *acetophenone benzeneazophenylhydrazone* (I), orange-golden yellow, m. 161°; this is more easily formed from the phenylhydrazone in C_5H_5N, cooled to 0° and treated with concd. alc. PhN_2Cl; the *HCl salt* is a dark, brown-violet, glistening powder; reduction gives *p*-$C_6H_4(NH_2)_2$, $PhNH_2$ and BzMe. PhMeC:NNHC$_6$H$_4$Br-*p* gives *acetophenone 1-benzeneazo-4-bromophenylhydrazone*, golden yellow, m. 183°. Acetophenone *asym-m*-xylylhydrazone (II) and 2 mols. PhN_2Cl give I. *Acetophenone benzylphenylhydrazone* (III), pale yellow, m. about 58°; PhN_2Cl gives *acetophenone benzeneazobenzylphenylhydrazone*, red-yellow

oil, whose *HCl salt* is bright red. PhMeC:NNHPh and *p*-$O_2NC_6H_4N_2Cl$ in EtOH give *acetophenone p-nitrophenylhydrazone*, brown, m. 184°. *p*-$BrC_6H_4NHN:CPhMe$ and PhN_2Cl give the same product. II and *p*-$O_2NC_6H_4N_2Cl$ give *acetophenone 2-p-nitrobenzeneazo-4-nitrophenylhydrazone*, Cu-bronze, m. 300°. III and *p*-$O_2NC_6H_4N_2Cl$ give the *p-nitrophenylazophenylbenzylhydrazone* $PhMeC:NN(CH_2Ph)C_6H_4N:NC_6H_4NO_2$-*p*, brown-red, m. 130°. PhMeC:NNHPh and *m*-$(O_2N)_2C_6H_3N_2Cl$ in AcOH give *acetophenone m-dinitrophenylhydrazone*, dark brown, m. 234°. $Ph_2C:NNHPh$ and PhN_2Cl do not react; *p*-$O_2NC_6H_4N_2Cl$ gives 30% of the *p-nitrobenzeneazophenylhydrazone*, $Ph_2C:N-NHC_6H_4N:NC_6H_4NO_2$-*p*, bluish red with violet metallic luster, m. 194–6°. $Ph(PhCH_2)C:NNHPh$ and PhN_2Cl give the *compd.* $Ph(PhCH_2)C:NNHC_6H_4N:NPh$, golden yellow, m. 138° (poor yield); *desoxybenzoin p-nitrophenylhydrazone*, red with bluish violet surface luster, m. 160°, results from $Ph(PhCH_2)C:NNHPh$ and *p*-$O_2NC_6H_4N_2Cl$ or from $Ph(PhCH_2)CO$ and *p*-$O_2NC_6H_4NHNH_2$. C. J. West

The condensation of phenolic aldehydes and their ethers with methyl propyl or butyl ketones. Kenji Iwamoto and Taro Kato. *Science Repts. Tokohu Imp. Univ.*, 1st Ser., **19**, 689–93 (1930); cf. *C. A.* **22**, 575. Aromatic aldehydes with an OH or OMe group in the *p*-position condense with MeCOPr or MeCOBu to give substituted styryl Me ketones, while *m*-substituted aldehydes yield substituted distyryl ketones. *p*-HOC_6H_4CHO (2.4 g.), MeCOPr (1.8 g.) and dry HCl give 2.9 g. of *α-ethyl-p hyd* ... *styryl Me ketone* (I), faint yellow, m. 120–1°. The following styryl Me ketones were prepd. similarly: *α-propyl p hydroxy*, pale yellow, m. 100° (*oxime*, m. 110–21.5°); *α-ethyl p-methoxy* (II), faint yellow, b_{12} 171.2° (*oxime*, m. 93–4.5°); *α-propyl-p-methoxy* (III), pale yellow, b_{14} 183.4 (*oxime*, m. 191.2°). I, II and III give the CHI_3 reaction. The distyryl ketones which follow were prepd. in the same way except that coned. HCl was used in forming IV and V: *α-ethyl-m,m'-dihydroxy* (IV), brick-red, *α propyl m,m'-dihydroxy* (V), brick red, *α ethyl m,m'-dimethoxy*, dark yellow, and *α-propyl m,m'-dimethoxy*, dark yellow. A. F. Shepard

Behavior of stereoisomeric oximes of α,β-unsaturated ketones on hydrogenation. K. W. Merz. *Ber.* **63B**, 2951–3 (1930). Isovanillalacetone and $NH_2OH·HCl$ in a little MeOH give 75% (as the *HCl salt*, needles, m. 174° (decompn.)) of the *syn oxime* (*1-(3'-hydroxy-4'-methoxyphenyl) 1-buten 3-one oxime*), m. 168° which, heated 1 hr. in 12 parts AcOH on the H_2O bath, changes into the *anti form*, m. 142–3°. Both forms give by the Schotten Baumann method the same *di Bz deriv.*, m. 148–9°, hydrolyzed by boiling alc. NaOH to the *anti* oxime. The latter is not hydrogenated in alc. contg. a little AcOH by H and Pd charcoal, but the *syn* oxime (6 g.) yields a mixt. of 1.8 g. $HO(MeO)C_6H_3CH:CH_2CH_2COMe$, 1.5 g. of its oxime and 1 g. of $HO(MeO)C_6H_3CH-CH_2CH(NH_2)Me$. The same difference in the behavior of the *syn* and *anti forms* on catalytic hydrogenation was noted with PhCH:CHC(:NOH)Ph and dypnone oxime, only the *syn* forms being hydrogenated and yielding the corresponding satd. amine. It is thus shown in 2 cases that it is possible by hydrogenation to det. to which series the oximes of α,β unsatd. ketones belong. C. A. R.

Some reactions of phenyl propenyl ketone with semicarbazides and thiosemicarbazides. Alexander Y. Livingstone and Forsyth J. Wilson. *J. Chem. Soc.* **1931**, 335–7. PhCOCH:CHMe yields a *β phenylsemicarbazone*, m. 212°, even with excess of reagent; the *β phenylthiosemicarbazone*, m. 110°, becomes yellow in light without change in m. p. $NH_2NHCSNH_2$ and the ketone in HOAc–EtOH give *thiosemicarbazidopropyl Ph ketone*, m. 140°; excess of reagent gives the same product. NH_2OH gives the *oxime*, $C_{11}H_{14}ON_2S$, m. 165°. *p*-$MeOC_6H_4COCH:CHMe$ gives a *β phenylsemicarbazone*, m. 249°. C. J. West

Some synthetic bases similar to ephedrine. L. Chiriulio, Fr. Neumeier and H. Lozeron. *Helv. Chim. Acta* **14**, 186–200 (1931). ω-Hydroxy and alkoxy derivs. of ephedrine (I) were prepd. to test their vasoconstrictor action in comparison with that of I. The method of prepn. consisted of (*a*) the treatment of $PhCH:CHCH_2OH$ (II) and its Ac (III) and Bz (IV) derivs. and alkyl ethers, with I_2 and HgO, in Et_2O and (*b*) subjection of the resulting iodohydrin (without sepn.) to the action of $MeNH_2$ under pressure, at 100°. The first step is favored by light. II, III and IV (the last 2 prepd. in 70 and 60% yields, resp., by simple acylation of II) gave *di ω-hydroxyephedrine*, $PhCH(OH)CH(NHMe)CH_2OH$ (V), m. 110° (*HCl salt*, m. 159.5°). Thus step (*b*) involved a hydrolysis. In the prepn. of the alkoxy derivs. it was important to sep. the cinnamyl ethers from unchanged II; this was accomplished by benzoylation of the crude product, followed by fractionation. The intermediary compds., *cinnamyl Pr ether*, b_{12} 131.2°, *cinnamyl Bu ether*, b_{12} 138°, and *cinnamyl allyl ether*, b_{12} 138°, were prepd. by the action of the alkyl iodide on the Na deriv. of II (from II and $NaNH_2$ in C_6H_6) in 35–40%, 30–35% and 50–60% yields, resp.; the Me and Et derivs. (Et, bu

125–6°) were best obtained by means of the corresponding alkyl sulfates. The alkoxy derivs. of I obtained were *methoxyephedrine* (VI), PhCH(OH)CH(NHMe)CH_2OMe, b_{12} 148° (yield 38%) (*HCl*, m. 151–3°), *ethoxyephedrine*, b_{10} 148°, *ephedryl Pr ether*, b_{12} 151–3°, *ephedryl Bu ether*, b_{12} 155–7°, and *ephedryl allyl ether*, b_{12} 155–7°, all probably mixts. of racemates. When the reaction was conducted in MeOH instead of Et_2O, II yielded 31% of *3,3-phenylmethoxy-2-methylaminopropyl alc.*, PhCH(OMe)CH(NHMe)CH_2OH (VII), b_{11} 143°. VI was transformed into PhCH(OMe)CH(NHMe)CH_2OMe by interaction with MeI. Of the derivs. VI was the most active physiologically but it was much less active than I; in concns. of 30 mg. or more, per kg. (for a cat), its action was reversed; it lowered the blood pressure to an extent increasing with increase in concn. V had a very light constrictor action while VII produced a reversal.

I. M. Levine

β-Phenylethylamines. I. Mescaline and mescaline-like substances. K. H. Slotta and H. Heller. *Ber.* **63B**, 3029–44(1930). — In addn to the sympathomimetic action which is a general property of β-aryl-ethylamines and -ethanolamines, mescaline, 3,4,5-$(MeO)_3C_6H_2CH_2CH_2NH_2$ (I), possesses a peculiar narcotic action. For a pharmacol. and clinical investigation of I and a study of its relationships to other sympathomimetic drugs it was necessary to find a way by which it would be possible to prep. several hundred g. of I. The only method by which it had hitherto been synthesized ($RCHO$ (+ $MeNO_2$) ⟶ $RCH{:}CHNO_2$ (+ H_2) ⟶ $RCH_2CH{:}NOH$ (+ H_2) ⟶ $RCH_2CH_2NH_2$) serves to establish its structure rather than to prep. the compd. The new method should also make it possible to prep. more easily the isomers of I, as well as mono- and dimethoxyphenylethylamines, in order to det. the influence of the position and no. of the MeO groups on the physiol. action of the alkoxyphenylethylamines. An examn. of 4 other possible methods of prepn. indicated that the only feasible one was that based on the scheme $RCHO$ (+ $CH_2(CO_2H)_2$) ⟶ $RCH{:}CHCO_2H$ (+ H_2) ⟶ $RCH_2CH_2CO_2H$ (+ $SOCl_2$) ⟶ RCH_2CH_2COCl (+ NH_3) ⟶ $RCH_2CH_2CONH_2$ (+ KOBr) ⟶ $RCH_2CH_2NH_2$. The *m*- and *p*-mono- and the 2,3-, 3,4- and 3,5-di-MeO compds. have already been prepd. by this method but in all attempts to prep. I it had hitherto been impossible to carry out the last step. S. and H. have now found, however, that under certain conditions not only I but also its isomers can readily be obtained in very satisfactory yield by using concd NaOBr for the Hofmann degradation. The condensation of the aldehydes with $CH_2(CO_2H)_2$ was effected in 2–3 parts C_5H_5N (distd. over KOH) and 1–5 cc. piperidine per mol. of aldehyde; com. $CH_2(CO_2H)_2$ can be used directly and a 20% excess is quite sufficient. The splitting off of CO_2 from the primary di-CO_2H acid is almost quant. on the H_2O bath and only in a few cases was it necessary to boil the C_5H_5N soln. a short while. The yield of $RCH{:}CHCO_2H$ was in general above 80%. The reduction of the unsatd. acid was in all cases easily carried out with an excess of Na Hg, usually on the H_2O bath, a higher temp. was required only when the unsatd. acid was difficultly sol. in NaOH, and a toning down of the alky. with AcOH was necessary only with 3,4,5-$(MeO)_3C_6H_2CH{:}CHCO_2H$. The chlorides RCH_2CH_2COCl were obtained by heating the acids in $CHCl_3$ 4–5 hrs. on the H_2O bath with twice the calcd. amt. of $SOCl_2$; they were not isolated but the reaction mixts. were concd. to about 0.5 vol. *in vacuo* and added, with cooling, to concd. NH_4OH contg. about 10% NaOH (only 2,4-$(MeO)_2C_6H_3CH_2CH_2CONH_2$ could not be obtained in this way). For the successful degradation of the amides to the amines, it is necessary to have a very pure amide. The statement in the literature that NaOCl gives better yields than NaOBr was confirmed for only some of the amides (the best results were obtained with a soln. prepd. by passing 5.5 g. Cl into 40 g. NaOH in 100 cc. H_2O). The behavior of the amides in the Hofmann degradation depends greatly on the position and nature of the nucleus substituents. The products are best worked up by distn. *in vacuo*. The physiol. action of the amines prepd. will be described later by Hesse and Lange. *o*-$MeOC_6H_4CH{:}CHCO_2H$, m. 183° (80% from *o*-$MeOC_6H_4CHO$), gave 99% $MeOC_6H_4CH_2CO_2H$, m. 92° (literature, 85–6°); the *amide*, m. 111° (80.3% yield), gave with NaOCl 35.2% *o*-$MeOC_6H_4CH_2CH_2NH_2$, b. 115–20° in the vacuum of a H_2O pump (*HCl salt*, m. 143°, *sulfate*, m. 230°). *m*-HOC_6H_4CHO, m. 106° (60% by diazotization of *m*-$H_2NC_6H_4CHO$, prepd. from the NO_2 compd. with $FeSO_4$), yielded 80% of the $MeOC_6H_4CHO$ which gave 69% $MeOC_6H_4CH{:}CHCO_2H$, m. 177°; the satd. acid, m. 50° (80% yield) gave 27.5% of the amide, b_{12} 222–5°, m. 56°, which yielded with NaOBr 61% (with NaOCl 19%) of *m*-$MeOC_6H_4CH_2CH_2NH_2$, b_{12} 128°. *p*-$MeOC_6H_4CH_2CH_2NH_2$.HCl, m. 210°, was obtained in 43% yield with NaOCl from the amide which itself was obtained in 75% yield through the $MeOC_6H_4CH{:}CHCO_2H$ (82.5%) and the satd. acid (81%). *p*-iso-$PrC_6H_4CH{:}CHCO_2H$, m. 165° (64%); satd. acid, m. 73° (98%); *amide*, m. 142°

(81.5%), boils explosively with NaOCl at 80° and at 65° gives only a little *β-(p-isopropylphenyl)ethylamine*, b. 150° in the vacuum of a H_2O pump (*HCl salt*, m. 270°). Vanillin Et ether, m. 63° (85% from vanillin and alk. Et_2SO_4), gave 89% *3-methoxy-4-ethoxycinnamic acid*, m. 205°; *propionic acid*, m. 130° (79%); *amide*, m. 124° (33.9%), gave with NaOCl the ethylamine, b_{14-8} 165° (*HCl salt*, m. 120°). *m*-$C_6H_4(OMe)_2$, b_{12} 117–8° (90% from *m*-$C_6H_4(OH)_2$ with alk. Me_2SO_4), gave in Et_2O with HCN, HCl and $ZnCl_2$ 76% of 2,4-$(MeO)_2C_6H_3CHO$; 2,4-$(MeO)_2C_6H_3CH:CHCO_2H$, m. 138° (99%); propionic acid, m. 105° (94%); attempts to prep. the amide through the chloride gave a red-brown oil which decompd. on distn., *in vacuo*. 3,4-$CH_2O_2C_6H_3CH:CHCO_2H$, m. 232° (94%); propionic acid (92%); amide (83.5%), gave with NaOCl 37% of the ethylamine-HCl, m. 206°. 1,2,3-$C_6H_3(OMe)_3$, b_{12} 140° (65% with alk. Me_2SO_4), gives with HCN and $AlCl_3$ in C_6H_6 53% 2,3,4-$(MeO)_3C_6H_2CHO$, b_{12} 170°. *2,3,4-Trimethoxycinnamic acid*, m. 172° (94%); propionic acid, m. 76° (65%); *amide*, m. 171° (63.5%), gives with NaOBr 71.5% *β-(2,3,4-trimethoxyphenyl)-ethylamine*, b_{12} 167°, quickly forms the carbonate in the air. 3,4,5-$(MeO)_3C_6H_2CO_2H$ (86% from $(HO)_3C_6H_2CO_2H$ with alk. Me_2SO_4); chloride (86% with PCl_5) in boiling xylene (distd. from Na) with Pd-$BaSO_4$ and H gave in 30 hrs. 80% 3,4,5-$(MeO)_3C_6H_2CHO$, m. 74°; cinnamic acid, m. 124° (80%); *β-(3,4,5-trimethoxyphenyl)propionic acid*, m. 98° (88% yield); *amide*, m. 106° (60%), gave with NaOBr (52 g. Br and 150 g. NaOH in 375 cc. H_2O) 66% I, b_{12} 180° (HCl salt, m. 181°). *p*-BrC_6H_4OMe, b_{12} 120° (82.9% from PhOMe in AcOH with Br vapors) gave in Et_2O with Mg (activated with I) and ethylene oxide and subsequent decompn. with HCl 31.1% of *p*-$MeOC_6H_4CH_2CH_2OH$, b. 145–60° in the vacuum of the H_2O pump, and this with boiling 47.5% HBr yielded 45% of the bromide, b_{12-8} 140–50°, from which, when refluxed with a mixt. of $C_6H_4(CO)_2NH$ and 0.5 mol. K_2CO_3 until no liquid condensed in the condenser tube, then treated in alc. with $N_2H_4 \cdot H_2O$ and finally with HCl gas, was obtained 11.8% *p*-$MeOC_6H_4CH_2CH_2NH_2$ HCl, m. 211°. 4-Bromoveratrole, *p*-BrC_6H_4OH, *p*-BrC_6H_4OAc, *o*- and *p*-$BrC_6H_4NO_2$ and *o*-$C_6H_4Cl_2$ could not be made to react with Mg in either Et_2O, $(iso\text{-}Am)_2O$ or otherwise. C. A. R.

o-Toluic acid. H. T. Clarke and E. R. Taylor. *Org. Syntheses* **XI**, 96–7 (1931). Sapon. of *o*-MeC_6H_4CN with 75% H_2SO_4 gives 80–9% of *o*-$MeC_6H_4CO_2H$, m. 102–3°. *p*-$MeC_6H_4CO_2H$ is obtained in the same yield by the same method. C. J. West

Preparation of aromatic acid amides. C. H. Kao and Shao-Yuan Ma. *J. Chem. Soc.* **1931**, 443–4. cf. *C. A.* **25**, 1230.—If 100 g. aromatic acid and 150 cc. 90% AcOH are used with 90 g. $(NH_4)_2CO_3$ the following yields of amides are obtained. *p*-$O_2NC_6H_4CO_2H$, 60 g.; *m*-NO_2 deriv., 58 g.; *o*-NO_2 deriv., 15 g.; *p*-Cl deriv., 79 g.; benzilic acid, 77.5 g. (71 g. with 60 g. $(NH_4)_2CO_3$). $C_6H_4(CO)_2O$ (60 g.), 90 g. imide; *o*-$HOC_6H_4CO_2H$, 0; $PhCH_2CO_2H$ and $PhCH_2CH_2CO_2H$ give the amides quantitatively, which are in part dehydrated to the nitriles; $PhCH:CHCO_2H$ (100 g.) gives 20 g. amide. $(CH_2CO_2H)_2$ (100 g.) gives 71 g. of the imide. C. J. West

Nitration of 6-methoxy-*m*-toluic acid. A correction. John L. Simonsen. *J. Chem. Soc.* **1931**, 444.—Nitration of 3,6-$Me(MeO)C_6H_3CO_2H$ gives the 5-NO_2 deriv and 5-nitro-*o*-tolyl Me ether, m. 69–70°, and not the 6-NO_2 deriv., as reported in *C. A.* **13**, 127. C. J. West

A method for the preparation of phenyl-, *o*-chlorophenyl- and *p*-chlorophenylmalonic acids. D. Ivanoff and A. Spassoff. *Bull. soc. chim.* [4], **49**, 19–23 (1931). Grignard syntheses designed to produce ketones frequently give hydrocarbons and a complex (I) instead. I. and S. made use of I in synthesizing phenyl- (II), *o*-chlorophenyl- (III), and *p*-chlorophenyl-malonic acids (IV) according to the scheme: $PhCH_2CO_2MgX + RMgX \longrightarrow PhCH(MgX)CO_2MgX$ (I) + RH; I + $CO_2 \longrightarrow PhCH(CO_2MgX)_2$, which on hydrolysis yields II. I. and S. found that all aliphatic, aryl aliphatic and hydroaromatic, but only certain aromatic organomagnesium compds reacted in the above manner, and they have studied the reaction quantitatively to find out which gives the best yields. With $PhCH_2CO_2MgCl$ the yields of mixed acids (in g.) and of II (in %) from the following Grignard reagents were, resp.: EtMgBr, 15.25, 62.5; PrMgCl, 11.90, 45; iso-PrMgCl, 14.10, 65.6; iso-PrMgBr, 10.90, 48.9; BuMgBr, 11.00, 42.2; $C_5H_{11}MgBr$, 9.8, 40; *o*-MeC_6H_4MgBr, 11.80, 50.6; α-$C_{10}H_7MgBr$, 13.00, 53.3; $PhCH_2MgCl$, 12.40, 3.1. MeMgI gave a little gas evolution but hardly a trace of II. The procedure in all cases was to treat 0.1 g. mol. of the Grignard reagent (*e. g.*, $PhCH_2CO_2MgCl$) in 100 cc. ether at 0° with dry CO_2 in excess in a closed system, expel the excess CO_2 by evapg. half the ether, add 0.16 g. mol. of the 2nd Grignard reagent (*e. g.*, EtMgBr), reflux on the water bath, treat again with dry CO_2 in excess at 0°, hydrolyze, ext. the org. acids with ether, ext. the org. acids from the ether with dil. alkali, acidify, ext. again with ether, dry and weigh. This product contains

the corresponding phenylmalonic acid phenylacetic acid and the acid from the 2nd Grignard reagent. A weighed sample heated to 150–60° in a flask gave CO_2 and the corresponding phenylacetic acid. The wt. of CO_2 collected gave the % of the corresponding phenylmalonic acid. Only the phenylmalonic acids are sol. in benzene and can be sepd. easily in the pure state by extn. with benzene. With *o*-$ClC_6H_4CH_2CO_2MgCl$, iso-PrMgCl gave 10.5 g. mixed acids and 46.2% III; PhMgBr gave 10.5 (?) g. mixed acids and 52.8% of III. III m. 139° (decompn.); heating quantitatively produces CO_2 and *o*-$ClC_6H_4CH_2CO_2H$. With *p*-$ClC_6H_4CH_2CO_2MgCl$ iso-PrMgCl gave 13.5 g. mixed acids and 56.4% of IV; *o*-MeC_6H_4MgBr gave 13.0 g. mixed acids and 48.3 g. IV. IV m. 163° (decompn.) and on heating yields quantitatively CO_2 and *p*-$ClC_6H_4CH_2CO_2H$. The hydrocarbons evolved in the prepn. of I by the use of EtMgBr, PrMgBr, and iso-PrMgBr were collected, washed free of ether with concd. H_2SO_4 and burned with excess O for quant. detn. The amts. found checked very well with those calcd.

ODEN E. SHEPPARD

Dibenzylsuccinic acids. P. CORDIER. *Compt. rend.* 192, 361–3(1931).—Stobbé (*Ber.* 27, 2406(1894); 37, 2241, 2666(1904); *C. A* 3, 438, 651) prepd. dibenzylsuccinic acid, $[CH(CH_2Ph)CO_2H]_2$, and reported obtaining 2 isomeric acids: the one (m. 203°) (I) he considered inactive by internal compensation and the other (m. 204°) racemic. Further, S. indicated that the inactive compd. gave an anhydride m. 104° (II) which under the action of heat yielded an anhydride m. 128° (III); while the *dl*-compd gave an anhydride m. 155° which under the action of heat yielded an anhydride m. 140°. Following the same procedure, C obtained I, which gave 2 anhydrides, the first (II) being obtained by moderate treatment with Ac_2O, and the second (m. 125°) (IV) by more vigorous treatment of II. His 2nd anhydride (IV) seemed to correspond to the III of S. However, it did not give the original dibenzylsuccinic acid on hydration but a new isomeric acid (m. 172°) (V) which could easily be converted back to IV. C. found that I was inactive and could not be resolved into active components by strychnine sulfate; V was also inactive but it gave, by the same treatment, 2 active components, the one with α_d −29.5°, the other, less pure, with α_d 22.8°. These last 2 acids are much more sol. in water than V, and the m. ps. are much lower (about 130°).

ALBERT L. RAWLINS

Esters of orthophenylacetic acid. PETER P. T. SAH, SHAO YUAN MA AND CHUNG HSI KAO. *J. Chem. Soc.* 1931, 305–7. —$PhCH_2CN$ and abs. MeOH (EtOH) in an equal vol. of abs. Et_2O with 1.25 mols. HCl at 0° give 85% of $PhCH_2C(OMe):NH.HCl$ (or the Et deriv.), with 2 mols. abs. alc at room temp. for 2 weeks, there results 40–5% of $PhCH_2C(OMe)(OR)_2$ (I) or $PhCH_2C(OEt)(OR)_2$ (II); they are colorless liquids with a pleasant odor. Derivs. of I (R =) (b. p. at atm. pressure, d_4^{20} and n_D^{20} are given): *Me*, 216–8°, 1.0651, 1.5075; Et, 224–6°, 1.0356, 1.5000, *Pr*, 239–42°, 1.0109, 1.4950; *iso-Pr*, 227–9°, 1.0079, 1.4913, *Bu*, 254–7°, 0.9953, 1.4911; *iso-Bu*, 245–8°, 0.9929, 1.4898; *iso-Am*, 260–5°, 0.9880, 1.4900. Derivs. of II: *Me*, 217–9°, 1.0640, 1.5080; *Et*, 225–7°, 1.0308, 1.4997; *Pr*, 238–41°, 1.0094, 1.4967; *iso-Pr*, 228–30°, 1.0050, 1.4908; *Bu*, 254–7°, 0.9974, 1.4916; *iso Bu*, 248–51°, 0.9867, 1.4883; *iso-Am*, 260–5°, 0.9867, 1.4887.

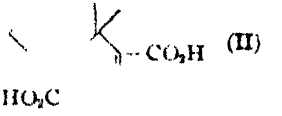
Lichen substances. VI. Gyrophoric acid. YASUHIKO ASAHINA AND MASATOSI WATANABE. *Ber.* 63B, 3044–8(1930); cf. *C. A.* 23, 4477. —The conclusion that gyro-

...oaria pulmonaria Hoffm.) ... hitherto generally been given as the m. p.). Titration of the $I.H_2O$ in Me_2CO with bromothymol blue as indicator gave a mol. wt. of 477.5–7.8 (a parallel titration with hexanoic acid gave 340.1). *Tetra-Ac deriv.* of I, from I, Ac_2O and a drop of concd. H_2SO_4, m. 228°, gives no color in alc. with $FeCl_3$ or bleaching powder soln., mol. wt.



(by titration) 626.6–641.1, in camphor (Rast) 617–32. ***Tetra(chloroacetyl) deriv.,*** from I in C_5H_5N and $ClCH_2CO_2H$ treated alternately with C_5H_5N and $ClCH_2COCl$, cryst. powder with 2 H_2O, m. 163–4°, gives no color in aq. Me_2CO with $FeCl_3$ or bleaching powder, mol. wt. (anhyd.) in boiling Me_2CO 704–815. ***Quinine salt*** of I, faintly yellowish cryst. powder with 1 H_2O, m. 162°, mol. wt. (anhyd.) in boiling Me_2CO 766.2–789.7. Me tetramethylgyrophorate (0.6 g. from 1 g. I in Et_2O with CH_2N_2), m. 196–7° (previously given as 187°), insol. in Na_2CO_3, gives no color in alc. with $FeCl_3$ or bleaching powder, mol. wt. in freezing PhOH 510.4. Since, according to Hesse, umbilicaric acid, $C_{24}H_{19}O_9(OMe)$ (II), which is also found with I in many *Gyrophorae*, is decompd. by $Ba(OH)_2$ into CO_2, orcinol and umbilicarinic acid, isomeric with evernic acid, the relation of I to II seems to be the same as that of lecanoric acid to evernic acid, *viz.*, $^{3}Me(HO)(XO)C_6H_2{}^{1}{}^{4}CO.OC_6H_3{}^{2}Me(OH)^{1}{}^{4}CO\ OC_6H_2{}^{2}{}^{6}Me(OH)^{1}CO_2H$, where X = H for I and Me for II. Also in *J. Pharm. Soc. Japan* **51**, 104–9(1931). C. A. R.

Symmetrical and unsymmetrical *o*-phthalyl chlorides. ERWIN OTT. *Org. Syntheses* **XI**, 88–91(1931). *o*-$C_6H_4(COCl)_2$ results from $C_6H_4(CO_2)O$ and PCl_5 in 92% yield. $AlCl_3$ gives 72% of the unsym. chloride. C. J. WEST

Higher terpene compounds. XLIII. The Bouveault reduction of the esters of agathic- and isoagathicdicarboxylic acids. Transformation of the latter into a new methylpimanthrene. L. RUZICKA AND J. R. HOSKING. *Helv. Chim. Acta.* **14**, 203–19 (1931); cf. *C. A.* **25**, 1232.—R. and H. suggest I and II as the skeleton formulas for agathic- (**III**) and isoagathicdicarboxylic acids (IV). The facts upon which these formulas are based are as follows: (*a*) I yields 1,5,6-$C_{16}H_4Me_3$ (V) and 1,7-dimethylphenanthrene (VI) upon reduction with Se. II also yields VI but no V. (*b*) The 2 CO_2H groups in III are different; one of the CO_2Me groups in the di-Me ester of III is easily hydrolyzed, while the other resists hydrolysis. The esters of IV, noragathic acid (VII), and isonoragathic acid also resist hydrolysis. (*c*) Upon reduction of III with Na in alc. at 115–20° a mixt. was obtained of which 30% was neutral and 70% acidic. Of the neutral portion 28% consisted of *mono-Me hydroxydihydroagathate*, $C_{18}H_{30}(CO_2Me)CH_2OH$, $b_{0.5}$ 193.5°, d_4^{16} 1.026, n_D^{15} 1.5076, M_D 97.57, (calcd 97.47). The remaining 2% contained *dihydroxydihydroagathene*, $C_{18}H_{30}(CH_2OH)_2$, m. 112.5°, which absorbed 1 mol. of H_2 in the presence of PtO to give the satd. compd. *dihydroxytetrahydroagathene*, $C_{18}H_{32}(CH_2OH)_2$, m. 107.8°. The acidic portion was distd. *in vacuo* and yielded the Me ester of VII; upon repeated redistn. of the acidic portion of the distillate *mono-Me dihydroagathicdicarboxylate*, $C_{18}H_{30}(CO_2Me)CO_2H$, $b_{0.1}$ 210.2° was obtained. The stability of this compd. in comparison to that of its precursor, $C_{18}H_{28}(CO_2Me)CO_2H$ (VIII), illustrates the effect of the double bond in close proximity to the CO_2H group. VIII contains a double bond which is easily reduced, close to a CO_2Me group which is also easily reduced and hydrolyzed. This indicates that the C atoms on either side of the double bond are unsubstituted. Reduction of the di-Me ester of IV with Na and alc. yields *Me hydroxyisoagathate*, $C_{18}H_{28}(CO_2Me)CH_2OH$ (IX), m. 125.6°, and *dihydroxyisoagathene*, m. 172.3°, in almost equal amts. A small quantity of a dehydro deriv. of IX, $C_{21}H_{30}O_3$, $b_{0.4}$ 186–90°, was also isolated. Treatment of IX with 4 vols. of 99% HCO_2H yields a mixt. ($b_{0.4}$ 155.8°) of the esters $C_{19}H_{31}(CO_2Me)Me$ and $C_{18}H_{28}(CO_2Me)Me$. This mixt. when reduced with Se yielded $C_{19}H_{14}$ (X), m. 142–3° (*picrate* m. 161.3°). Oxidation of X with CrO_3 gave the *quinone*, m. 194°, from which the *quinoxaline compd.*, m. 131.2°, was obtained. It is believed that X is a homolog of VI. **XLIV. The constitution of pimanthrene.** L. RUZICKA, G. B. R. DE GRAAFF AND J. R. HOSKING. *Ibid* 233–9.—Pimanthrene (**XI**) and retene (**XII**) were each oxidized in parallel expts. with $K_3Fe(CN)_6$ and KOH, and the mixt. of resulting acids, sepd. by means of cold MeOH, was esterified with CH_2N_2. In both cases *tri-Me 1,2,1',3'-biphenyltetracarboxylate* (**XIII**), m. 153–4°, and *1,7-phenanthrenedicarboxylic acid*, m. 151–2°, were formed. Likewise the *o*-quinones of XI and XII were oxidized with $KMnO_4$. The XII quinone yielded *3'-hydroxyisopropyl-1,2,1'-*

(I)

(II)

biphenyltricarboylic acid (XIV), m. 188° (Bucher, *C. A.* **4**, 1465, obtained the same compd. in a similar fashion but he gave no m. p.), and an amorphous substance which gave upon further oxidation with HNO_3 (d. 1.5) and esterification of the product, 1,2,3- (XV) and 1,2,4-$C_6H_3(CO_2Me)_3$. The XI quinone and XIV upon oxidation yielded XIII and XV. From these facts it is concluded that XI is 1,7-dimethylphenanthrene.
I. M. Levine

Catalytic influences in three-carbon tautomerism. II. The action of acid catalysts on ketones. George A. R. Kon. *J. Chem. Soc.* **1931**, 248–51; cf. *C. A.* **23**, 4454.—The action of H_2SO_4, HCl and $(CO_2H)_2$ on cyclohexylidene- (I) and cyclohexenylacetone and on isopulegone is reported. The acids are less rapid in their action than the catalysts previously employed; *e. g.*, *N* aq. EtOH-H_2SO_4 at 25° produces only 22% change in I in 4 hrs., which is equiv. to about 4-min. treatment with *N* EtONa. Longer treatment gives rise to extensive side reactions (addn.); at 100°, however, isomerization proceeds smoothly and side reactions are negligible in the time required to reach equil. Heating for 0.5 hr. is sufficient to produce the same equil from either ketone by means of *N* H_2O-EtOH-H_2SO_4. With HCl the same equil. p. is reached but side reactions occur more readily and a Cl-contg. high-boiling fraction is obtained. $(CO_2H)_2$ is much slower in action. The new value for the equil. p. is 23% of α,β-ketone. Isopulegone is rapidly isomerized to pulegone by hot alc. H_2SO_4, the equil. p. being coincident, within exptl. error, with pure pulegone. Although pulegone is readily isolated from the equil. mixt. as the semicarbazone, its phys. properties differ somewhat from those of pure pulegone and it may be that the equil. of isopulegone is a less simple process than hitherto supposed. Results of 18 expts are given in tabular form. C. J. W.

The energy value of the ozonide linkage determined from the ozonide of α-terpineol. E. Briner, M. Mottier and H. Paillard. *Helv. Chim. Acta* **13**, 1030–5 (1930).—Comparison of the heats of combustion of a compd. and its ozonide would give the energy equiv. of the ozonide linkage. The heat of formation would appear to be strongly exothermic since the ozonization of C_2H_4, etc., is accompanied by a considerable rise in temp. but this rise may be due to decompn. of the ozonides as well as to the heat of formation of the ozonide. For the detn., the ozonide of α-terpineol I) was chosen because it is stable and a solid I was ozonized in specially dried hexane (II), the II was then decanted off and the I ozonide was placed in a vacuum desiccator to remove the residual II. Small quantities of an unidentified gas were continuously given off and it was found that the heat of combustion decreased as the age of the ozonide increased. The av. heat of combustion of freshly prepd. I ozonide was 1445 cal. per g mol and that of I was 1501 cal., from which the heat of ozonization of I was found to be 90 cal. This value is probably significant though not rigorously exact. Since it indicates a lower energy content than that of the components which enter into the ozonides, there would appear to be no advantage in the suggested employment of ozonides as explosives unless ozonization alters the mol. to make disuption of its linkages easier. C. H. Peet

Oil of Eucalyptus dives. K. Stephan and Marg. Ducker. *J. prakt. Chem.* **129**, 147–50(1931).—The oil from *Eucalyptus dives* contains 55% of piperitone; the oil also contains about 4.5% of terpinen-4-ol and also an *acid*, $C_{11}H_{16}O_3$, m. 109–12°. Oxidation of piperitone with $FeCl_3$ gives 90% of thymol, oxidation with neutral $KMnO_4$ gives dosphenol, but the yield is too small to make this a technical method of prepn. C. J. West

Thiobenzophenone. H. Staudinger and H. Freudenberger. *Org. Syntheses* **XI**, 94–5(1931). Ph_2CCl_2 and NaSH in EtOH give 42.9% of Ph_2CS, m. 53–4°; if the chloride is added to the NaSH a 70% yield of the disulfide is obtained. C. J. West

4-Nitro-4'-methoxystilbene. A correction. J. T. Hewitt and Wm. Lewcock. *J. Chem. Soc.* **1931**, 444 –4-Nitro-4'-methoxystilbene m. 132°, not 162° as reported in *C. A.* **6**, 3264. C. J. West

α-Chloronaphthalene. V. The chlorination of naphthalene in solution. P. Ferrero and J. Corbaz. *Helv. Chim. Acta* **13**, 1009–25(1930); cf. *C. A.* **22**, 2938; **23**, 4944; **24**, 100, 1652.—The study of the chlorination of $C_{10}H_8$ (I) was continued in a variety of solvents to establish, if possible, a series which would either be protected by the chlorination product or which would prevent the chlorination of I. In every case, 2 mols. of I was dissolved in 500 g. of solvent and Cl_2 passed in at the rate of 35 g. per hr. When a catalyst was used, a wt. was taken equal to 0.5% of the I present. Below the limits at which partial oxidation occurs, higher temps. favor monohalogenation. I_2 always favors monohalogenation while $FeCl_3$ favors polyhalogenation. The concn. mentioned above was about the optimum, less solvent approaching the condition of no solvent with consequent polyhalogenation and more solvent resulting in gradual

chlorination of the solvent and polyhalogenation of I. The theoretical amt. of Cl_2 should be added but the rate of addn. is immaterial so long as the Cl_2 is thoroughly dispersed throughout the reaction mixt. *The chem. nature of the solvent is more important than the amt. present or the phys. properties of the soln.* Solvents which cannot be acted upon by Cl_2 (*e. g.*, CCl_4) favor a considerable formation of poly-Cl derivs. and are less desirable than no solvent. Solvents which might be chlorinated (*a*) (*e. g.*, PhH or PhCl) may be protected from chlorination by the I even in the presence of I_2 and are the most satisfactory solvents for use in chlorination or (*b*) (*e. g.*, PhMe or $C_{10}H_{18}$) they may protect the I against chlorination and hence be entirely unsatisfactory solvents. PhH, PhCl and AcOH are the most satisfactory solvents investigated. PhMe, *o*-$C_6H_4Cl_2$, $PhNO_2$, $C_2H_2Cl_4$, C_2HCl_3, EtOH, AcOEt and Et_2O are all unsatisfactory for reasons mentioned above. C. H. Peet

Naphthalene series. III. Preparation of 3-amino-2-naphthyl methyl ether. Gev Bamanshaw Jambuserwalla, Sidney Holt and Frederick A. Mason. *J. Chem. Soc.* 1931, 373–7; cf. *C. A.* 19, 497.—2,3-$HOC_{10}H_6CO_2H$ (48 g.) in 100 cc. 20% NaOH with 64 g. Me_2SO_4 at 15° gives 49.6 g. of *2-methoxy-3-naphthoic acid*, pale yellow, m. 133–5°; the use of too great excess of alkali decreases the yield; the chloride is a transparent yellow gum, m. about 59° (decompn.), which gives with $(NH_4)_2CO_3$ in C_6H_6 77% of *2-methoxy-3-naphthamide*, m. 172–3°; 15 g. of the amide in EtOH, treated with KOBr, gives not over 3 g. of 3,2-$H_2NC_{10}H_6OMe$, m. 109–10°. The diazo compd. with CuCl gives 82% of *3-chloro-2-naphthyl Me ether*, m. 78.5°; HI gives *3-chloro-2-naphthol*, m. 63–4.5°, gives a green color with $FeCl_3$. 2,3-$MeOC_{10}H_6CO_2Et$, b_{18} 198°, gives 98% of *2-methoxy-3-naphthhydrazide* (I), m. 121–4°; it melted slowly when heated on the H_2O bath and then m. 137–8°; with 2,3-$MeOC_{10}H_6COCl$ there result 80% of *di (2-methoxy-3-naphth)hydrazide*, m. 248–50°. I and BzH give the *benzylidene deriv.*, m. 222.5° (cor.); *m-nitrobenzylidene deriv.*, canary-yellow, m. 223–4° (cor.); *o-isomer*, canary-yellow, m. 185–6° (cor.); I and vanillin give *4'-hydroxy-3,2'-dimethoxybenzylidene-3-naphthhydrazide*, m. 211–2° (cor.). I in EtOH-HCl with EtNO$_2$ gives 72% of *Et 2-methoxy-3-naphthylcarbamate*, m. 104–5° (cor.); hydrolysis with concd. HCl at 120° for 3 hrs. gives quant. 3,2-$H_2NC_{10}H_6OH$; 10% H_2SO_4 gives the naphthol and some Me ether; heating with slaked lime for 3 hrs. at 200° gives 85% of the Me ether; 40% NaOH on refluxing 1 hr. gives 92.5% of the Me ether. IV. **Preparation and properties of 2-naphthol-3-sulfonic acid.** S. Holt and F. A. Mason. *Ibid.* 377–81.—3,2-$H_2NC_{10}H_6OMe$ (14 g.) was diazotized in a mixt. of 48 cc. concd. H_2SO_4 and 160 cc. H_2O at 0° with 2 *N* $NaNO_2$; SO_2 was passed into the diazo soln. until frothing became noticeable and 10 cc. liquid SO_2 were then run in; chem. prepd. Cu powder (30 g.) was then added, a slow stream of SO_2 being maintained; the ppt. was then extd. with 30% K_2CO_3 and the ext. acidified with concd. HCl, giving nearly quant. *2-methoxynaphthalene-3-sulfinic acid* (I), m. 133–4°. Oxidation with $KMnO_4$ in Me_2CO gives nearly quant. the *K salt* (II) of the SO_3H acid; oxidation in H_2O gives 75% of a less pure product. The alk. soln. of the salt gives no color with 2,4-$(O_2N)_2C_6H_3N_2Cl$. *2-Methoxynaphthalene-3-sulfonyl chloride* m. 137–8°; the amide m. 113°; the *anilide* m. 173–4°. I and 2,4-$(O_2N)_2C_6H_3Cl$ in EtOH-AcONa give *2,4-dinitrophenyl 2-methoxy-3-naphthyl sulfone*, m. 213–4°. II and HCl (1:1), refluxed 1 hr., give 93 of *2-naphthol-3-sulfonic acid* (III), which sepa. with 1 mol. H_2O; the *Na salt* also sepa. with 1 mol. H_2O; the chloride is amorphous; the $PhNH_2$ salt m. 241–2°; the α-$C_{10}H_7NH_2$ salt m. 247–8°; the sulfonamide, yellow, m. 110°; 2-naphthol 3-sulfonanilide, buff, m. 112° (decompn.). *1-Nitroso-2-naphthol-3-sulfonic acid*, yellow, decomps. 268°; $FeCl_3$ gives a deep brown color; it dyes Fe-mordanted cotton a tobacco-brown. III yields azo dyes as follows: *$PhNH_2$*, red needles with blue reflex; *p-$O_2NC_6H_4NH_2$*, red needles; *m-xylidine*, red powder; *α-$C_{10}H_7NH_2$*; *dianisidine*. Dyeings with these on wool were deeper in all cases than the corresponding shades obtained from Schaffer acid. The peaks of the absorption curves of these dyes are given. C. J. West

Alkamines and ether bases of the tetralin and hydrindene series. Julius v. Braun and Karl Weissbach. *Ber.* 63B, 3052–9(1930).—It was recently shown (*C. A.* 25, 1812) with $CH_2O_2C_6H_3CH(OH)CHBrMe$ (I) that it is possible to det., by methylation with Me_2SO_4, whether in the alkamines formed (through the α-oxide) by treating I with an amine RNH_2 the RNH is in the β-position originally occupied by the Br and the OH in the α-position, as in the I, or whether, when the intermediate α-oxide ring is opened, the NHR group goes to the α-position and the HO to the β position. This method has now been used to answer the long unanswered question as to the structure of the alkamines (II) obtained from α,β-dibromotetralin through the bromohydroxy compd. with various amines. Methylation of the alkamine obtained

with $NHMe_2$ and treatment with KI gives a *quaternary iodide* (III) different from that (IV) obtained by replacing the Br in α-methoxy-β-bromotetralin by NMe_3 and adding MeI. While IV decomps. into a tertiary base and MeI on heating, III gives NMe_2·HI and the *Me ether* (V), C_6H_4·CH:C(OMe)·CH_2·CH_2, of the enol form of the tetralone; V readily takes up 2 atoms H and on dehydrogenation with Br yields β-$C_{10}H_7OMe$, showing that in the II the HO occupies the β-position. Analogous expts. in the indene series showed that, contrary to the hitherto generally accepted view, the alkamines (VI) obtained from α-hydroxy-β-bromohydrindene have the HO group in the β-position. Partly to confirm these results by a different method, and partly to obtain the α-HO isomers of the I and VI for pharmacol. comparison with the I, attempts were made to prep. these α-HO isomers by demethylation of the corresponding α-MeO compds. These attempts were successful only with α-methoxy-β-methylaminotetralin, the resulting alkamine (VII) being different from the II from α-hydroxy-β-bromotetralin with $MeNH_2$. When the basic substituent of the α-MeO compds. is NMe_2 or NC_5H_{10}, the only definite products of demethylation in the tetralin series are the unsatd. bases C_6H_4·CH:C(NR_2)·CH_2·CH_2 (VIII), and the analogous unsatd. bases are the chief products in the indene series even where the basic substituent is NHMe. VII, which may be considered as a cyclic ephedrine, acts pharmacologically like ephedrine, although not as powerfully. III, m. 168°. V, b_{14} 136°, d_4^{27} 1.0674, turns yellow and thickens on standing several weeks, gives the same blue color as β-tetralone when shaken in alk. soln. in the air, gives the tetralone, m. 132–3°, when shaken several hrs. with 2 *N* HCl, is reduced by H and Pd to *ac-β-tetralyl Me ether*, b_{14} 123–4°. *α-Methoxy-β-dimethylaminotetralin*, from the β-Br compd. and $NHMe_2$ in C_6H_6 at 100°, yellow, b_{13} 147–9° (30% yield); *HCl salt*, m. 184°; *picrate*, m. 192°; *methiodide* (IV), m. 210°, depresses the m. p. of III to 135–48°. *α-Methoxy-β-methylaminotetralin* (50% yield), b_{14} 144–6°; *HCl salt*, m. 228°; *picrate*, m. 150°. Exhaustive methylation of the base gives IV. *α-Methoxy-β-piperidinotetralin*, b_{14} 191–3°; *HCl salt*, m. 230°; *picrate*, m. 153°. *α-Hydroxy-β-methylaminotetralin* (VII) (60% from the α-MeO compd. with 66% HBr at 55–60°), m. 77–9° (*HCl salt*, m. 206°); if the heating with HBr is carried out at 100°, the product is the *unsatd. base*, b_{12} 162–4°, of the type VIII; it forms a hygroscopic *HCl salt*, m. 148–50°, and a yellow *picrate* m. 149°. The unsatd. *dimethylamino base* (VIII), $b_{0.4}$ 102–4°, is obtained even when the temp. in the heating with HBr is not raised above 40–5°, it darkens and thickens in the air and forms an oily HCl salt and a *picrate* m. 148°. The *piperidino analog*, $b_{0.4}$ 168–70°, m. 40°, is likewise formed at 40–5°; *picrate*, yellow, m. 149°. *β-Hydroxy-α-methylaminohydrindene* (VI), m. 130°; *HCl salt*, m. 175°; *picrate*, m. 153°. Methylation with Me_2SO_4 and treatment with KI gives a quaternary *iodide*, m. 187°, which splits off NMe_2·HI only slowly and incompletely above its m. p., and gives a light yellow oil, b_{14} 114–6°, having approx. the compn. of *β-hydrindone enol Me ether* and giving β-hydrindone when shaken with H_2O. A more complete decompn. can be effected by distn. *in vacuo*, which gives β-hydrindone and a base $C_{13}H_{17}ON$, regenerating the iodide with MeI and different from IX (below); it is therefore probably *α-dimethylamino-β-methoxyhydrindene*. It b_{14} 132°; *picrate*, m. 159°. The *β,α-isomer* (IX), from *β-bromo-α-methoxyhydrindene* (b_{11} 134°, obtained in 90% yield from the di-Br compd. with boiling MeOH) with Me_2NH in C_6H_6 (yield, 20%), b_{14} 128–9°, rapidly reddens, forms a *methiodide* m. 176°, which quantitatively regenerates IX and MeI on dry distn. *Methylamino analog* of IX (35%), b_{14} 127–8°, darkens even more rapidly than IX; *picrate*, m. 118°; *HCl salt*, m. 173°. Demethylation of the MeO is much more difficult than in the tetralin series; heating with concd. HBr at 100° for even only 1 hr. gives a thick non-distillable basic oil, apparently a polymerization product of the unsatd. amine, for by heating 1 hr. at 50°, treating with NaOH-K_2CO_3, extg. with Et_2O and treating in petr. ether with HCl in Et_2O there is obtained a *salt* m. 165–6° having very nearly the compn. $C_{13}H_{18}NCl_3$ of the HCl addn. product of the unsatd. amine. The *α-hydroxy-β-methylaminohydrindene*, m. 77–9°, was finally obtained in small yield by allowing the MeO compd. to stand 40 hrs. with fuming HBr at room temp. and then heating 15 min. at 45–50°; its yellow *picrate* m. 171°. IX on short heating with HBr gave a basic oil which soon began to thicken and could not be distd. C. A. R.

1-Amino-2-naphthol hydrochloride. J. B. Conant and B. B. Corson. *Org. Syntheses* XI, 8–11(1931).—1,2-$C_{10}H_6(NO)ONa$, reduced with $Na_2S_2O_4$ at 60–5°, gives 66–74% 1,2-$C_{10}H_6(NH_2)OH$. C. J. West

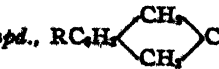
1-Amino-2-naphthol-4-sulfonic acid. Louis F. Fieser. *Org. Syntheses* XI, 12–4

(1931).—1,2-$C_{10}H_6(NO)OH$ in $NaHSO_3$ and *N* NaOH, treated with concd. H_2SO_4, gives 82–4% of 1,2,4-$H_2N(HO)C_{10}H_5SO_3H$. C. J. West

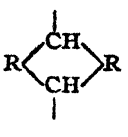
2-Iodo-3-naphthoic acid. Henri Goldstein and Ernest Cornamusaz. *Helv. Chim. Acta* **14**, 200–3(1931).—Diazotization of 2,3-$C_{10}H_6(NH_2)CO_2H$ and treatment of the product with KI gives 70% of *2-iodo-3-naphthoic acid* (I), m. 214°; *Me ester* (85% yield), m. 55°; *Et ester* (87% yield), m. 78°; *amide* (from the action of concd. NH_4OH on the impure *chloride* prepd. by treatment of I with PCl_5), m. 241° (yield 90%); anilide, m. 205° (yield 80%). I. M. Levine

Syntheses of antiseptic derivatives of indan-1,3-dione. I. Interaction of malonyl chloride and of alkylmalonyl chlorides with the methyl ethers of resorcinol and β-naphthol. Raphael Black, Herbert Shaw and Thomas K. Walker. *J. Chem. Soc.* **1931**, 272–9.—$CH_2(COCl)_2$, obtained in 36% yield from the acid and PCl_5, with *m*-$C_6H_4(OMe)_2$ and $AlCl_3$ in $PhNO_2$ gives 30% of *7-hydroxy-5-methoxyindan-1,3-dione*, lemon-yellow, m. 217°. $MeCH(COCl)_2$, b_{22} 45–50°, gives the *2-Me deriv.*, m. 225–6°; *2-Et deriv.*, pale fawn-colored, m. 192.5°; *2-Pr deriv.*, pale fawn, m. 190.5°; the Bu deriv. could not be obtained cryst. β-$C_{10}H_7OMe$ and $CH_2(COCl)_2$ with $AlCl_3$ in $PhNO_2$ give 31% of *5-hydroxyperinaphthindan-1,3-dione*, dull yellow, m. 276–80°; *2-Et deriv.*, golden brown, m. 215° (20% yield); *2-Pr deriv.*, bright canary-yellow, m. 181°; *2-Bu deriv.*, yellow, m. 185°. These compds. exert no action on *B. coli communis* when tested by the Rideal-Walker technic and they were also without effect on the proliferation of organisms of the *B. pyocyaneus* group; very definite inhibition of growth was observed with *S. pyogenes* and a no. of Gram-positive bacilli. These compds. are to be regarded as possessing selective antiseptic properties distinct from the general disinfectant properties of the phenols from which they are derived. Detailed results are given with *Bacterium C.* The introduction of an alkyl substituent into the 2-position of the dione ring in the parent resorcinol derivs. results in a lowering of the antiseptic power, but this depressing effect is counterbalanced to an increasing degree as the length of the substituent alkyl chain is increased. Such lowering effect is absent in the alkylated indandiones derived from β-$C_{10}H_7OH$. C. J. West

Anthracene derivatives. II. Edward de Barry Barnett and Norman P. Goodway. *Ber.* **63B**, 3048–51(1930); cf. *C. A.* **24**, 5036. – In order to obtain further data on the influence of substituents in the side ring on the reactions of atoms and groups in the *ms*-position, attempts were made to reduce 1,5-dimethoxyanthraquinone (I) to the corresponding anthrone, but in spite of numerous trials in both acid and alk. soln neither the anthrone nor the anthracene could be obtained. The now commercially prepd. and hence readily available 1,5-diphenoxyanthraquinone (II) also did not yield the *anthrone* (III) by either the usual Sn-HCl or the Al powder-concd. H_2SO_4 method. III was obtained in satisfactory yield, however, with $SnCl_2$ and HCl in AcOH. It was unchanged by MeMgI and $PhCH_2MgCl$; the copious evolution of gas with MeMgI pointed to the anthranol rather than the anthrone structure. Attempts to obtain a mono- or di-benzylanthrone by boiling with $PhCH_2Cl$ and NaOH gave only resinous products and unchanged III. III is readily brominated and the *10-Br deriv.* (IV) resembles 1,5-dichlorobromoanthrone more than bromoanthrone itself. It readily yields 10-RO and 10-NHR derivs. This seems to support the theory of *peri*-coördination, but in view of the contradictory results recently obtained, a theoretical discussion is reserved for a later date. With the object of detg. the influence of a β-PhO group, $C_6H_4(CO)_2O$ was condensed with Ph_2O but the resulting *4'-phenoxybenzophenone-1-carboxylic acid* (V) could not be converted into the anthraquinone. It was, however, easily reduced to *4'-phenoxydiphenylmethane-1-carboxylic acid* (VI); attempts to convert this into the anthrone have thus far failed. The I, pale yellow, m. 241°, was obtained in about 30 g. yield from 1,5-$NaO_3SC_6H_3(CO)_2C_6H_3SO_3Na$ and 1.5 parts NaOH boiled 40 hrs. with continuous stirring in MeOH. III, yellow, m. 166°, gives with C_5H_5N-Ac_2O on the H_2O bath *1,5-diphenoxyanthranyl acetate*, yellow, m. 165°. IV, yellow, m. 180–3° (gas evolution). *10-EtO deriv.*, from IV refluxed in alc. with $CaCO_3$, m. 148°, quickly turns light pink on the surface; *anthranyl acetate*, yellow, m. 238°. *10-Piperidino deriv.*, m. 136°. *10-Anilino deriv.*, yellow, m. 159° (decompn.). *10-N-Methylanilino deriv.*, yellow, m. 159°. *10-p-Dimethylaminophenyl deriv.*, faintly yellow, m. 205°. V, m. 162°. VI, from V with Zn dust and aq. NH_4OH on the H_2O bath, m. 128°. C. A. R.

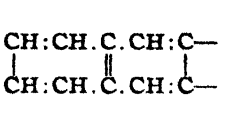


Oxalic acid as a condensing agent. I. Condensation of phthalic anhydride and phenol. S. Nakanishi. *J. Pharm. Soc. Japan* **51**, 31–4(1931); German abstr. 10–11.—$C_6H_4(CO)_2O$ (I) (10 g.), when treated with hydroquinone (5 g.) and $(CO_2H)_2$ (20 g.) at 120–40° for 2 hrs., gave *quinizarin*, $C_{14}H_8O_4$, m. 194°. I (5 g.), α-naphthol (5 g.) and



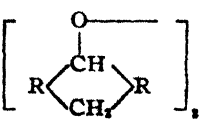
$(CO_2H)_2$ (20 g.), when treated as above, gave *α-naphthofluoran*, $C_{28}H_{16}O_3$, m. 300° (yield 3 g.). F. I. NAKAMURA

Constitution of the aloins. E. LEGER. *Bull. soc. chim.* [4], **49**, 70–2(1931).—A polemic. Cf. Gibson and Simonsen, *C. A.* **24**, 2752. ODEN E. SHEPPARD



Anthraquinhydrone. OSCAR BALLY. *Ber.* **63B**, 2938(1930); cf. Scholl and Böttger, *C. A.* **25**, 695.—In 1905 (Ger. pat. 194,252), in applying alc. KOH fusion to the prepn. of isoviolanthrone, B. observed with anthraquinone itself an intense bottle-green color. Scholl, apprised of this observation, ascribed the color to the formation of K anthraquinhydrone. C. A. R.

Polynuclear aromatic hydrocarbons and their derivatives. VII. A new class of deeply colored radical hydrocarbons and the supposed pentacene of E. Philippi; also a reply to remarks of Roland Scholl and Oskar Böttger. E. CLAR AND FR. JOHN. *Ber.* **63B**, 2967–77(1930); cf. *C. A.* **24**, 2457.—*lin*-Dibenzo-9,10-dihydroanthracene (I), when dehydrogenated by passing over heated Cu *in vacuo* or by boiling in $PhNO_2$ with phenanthrenequinone or in xylene with chloranil, gives a deep violet-blue hydrocarbon, $C_{22}H_{14}$, to which (see below) is assigned the structure of a *2,3,6,7-dibenzanthracene-9,10-diyl* (II, R = III). The homologs of I yield corresponding violet-blue hydrocarbons. These deeply colored, very difficultly sol. and high-melting hydrocarbons differ from the hitherto known condensed aromatic hydrocarbons of the same mol. magnitude not only in their deep color but also in their interesting reactions. The red xylene soln. of II is unchanged by dry O but moist O or air changes it to yellow, with green fluorescence, and ppts. an insol. colorless *peroxide* (IV), and the mother liquor on concn. yields yellow-brown needles, $C_{22}H_{14}O_2$ (V). IV has the compn. $C_{44}H_{28}O_2$ and regenerates II when heated to its m. p. or in high-boiling solvents ($PhNO_2$), properties agreeing well with the peroxide structure given. IV is then apparently formed by the addn. of H_2O_2, not of O_2. Unfortunately mol.-wt. detns. could not be made because of the insoly. of the IV. The *endocyclic peroxide* V is accompanied by varying amts. of the monoquinone $R(CO)_2R$ (VI), apparently formed by further oxidation of V. In 1 case where the di-mol. IV was not formed, the monomeric V was readily isolated in pure form. It does not dissolve in NaOH and on fusion shows the decompn. characteristic of peroxides. Light greatly accelerates the oxidation. CrO_3 and AcOH, as already reported, give VI exclusively. In xylene suspension, II is immediately decolorized by benzoquinone with the formation of a faintly yellow cryst. product to which is assigned the structure VII; on heating it does not break down into its components but melts to a dark mass, with evolution of gas. With chloranil in xylene the reaction is somewhat slower and there are obtained a yellow (VIII) and a brown-red product (IX). VIII, from its compn., is the analog of VII but on heating alone or in high-boiling solvents breaks down into its components. IX contains 1 mol. more of H_2O and does not split up into its components when heated; it is provisionally assigned the structure shown. Dil. NaOH converts it into a colorless, difficultly sol. compd., while VIII dissolves only in alc. KOH, with brown-red color. Crystn. of IX from AcOH changes it into a light-red *substance* (X) of much higher m. p. which is no longer altered by dil. NaOH. With phenanthrenequinone, II does not react; it reacts at once with halogens, including I, and readily with boiling $PhNH_2$ contg. a little $PhNH_2.HCl$. Among the reaction products with halogens are halogen-contg. diradicals of great stability. If II, which sublimes undecompd. below 300° in CO_2, is sublimed above this temp., it gives, depending on the temp., small quantities of I, m. 270°, and the residue, which retains the cryst. structure of the II, has a glittering, graphite-like appearance. It is probably formed by a graphite-like linking together of many hydrocarbon mols., while the H thereby set free reduces a part of the II to I. The properties of II indicate that it has the structure shown. Röntgen ray studies by Debye's method have established the uniplanar position of the C_6H_5 rings and leave hardly any doubt as to the correctness of the structure II. The supposed 2,3,6,7-dibenzoanthracene, which Philippi, with Scholl, Houben and de Diesbach, calls *lin*-pentacene (*C. A.* **24**, 356), is really the dihydro deriv. (I). Using their own method of prepn. (*C. A.* **24**, 1634), C. and J. obtained a hydrocarbon with the same properties as P.'s but with the compn. $C_{22}H_{16}$, not $C_{22}H_{14}$, and yielding II on dehydrogenation, and VI exclusively on oxidation. On standing some months, the m. p. of the I rises to 300–10° and the substance (XI) now agrees in all its properties with that first described by Mills and Mills; on oxidation it gives the diquinone, $C_6H_4(CO)_2C_6H_2(CO)_2C_6H_4$, although with $FeCl_3$ it gives only VI; this is readily explained by an intermediate dehydrogenation to II by the $FeCl_3$. XI, which is apparently more stable at room temp. than I, is probably formed from I by a change in position of two H atoms and is the *1,4-dihydro*



compd.,  The reverse rearrangement has been effected by heating XI for some time above its m. p. under CO_2; the resulting product with CrO_3 now gives VI along with traces of the diquinone. There is no change in compn., as P. believes, in the rearrangement. Both forms give red melts. A brief reply is made to the criticisms of Scholl and Böttger (*C. A.* **25**, 696). IV decomps. 335–60°, imparts a faint green color to concd. H_2SO_4. V, m. 320–30° (decompn.), sol. in H_2SO_4 with green color. *2,3,6,7-Dibenzanthracene-9,10-diyl hydroquinone ether* (VII), decomps. 262° with gas evolution (m. 355° with carbonization if heated very slowly). *Tetrachlorohydroquinone ether* (VIII), m. 263° (gas evolution), sol. in H_2SO_4 with dirty green color; *mono-ether* (IX), m. 267–8° (gas evolution), also sol. with dirty green color in H_2SO_4. X, apparently formed from IX by loss of 2 mols. HCl and 1 mol. H_2O, darkens 300°, m. 370° (decompn.), sol. in H_2SO_4 with violet-red color.

C. A. R.

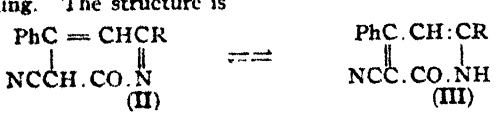
Unsaturated compounds. XII. Action of hydroxylamine on furfurhippuric acid and its esters, as also on furfuracrylic esters. Theodor Posner and Irmengard Sichert, née Modrow. *Ber.* **63B**, 3078–88(1930); cf. *C. A.* **18**, 3367.—The addn. at conjugated double bonds has hitherto been studied chiefly on variously substituted cinnamic acids. The present work deals with the influence on the additive power of the replacement of the C_6H_4 nucleus by the furan ring and the relation to the strength of the acid. *Acid addn. products.*—The furan ring increases the dissocn. of the acid and quite materially increases the difficulty of addn.; furfuracrylic acid (I) adds more difficultly than hippuric acid (II), furfurhippuric acid (III) more difficultly than benzalhippuric acid (IV) and III more difficultly than I; the increase in the yield of NH_2OH addn. products of the acids of the furan series agrees well with the decrease in the dissocn. of the acids, insofar as these consts. have been detd. On short heating the formation of hydroxamino acids, $RCH(NHOH)CH_2CO_2H$, increases with decrease in dissocn., and on longer heating the oxamino acids are more and more oxidized to the ketones. The formation of the other oxidation product, the isoxazolone, N:CR.CH_2.CO.O, and of the reduction product, $RCH(NH_2)CH_2CO_2H$, is irregular. *Ester addn. products.*—The esters add much more easily than the corresponding acids, the Et ester generally somewhat easily than the Me ester; they generally react quite well with NH_2OH in the cold, whereas the acids only form the NH_2OH salts. Unlike the acids, which add only 1 mol. NH_2OH when heated, the esters react in the cold with 2 and 3 mols. NH_2OH and the ability to add 1–3 mols. increases from the ester of the strongest to that of the weakest acid (the Me ester of III adds 1, the Et ester of IV 2, $PhCH:CHCO_2Et$ 3 mols.) Most of the cinnamic esters with HO and MeO substituents on the nucleus are exceptions; they in general do not add at all in the cold. The yield of oxime and isoxazolone increases inversely proportionally to the dissocn. consts. of the corresponding acids; only *o*-$O_2NC_6H_4CH:CHCO_2Et$ is an exception. The amino acids also are generally formed in smaller amounts the weaker the corresponding acids are (except with the esters of III, *o*-$O_2NC_6H_4CH:CHCO_2H$ and *trans*-*o*-$MeOC_6H_4CH:CHCO_2H$). The ester of III forms oxidation and reduction products even in the cold, and in spite of the slow addn. even when boiled, it yields a relatively large amount of amino acid. In the expts. at the boiling temp., esters of III, contrary to the cinnamates, form small

amounts of the free acid, and likewise some ester is formed from the free acid. III is obtained in 35 g. yield by refluxing 100 g. $BzNHCO_2H$ with fural and treating 50 g. of the resulting azlactone (obtained in 92 g. yield) in NaOH with HCl. The II, m. 187–8.5°, is obtained in 90% yield from $ClCH_2CO_2H$ and NH_4OH, followed by evapn. and treatment with BzCl in NaOH. Me ester of III, m. 141° (78 g. from 94.0 g. of the azlactone with Na in MeOH contg. a little H_2O). In the prepn. of the II there is also obtained *N-benzoyldiglycolamidic acid*, $BzN(CH_2CO_2H)_2$, m. 68°, sol. slowly in NaOH, quite difficultly sol. in HCl. Dissocn. consts., detd. by the gas-chain method: III 1.51×10^{-4}; I 3.83×10^{-4}; freshly crystd. $PhCH:CHCO_2H$ 3.98×10^{-5}. The addn. expts. in almost every case were carried out by boiling the acid 4, 10 and 240 hrs. or letting the ester stand 10 days at room temp. with 4 mols. NH_2OH. Tables are given showing the amount of unchanged material and yield of hydroxamino acid, oxime, isoxazolone and amino acid with I, III, IV, $PhCH:CHCO_2H$, α-, β- *o*-, *m*- and *p*-methyl-, *o*-nitro-, α- and β-phenylcinnamic acid and *o*-$HO_2CC_6H_4CH:CHCO_2H$ and their Me or Et esters and the esters of $CH_2:CHCO_2H$, *o*-, *m*- and *p*-hydroxy-, *cis*- and *trans*-*o*-methoxy-, *m*- and *p*-methoxy- and *m*- and *p*-nitrocinnamic acid. $C_4H_3OCH(NH_2)CH_2CO_2H$, m. 206°. *Acetylfuran oxime*, m. 102°. *γ-α'-Furfurylisoxazolone*, decomps. 147°, sol. in alkalies, insol. in HCl. *β-Amino-β-α'-furfurylpropionyl chloride-HCl* is obtained in 86.7% yield from the acid in AcCl with PCl_5. *Anilide*, m. 92°, easily sol. in HCl, difficultly in NaOH. *α-Benzoylamino-β-amino-β-α'-furfurylpropionic acid*, m. 173.5°, easily sol. in NaOH and HCl. *γ-α'-Furfuryl-β-benzoylaminoisoxazolone*, decomps. 181.5°, becomes yellow in the air, easily sol. in NaOH or Na_2CO_3. *Methylated α-benzoylamino-p-hydroxylamino-β-α'-furfurylpropionic acid*, probably $C_4H_3OCH(NHOMe)CH(NHBz)CO_2H$, since it is sol. in NaOH and Na_2CO_3 and reduces Fehling soln. only after some time, m. 203°, easily sol. in AcOH and HCl. *ω-Benzoylamino-α-acetylfuran oxime*, m. 157°, easily sol. in NaOH, difficultly in HCl. *α-Benzoylamino-β-ureido-β-α'-furfurylpropionic acid* (0.8 g. from 1 g. of the amino acid with KCNO in boiling H_2O), m. 196°. C. A. R.

Condensations of benzilic and anisilic acids and xanthydrol with thiophene and thionaphthene. J. Ancizar-Sordo and A. Bistrzycki. *Helv. Chim. Acta* **14**, 141–53 (1931).—Diphenyl-2-thienylacetic acid (I), $Ph_2C(C_4H_3S)CO_2H$, obtained in 80% yield by dissolving 2.3 g. benzilic acid (II) and 1.7 g. thiophene (III) in 20 cc. AcOH and adding 20 cc. of an equal wt. mixt. of H_2SO_4 and AcOH and letting stand 2 days, adding cold water and crystg. the residue from MeOH, m. 217–8°, dissolves in concd. H_2SO_4 with brownish red color; a dil. NH_4OH soln. treated with $AgNO_3$ yields a white, light-sensitive Ag salt; 1.5 g. heated 2 hrs. in a sealed tube at 100° with 0.5 g. KOH, 10 cc. MeOH and 3.2 g. MeI yielded 85% I Me ester, m. 149–50°. Diphenyl-3,5(?)-dibromo-2-thienylacetic acid (IV), $Ph_2C(C_4HBr_2S)CO_2H$, obtained is almost quant. yield by heating 1.5 g. I in 25 cc. AcOH after adding 1.6 g. Br, m. 213–4° (decompn. and green coloring). Diphenyl-2-thienylcarbinol (V), obtained in 30% yield by heating 1 g. I to 35° with 10 cc. of a mixt. of 10 vols. abs. H_2SO_4 and 2 vols. AcOH, pouring into water, yellow crystals from petr. ether, m. 129–30°. CO splitting from I as usual with H_2SO_4 (cf. Bistrzycki and Siemiradzki, *C. A.* **2**, 2379) gives even poorer yields. The yellow color of V is unexpected (cf. Thomas, *C. A.* **4**, 191). A.-S. and B. think it more likely that 4-valent S according to the following isomerism scheme explains the color of the solid V. $Ph_2(HO)CC:CH.CH:CH.S \rightleftharpoons Ph_2C:C.CH:CH.CH:SOH.$

Diphenyl-2-thienylmethane (VI), obtained in 85% yield by heating 1 g. I with 1.5 g. KOH and 7 cc. water in a tube at 180°, m. 63–4° dissolves in concd. H_2SO_4 with pale greenish-yellow color remarkably different from Ph_3CH. The structure of VI, previously in question from Levi's work (cf. *Ber.* **19**, 1623; also Minnis, *C. A.* **24**, 850), is settled by the above method of prepn. Levi failed to obtain HO, nitro or amino derivs. of VI and A.-S. and B. failed to prep. a HO deriv. by condensing II with III (later planning to split out CO). A reaction occurred but no product was isolated. 9-(2'-Thienyl)xanthene (VII), $O:(C_6H_4)_2CHC_4H_3S$, obtained in 75% yield by warming to 35° a mixt. of 2 g. xanthydrol (VIII) with 1.7 g. III after adding 3 g. P_2O_5 and a few cc. ether and then letting stand for 2 days, pale yellow, m. 150–1°, dissolves in concd H_2SO_4 with yellow color and intense green fluorescence. Diphenyl-2(?)-thionaphthylacetic acid (IX), $Ph_2C(C_8H_5S)CO_2H$, obtained in 95% yield by letting stand 3 days 2.3 g. II and 1.7 g. thionaphthene (X) in 20 cc. AcOH to which 20 cc. of an equal wt. mixt. of H_2SO_4 and AcOH was added, m. 244–5° (gas evolution and darkening); Na salt, difficultly sol. in water; 1.7 g. heated with 0.5 g. KOH, 10 cc. MeOH, and 3.2 g. MeI for 2 hrs. at 100° gave the Me ester of IX in 85% yield, m. 151–2°. Diphenyl-2(?)-thionaphthylcarbinol (XI), $Ph_2C(OH)C_8H_5S$, obtained in 35–40% yield by treating

1 g. IX with 8 cc. concd. H_2SO_4 and 2 cc. AcOH, m. 125–6°. The lack of color is unexpected if the suggested formula is correct (cf. Weissgerber and Kruber, *C. A.* **15**, 88, who point out that the Na compd. of X is not yet explained). Diphenyl-2(?)-thionaphthylmethane (XII), $Ph_2CHC_8H_5S$, obtained in 90% yield by splitting out CO_2 from IX as VI was obtained from I, m. 104–5°, dissolves in concd. H_2SO_4 with intense greenish orange color. Diphenyl-3(?)-bromothionaphthylacetic acid (XIII), $Ph_2C(C_8H_4BrS)CO_2H$, obtained in almost quant. yield by treating 1.7 g. IX with 1.6 g. Br, m. 223–4° (decompn.); dissolves in concd. H_2SO_4 with violet-red color. Diphenyl-3(?)-bromothionaphthylcarbinol (XIV), $Ph_2C(OH)C_8H_4BrS$, obtained in 75% yield by the method of prepg. XII from IX, m. 166–7°, dissolves in concd. H_2SO_4 with violet-red color. 4,4'-Dimethoxydiphenyl-(?)-thionaphthylacetic acid (XV), $(MeOC_6H_4)_2C(C_8H_5S)CO_2H$, obtained in 90% yield by treating a soln. of 2.9 g. of anisilic acid and 1.7 g. X in 20 cc. AcOH with 20 cc. of a mixt. of equal wts. H_2SO_4 and AcOH, letting stand 2 days, m. 245–6° (decompn.); the Ba salt is almost insol. in water; Me ester, in 90% yield prepd. as the Me ester of IX, m. 166–7°. CO evolution resulted when XV was treated with H_2SO_4 or H_2SO_4 and AcOH but no product was isolated. 9-(2(?)Thionaphthyl)xanthene, $O:(C_6H_4)_2CHC_8H_5S$, obtained in 50% yield by refluxing 2 hrs. 2 g. VIII, 1.7 g. X, 3 g. P_2O_5 and 5 cc. ether, and letting stand 2 days, m. 172–3°, dissolves in H_2SO_4 with yellow color and intense blue-green fluorescence. O. E. S.



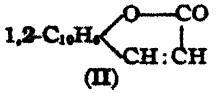
New methods of formation of coumarone and of diphenylene oxide. N. A. Orlov and V. V. Tishchenko. *Ber.* **63B**, 2948–51(1930); cf. *C. A.* **24**, 110.—Coumarin (350 g.), passed at the rate of 50 g. per hr. through a 2 cm. tinned Fe tube, 60 c. long, at 860° gave a gas consisting of 4.0% CO_2, 71.6% CO, 19.2% H and 4.8% C_nH_{2n}, and 297 g. of a thick brown product sepd. by distn. into 56 g. b. 80–200° (I), 16 g. b. 200–88°, 75 g. b. 288–305° and 146 g. residue. The 3rd fraction and a considerable portion of the 2nd fraction consisted of unchanged coumarin and the residue, which was very similar in all its properties to coumarone resin, gave on dry distn. 78.6 g. oil (II), which was combined with I, and 56 g. of a porous coke. The combined I and II, freed of acid products (phenols) with NaOH, was sepd. by careful fractionation into 8 g. b. 80–172° (chiefly C_6H_6 hydrocarbons), 122 g. practically pure coumarone, b. 172–4°, and 8 g. residue (mainly coumarin). Under pressures greater than atm. the decompn. of coumarin follows another course; heated 4 hrs. at 420° in an autoclave the coumarin gave only gases and coke. Coumarin may be considered as an α-benzopyrone, and xanthone (dibenzo-γ-pyrone) (100 g.), treated like the coumarin at 880°, gave a gas consisting of 94% CO, 1.76% CH_4 and 2.1% H, and a black cryst. mass giving on distn. 15 g. of a product b. 285–300° which, through the picrate, gave 9.5 g. diphenylene oxide, m. 85°. Dimethylpyrone was similarly treated, but because of lack of material the best conditions for a smooth degradation into CO and dimethylfuran could not be worked out. The formation of a volatile compd. with pronounced furan properties and the evolution of large quantities of gas rich in CO was observed, however C. A. R.

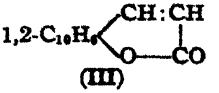
The hydrolysis of acetylindoxylic acid and the acetylindoxyls. Geoffrey Spencer. *J. Soc. Chem. Ind.* **50**, 63–4T(1931).—*N-Acetylindoxylic acid*, AcN.C_8H_4.$CO.CHCO_2H$ (I). A melt of 10 g. of *o*-$HO_2CC_6H_4NHCH_2CO_2H$ and 45 g. of 80% KOH, fused at 260° for 10 min., was ground up, mixed with 50 g. of ice and partly neutralized with 35 cc. of AcOH at 0° in a CO_2 atm. Ten cc. of Ac_2O was added and after 30 min. the ppt. of *O*-acetylindoxyl was filtered off. Acidification of the filtrate with HCl gave I, m. 179° (decompn.). I was also obtained by acetylating acid indoxylic acid solns. Hydrolysis of I was expected to give indoxylic acid, indoxyl and then indigo but on the contrary a marked tendency to ring cleavage was shown. Hydrolysis with Na_2CO_3, alk. H_2O_2 and NaOH gave 50% of $NH_2C_6H_4CO_2H$ and some indigo, whereas treatment with HCl or acid $FeCl_3$ yielded $NH_2C_6H_4CO_2H$ solely. *N-Acetylindoxyl* (II) was prepd. by the method of Vorländer and Pfeiffer (*C. A.* **13**, 2356), after attempts to decarboxylate indoxylic acid by boiling had failed. On boiling II in the presence of air with dil. Na_2CO_3, indigo, diacetylindigo and isatin were obtained in 55, 8 and 12% yields, resp. Dil. NaOH gave mainly indigo (74%) together with isatin, while acid $FeCl_3$ gave only isatin. *O-Acetylindoxyl* (III). An indoxylic acid melt was partly neutralized, boiled for 10 min., cooled, and acetylated with Ac_2O. After standing for 30 min., III was filtered off, washed free from acetylindoxylic acid and crystd. from H_2O. After drying *in vacuo*, 15% yield of III, m. 127.5°, was obtained. Hydrolysis with Na_2CO_3 yielded 95% indigo and 3–4% isatin; treatment with alk. H_2O_2 gave mainly isatin, 18% indigo and some $NH_2C_6H_4CO_2H$. Acid $FeCl_3$ gave indirubin (18%) and isatin. C. R. Addinall

3,5-Diketopyrazolidine derivatives. I. TOKUICHI TSUMAKI. *Bull. Chem. Soc. Japan* **6**, 1–9(1931).—*1,2-Diphenyl-3,5-diketopyrazolidine* (I). $(PhNH)_2$ (18.5 g.) in 300 cc. of Et_2O was added from a dropping funnel to a soln. of 10 g. of $CH_2(COCl)_2$. The white ppt., washed with Et_2O in the absence of moist air, was extd. with petroleum ether and recrystd. from EtOH; yield 6 g., m. 178°. The ether filtrate was washed with water and shaken with 1% Na_2CO_3. On acidification with HCl the alk. soln. gave a ppt. which when dissolved in $CHCl_3$ and treated with EtOH yielded crystals of *1,2-diphenyl-3,4-dihydroxy-5-pyrazolidone* (II), m. 160–2°. This compd. was also obtained by dissolving I in a mixt. of $CHCl_3$ and EtOH, and allowing the soln., acidified with a trace of HCl, to stand for a few days. I and II were obtained by the action of C_4O_2 on $(PhNH)_2$, the poor yields being accounted for by polymerization of the main part of the C_4O_2 during the reaction. I forms an NH_4 salt, m. 138–9°, and an isonitroso deriv., m. 163–4°. It condenses readily with aldehydes and ketones, giving products easily decompd. by hot alkali. From BzH, O.CH:CH.CH:CCHO, PhCH:CHCHO, Me_2CO, MeBz and PhBz the following 1,2-diphenyl-3,5-diketopyrazolidine derivs. were formed: 4-benzylidene, m. 164–5°; 4-furfurylidene, m. 157–8°; 4-cinnamylidene, m. 190–2°; 4-isopropylidene, m. 113°; 4-(α-phenylethylidene), m. 148–9°, and 4-(diphenylmethylene), m. 269°. C. R. ADDINALL

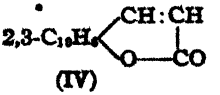
Equilibrium and "intermediate stage." F. ARNDT. *Ber.* **63B**, 2963–6(1930).—In agreement with v. Auwers *et al.*, who, in their work on the *N*-alkyl-γ-pyridones (*C. A.* **25**, 295), misunderstood the attempted explanation, in footnote 2 to the paper by A. and Kalischek (*C. A.* **24**, 3239), on an electronic theoretical basis, of A.'s conception of the difference between equil. and "intermediate stage," A. explains more fully this conception, which is dealt with in detail by his pupil Lorenz (*Diss. Breslau*, **1927**) but is referred to only incidentally here and there in A.'s own papers. C. A. R.

Reactivity of conjugated systems. II. Condensation of acetylenic ketones with cyanoacetamide. CHITTARANJAN BARAT. *J. Indian Chem. Soc.* **7**, 851–62(1930); cf. *C. A.* **24**, 4785.—PhCOC : CPh and $CNCH_2CONH_2$ condensed according to Michael's method to *3-cyano-4,6-diphenyl-2-pyridone* (I), m. 320°, in 60% yield. I is identical with the dehydrogenated product from PhCOCH:CHPh and $CNCH_2CONH_2$. The Na salt of I is sparingly sol. in water; on much diln. the soln. becomes turbid from hydrolysis. With Knoevenagel's reagent 40–50% of an identical compd. was obtained on 1 week's standing. The structure is





(II) (III)



of which III predominates in the presence of alkali. The *N*-Me deriv. (IV), m. 175°, is identical with that from condensation with $CNCH_2CONHMe$. Diln. of the H_2SO_4 soln. of I gives 4,6-diphenyl-2-hydroxypyridine (V). I and II give no color with alc. $FeCl_3$ but V does. V does not yield a Me deriv. readily and is probably PhC:CH.CR:N.C(OH):CH. V could also be reached from I by an intermediate compd. $PhC(CH_2COR):C(CN)CONH_2$. The stability of the condensation products increases with increasing neg. character of R. An extension of Fry's substitution rule is offered in explanation. *p-Tolylphenylacetylene*, b_{15} 200–10°, m. 72°, and $CNCH_2CONH_2$ gave *3-cyano-4-phenyl-6-p-tolyl-2-pyridone* (VI), m. 268°. VI was also obtained from *p*-MeC_6H_4COCH:CHPh and from α-methoxy-ω-*p*-tolylstyrene; *N-Me* deriv., m. 136–8°. *4-Phenyl-6-p-tolyl-2-hydroxypyridine*, m. 228°. *Et 4-phenyl-6-p-tolyl-2-pyrone-3-carboxylate*, m. 85°. *4-Phenyl-6-p-tolyl-2-pyrone*, m. 133°. *p-*NO_2*-*C_6H_4COC : *CPh*, m. 161–2°. *3-Cyano-4-phenyl-6-p-nitrophenyl-2-pyridone*, m. 332–3°; *N-Me* deriv., m. 322–4°. *4-Phenyl-6-p-nitrophenyl-2-hydroxypyridine*, m. 275–6°. *Et 4-phenyl-6-p-nitrophenyl-2-pyrone-3-carboxylate*, m. 148°. *4-Phenyl-6-p-nitrophenyl-2-pyrone*, m. 235°. *3-Cyano-4-phenyl-6-methyl-2-pyridone*, m. 275–6°; *N-Me* deriv., m. 146°. *4-Phenyl-6-methyl-2-hydroxypyridine*, m. 206–8°. *Et 4-phenyl-6-methyl-2-pyrone-3-carboxylate*, m. 92°. *4-Phenyl-6-methyl-2-pyrone*, m. 185–6°. *3-Cyano-4-phenyl-6-ethyl-2-pyridone*, m. 267–8°; *N-Me* deriv., m. 158°. *4-Phenyl-6-ethyl-2-hydroxypyridine*, m. 165°. FOSTER DEE SNELL

The third *o*-hydroxynaphthaldehyde and the isomeric β-naphthocoumarins. THEODOR BOEHM AND ELMAR PROFFT. *Arch. Pharm.* **269**, 25–37(1931).—Of the 3 possible *o*-hydroxynaphthaldehydes only 2 were known, to which the structures 1,2- and 2,1-$C_{10}H_6(OH)CHO$ were ascribed. The prepn. of the 2,3-isomer (I) was un-

successfully attempted some years ago by Zetzsche and co-workers by the catalytic reduction of $C_{10}H_6(OH)COCl$. These expts. were taken up anew by B. and P. who, following the procedure of Rosenmund and starting with 2,3-$C_{10}H_6(OH)CO_2H$ succeeded in prepg. I, by the following transformations: $C_{10}H_6(OH)CO_2H \longrightarrow C_{10}H_6(OAc)CO_2H \longrightarrow C_{10}H_6(OAc)COCl \longrightarrow C_{10}H_6(OAc)CHO \longrightarrow$ I. This synthesis clarifies the questions hitherto existing in the constitutional make-up of the isomeric β-naphthocoumarins (III and IV).

(II)

(III)

(IV)

Owing to its derivation from α-naphthol no question arises respecting the structure of α-naphthocoumarin (II). Of the isomeric β-naphthocoumarins, the one prepd. by Kauffmann from β-naphtholaldehyde according to Perkin, m. 118°, is represented by (III). A 2nd β-naphthocoumarin was described by v. Pechmann and Welsh (*cf. Ber.* 17, 1646); it m. 141° and was designated as iso-β-naphthocoumarin. Its constitution was left undetd.; from K.'s work only structure IV would remain for it. However, when β-naphtholaldehyde was subjected to the Perkin synthesis, a product m. 163°, resulted, entirely unlike Pechmann's "iso-β-naphthocoumarin," and undoubtedly having the structure IV. Repetition of the v. Pechmann expts. on condensation of β-naphthol with malic acid in the presence of H_2SO_4 yielded a product m. 118° and identical with K.'s β-naphthocoumarin. If the same reaction is applied to α-naphthol—which according to Pechmann does not react at all—a product, m. 141°, results (already observed by Bartsch, *Ber.* 36, 1966); it is II, which had been previously prepd. by another procedure by Bezdzik and Friedländer (cf. *Monatsh. Chem.* 30, 280). Accordingly, the assumption is safe that v. Pechmann and Welsh had in hand II and that an "iso-β-naphthocoumarin," m. 141°, has no existence in fact and should be deleted from the literature. During the present study, the following compds. were prepd. and characterized: 2,3-$C_{10}H_6(OH)COCl$, m. 100° (Graff, *Ann.* 367, 253, reports m. p. 89°), which gave on reduction *2-acetoxynaphthoic aldehyde*, $C_{13}H_{10}O_4$, bright yellow, m. 100–1°, likewise the related by-product *acetoxynaphthoic anhydride*, $C_{26}H_{18}O_7$, m. 156°. I, $C_{11}H_8O_3$, yellow plates from dil. AcOH, m. 99–100°; *phenylhydrazone*, $C_{17}H_{14}ON_2$, yellow, m. 246–8°; *p-nitrophenylhydrazone*, $C_{17}H_{13}O_3N_3$, brownish yellow, m. 271–3°; *semicarbazone*, $C_{12}H_{11}O_3N_3$, m. 270°; *oxime*, $C_{11}H_9O_3N$, m. 207°; *anil*, $C_{17}H_{13}ON$, golden, m. 158–9° (*p-nitrophenylhydrazone*, $C_{16}H_{13}O_4N_3$, golden, m. 213–4°; *semicarbazone*, $C_{14}H_{13}O_3N_3$, m. 211–2°; *oxime*, $C_{13}H_{11}O_3N$, m. 202–3°). *β-Hydroxy-β-naphthylideneacetone*, $C_{14}H_{12}O_2$, yellow, m. 207–8°. *β-Hydroxy-β-naphthylideneacetophenone*, $C_{19}H_{14}O_2$, yellow, m. 188–9°. *β-Hydroxy-β-naphthylideneacetylacetone*, $C_{18}H_{14}O_3$, bright yellow, m. 162–3°. *β-Hydroxy-β-naphthylideneoxalacetic ester*, $C_{15}H_{12}O_5$, yellow, m. 112–3° (*Ac deriv.*, $C_{21}H_{20}O_7$, m. 142–3°). Condensation of I with Ac_2O and AcONa yielded IV, yellowish white, m. 163–4°. Alc. $PhNH_2$ or NH_3 effects condensation of I with malonic acid to yield *iso-β-naphthocoumarincarboxylic acid*, $C_{14}H_8O_4$, yellow, m. 258–9° (*Et ester*, $C_{16}H_{12}O_4$, yellow, m. 157–8°). With $AcCH_2CO_2Et$ and piperidine I yields *3-acetyl(iso-β-naphthocoumarin)*, $C_{15}H_{10}O_3$, yellow, m. 209–10° (*p-nitrophenylhydrazone*, $C_{21}H_{15}O_4N_3$, yellow, m. 266–7°; *Bz deriv.*, $C_{22}H_{12}O_3$, yellow, m. 225°). *Et (3-cyano-3,4-dihydro-iso-β-naphthocoumarin)cyanoacetate*, from the condensation of I with $NCCH_2CO_2Et$ in the presence of piperidine, m. 158–9°.

(II)

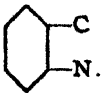
XXI. The reaction between sinomenine and formaldehyde. Kakuji Goto, Hideo Shishido and Reikichi Inaba. *Ibid* 315–20.—The interaction of sinomenine and 40% HCHO gives *5-hydroxymethylsinomenine* (I) and *1,5-dihydroxymethylsinomenine* (II). I m. 260° (decompn.), $[\alpha]_D$ −40.71°; oxime, m. 240–5°; methiodide, m. 223°, gives a green $FeCl_3$ reaction, a faint ferricyanide reaction, an intensely red diazo reaction and a green-brown HCHO-H_2SO_4 reaction. II m. 242° (from alc.) or 252° (from $CHCl_3$), $[\alpha]_D$ −74.39°; oxime m. 200-15°; methiodide m. 210°, decomps. 280°, gives a brown $FeCl_3$ reaction, a red diazo reaction, no ferricyanide reaction and a green HCHO-H_2SO_4 reaction. The reduction of V gives *dihydro-5-hydroxymethylsinomenine*, m. 244°, $[\alpha]_D$ 73.03°; oxime, m. 215–25° (decompn.), gives a green $FeCl_3$ reaction, an intensely red diazo reaction, a faint ferricyanide reaction and a blue-violet HCHO-H_2SO_4 reaction.

Albert L. Henne

Constitution of matrine. XIII. Action of Grignard reagent on matrine (1). H. Kondo, E. Ochiai and K. Iwava. *J. Pharm. Soc. Japan* **51**, 1–8(1931), German abstr. 1–3; cf. *C. A.* **23**, 2447.—*Matrine* (18.5 g.), when treated with MeMgI, followed by decompn. with NH_4Cl, gave a compd. (I), m. 221–30°, with mol. formula of $C_{16}H_{28}N_2O.HI.H_2O$ or $C_{16}H_{30}N_2O.HI.H_2O$. On hydrolysis I gave bases (II), b_6 165° and

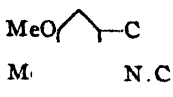
(III), b_6 236–40°. II, m. 65°, d_4^{20} 1.0342, $n_D^{25.5}$ 1.531886; *picrate* decomps. 268°; styphnate decomps. 306°. II cannot be reduced with a catalyst, but gives pos. diazo and Liebermann reactions. II can be neither benzoylated nor acetylated. III, $C_{16}H_{26}N_2O$ or $C_{16}H_{28}N_2O$, gives pos. diazo and Lieberman reactions, but the reaction for the C:O group is neg. The reaction is shown in the following equation:

F. I. NAKAMURA



Mechanism of the oxidation of laudanosine. VINAYAK K. BHAGWAT, DOUGLAS K. MOORE AND FRANK L. PYMAN. *J. Chem. Soc.* **1931**, 443.—The compd., $C_{14}H_8(OMe)_4$, m. 231°, obtained by Pyman in the oxidation of laudanosine by MnO_2 in H_2SO_4 (*C. A.* **3**, 2966), is 2,3,6,7-tetramethoxy-9,10-dihydroanthracene (Robinson, *C. A.* **9**, 1602), it seps. from Me_2CO with 0.5 H_2O and from C_6H_6 with 0.5 C_6H_6. This identification counteracts the view of Gadamer (*C. A.* **10**, 1033) of the mechanism of this oxidation.

C. J. WEST



Oxonitine and remarks on a paper of S. Akabori and K. Saito. ERNST SPÄTH AND FRIEDRICH GALINOVSKY. *Ber.* **63B**, 2994–7(1930).—Earlier workers have assigned to oxonitine a formula with 23–25 C atoms, with 3 MeO groups, and it therefore seemed that if the 3 MeO, the Ac and the Bz groups were split off there would remain a compd. with only 11–13 C atoms whose structure, it was hoped, might be established and prove of great importance for the elucidation of the chemistry of the aconitines. It was soon found, however, that the formulas of the earlier investigators are incorrect, as oxonitine contains only 2.21% N instead of the 3.04–2.76% required by these formulas, and 4 instead of 3 MeO groups. Especially convincing evidence of the incorrectness of these formulas was afforded by a careful detn. of the Bz content by sapong. the oxonitine with alc. KOH, extg. the BzOH with Et_2O, subliming it at 130–50° under 10 mm and weighing the sublimate (a control detn. on aconitine gave 16.09–16.16% Bz; calcd. 16.27). In this way oxonitine was found to contain 16.08–16.28% Bz instead of the 4.1–6.1% calcd. for the older formulas. Numerous analyses gave an av. C and H content of 60.48 and 6.90%. The formula for oxonitine is therefore $C_{32}H_{43}O_{12}N$ (the true H content may differ from this by 2 atoms) and the hope of obtaining a relatively simple product by its hydrolysis proved to be illusory. Akabori and Saito (*C. A.* 25, 700), in referring to a paper by Späth and Lederer, convey the erroneous impression that S. and L. considered their β-(6-methoxy-β′-indolyl)ethylamine, m. 112–30°, to be the pure base; it was obtained by a ring closure proceeding in 2 directions, which would naturally give impure end products, and S. and L. made no attempt to sep. the resulting mixt. of free bases but isolated them as their *N*-Ac derivs. C. A. R.

Constitution of the strychnos, yohimbe and quebracho alkaloids. ERNST SPÄTH AND HERMANN BRETSCHNEIDER. *Ber.* **63B**, 2997–3006(1930).—Oxidation of strychnine with alk. $KMnO_4$ on the H_2O bath until the consumption of the $KMnO_4$ slowed up gave a mixt. of acids sepd. by their different acidities; one fraction gave an Et_2O-sol. acid (I) whose purification was rendered difficult by the fact that H_2O, the best solvent for it, gradually decomps. it at high temps. It was accordingly treated with CH_2N_2 which gave a pure di-Me deriv. $C_{11}H_{11}O_4N$ (II) which regenerated I with alc. KOH. Thermal decompn. of the K salt of I gave *o*-$H_2NC_6H_4CO_2H$ and I was identified as *o*-$HO_2CCONHC_6H_4CO_2H$ and II as its *di-Me ester* by synthesis. A sample of the acid, m. 195°, obtained by Warnat by oxidation of yohimboaic acid and to which he assigned the compn. $C_9H_7O_4N$, also proved to be identical with I. Intending to oxidize yohimboaic acid themselves, S. and B. used for its prepn. a sample of com. yohimbin hydrochloricum and found that the decompn. products and rotation of this base and the acid obtained from it by sapon. agreed almost completely with Hahn's data on quebrachine, and oxidation of the acid obtained from the quebrachine-HCl yielded I. These results show that strychnine and the yohimbe and quebracho alkaloids contain the grouping III; whether the N is present in a quinoline or an indole ring cannot as yet be stated. Brucine uses up $KMnO_4$ more rapidly than strychnine and the yield of resulting acid is smaller; this was identified by synthesis as *4,5-dimethoxy-N-oxalylanthranilic acid* (IV), showing that brucine contains the grouping V, as assumed by Leuchs and by

Perkin and Robinson. I, prepd. by Kretschy's method, decomps. 229–30° (the m. ps. 180–210°, recorded in the literature, are probably due to the presence of impurities acting catalytically). II, m. 152.5°. The *di-Me ester*, m. 205–6°, of IV was synthesized by fusing 2,4,5-$H_2N(MeO)_2C_6H_2CO_2Me$ with anhyd. $(CO_2H)_2$ and methylating the resulting *mono-Me ester*, decomps. 230° to a turbid liquid which clears up at 232°, with CH_2N_2.

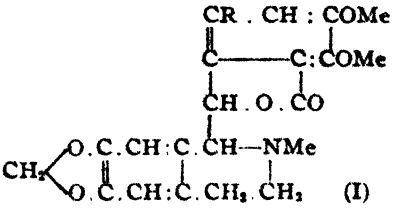
(V)

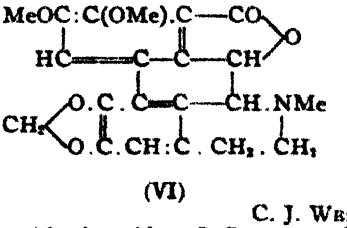
C. A. R.

The melting point of pure yohimbine (remarks on the communication of G. Hahn and W. Schuch). K. Warnat. *Ber.* **63B**, 2959–61(1930); cf. H. and S., *C. A.* **24**, 5039.—H. and S. claim that *pure* yohimbine, obtained by fractional crystn. of a com. product contg. as chief impurity the so-called α-yohimbine, m. 215–6° instead of 230–5°, as generally accepted. W., in earlier work on the sepn. of these 2 alkaloids, had found that this is by no means easily effected by fractional crystn., for his isoyohimbine is none other than H. and S.'s α-yohimbine, and this isoyohimbine easily depresses the m. p. of yohimbine to 212–8°. A few new expts. with pure yohimbine have confirmed the old m. p., 234°, of the base, which showed $[\alpha]^{20}_D$ 98.8° (C_5H_5N, *c* 0.921); HCl salt, m. 302°, $[\alpha]^{22}_D$ 103.3°. Yohimboaic acid, m. 259°; anhydride, m. 298°. The rotation of 70–95° given by H. and S. for yohimbine·HCl and the decompn. temp. 284° for the yohimboaic acid also point to contamination with isoyohimbine. C. A. R.



Identity of α-yohimbine with isoyohimbine. G. Hahn and W. Schuch. *Ber.* **63B**, 2961–2(1930); cf. *C. A.* **24**, 5039.—Whether or not Warnat's isoyohimbine (see preceding abstr.), which he did not sharply characterize, is identical with α-yohimbine, there is no doubt that the alkaloid decompg. 239–40°, which H. and Brandenburg called isoyohimbine (*C. A.* **21**, 1815) is different from α-yohimbine. C. A. R.

Properties of nicotine and its derivatives. III. Chloronicotine and methylnicotine. Thomas M. Lowry and Hamid Khan Gore. *J. Chem. Soc.* **1931**, 319–23; cf. *C. A.* **23**, 5186.—Chloronicotine (I) in EtOH shows an absorption band with max. log ε = 3.55 at 2700 A. U., as compared with log ε = 3.37 at 2600 for nicotine. Methylnicotine (II) gives a max. log ε = 3.44 at 3100 A. U. in cyclohexane and 3.66 at 2950 in H_2O. The rotatory dispersion of *l*-I can be expressed by 1 term of Drude's equation with characteristic wave length λ_0 = 2550 A. U. II gives λ_0 = 2668 A. U. in cyclohexane and 2654 in H_2O. Both compds., therefore, behave like the parent base and not like its salts, which are *d*-rotatory and of much lower dispersion. C. J. West



Santoninic acid amide. Karl Josephson. *Svensk Farm. Tids.* **35**, 69–75(1931); cf. *C. A.* **25**, 1534.—Five g. santonin in 50 cc. abs. alc. was satd. with dry NH_3 and shaken for over 1 day and then set aside for 2 days in a dark place. The NH_3 was removed by evapn. at reduced pressure. Yellowish red crystals formed but the color was completely removed by acetone. The yield is quant. The product m. 177°, $[\alpha]^{22}_{Hg}$ −18.1°, it is more sol. in water than santonin and is not very sol. in org. solvents; of these alc. is best. On heating it reverts to santonin. A. R. Rose

Synthesis of hydrastine. I. Edward Hope, Frank L. Pyman, Frederick G. P. Remfry and Robert Robinson. *J. Chem. Soc.* **1931**, 236–47; cf. *C. A.* **7**, 2927.—Condensation of hydrastinine and nitromeconin in boiling EtOH gives 80–90% of a mixt. of *anhydrohydrastininenitromeconins* (I, R = NH_2); it is orange-yellow; two samples m. 167–8° and 173°; *HCl salt*, yellow, m. 137–8°; sepn. by means of the HCl salt was not successful. Reduction with Sn or $SnCl_2$ in HCl and AcOH gives a mixt. of aminohydrastines *a*(II) and *b*(III), which were sepd. by the difference in soly. of the HCl salts and also of the bases. II, m. 216–7° (cor.), sparingly sol. in EtOH and Et_2O, in which it exhibits an intense blue fluorescence; *HCl salt*, m. 267–8°; *tartrate*, m. 201–3° (cor.); *Ac deriv.*, m. 208–11°. III, m. 196–7° (cor.); cryst. salts could not be obtained. Reduction of the diazo compd. from II gives *hydrazinohydrastine-a*(IV), m. 175° (cor.); *acid oxalate*, m. 225° (decompn.); *isopropylidene deriv.*, m. 190°. The *b-isomer* (V), crystals with 1 mol. $CHCl_3$, m. 183–4°; *isopropylidene deriv.*, m. 217–8°. Oxidation of IV with $Cu(OAc)_2$ gives *hydrastine a*, m. 137–8° (cor.); HCl salt, decomps. above 165°; acid oxalate, sparingly sol. in cold H_2O; *picrate*, bright yellow, m. 219° (decompn.) (the *picrate* of *l-hydrastine*, bright yellow, m. 184°); *H d-tartrate*, crystals with 3.5 mols. H_2O, m. 108–10° (cor., decompn.); *d-camphorsulfonate*, crystals with 0.5 mol. H_2O, m. 145° (cor., decompn.). V gives only a small quantity of *hydrastine-b*,

m. 150–1° (cor.); tartrate, m. 65–70°; the main product of the reaction is *dadihydrohydrastine* (VI), m. 183°; the H_2SO_4 soln. changes from colorless to yellow, orange, reddish brown, greenish brown, slaty blue and violet on heating. A comparison is given of the behavior of *l*-hydrastine, hydrastine-*a* and -*b* and VI on oxidation in H_2SO_4 with MnO_2. IV and $CuCl_2$ in about 0.5% HCl give *chlorohydrastine-a*, m. 152°, reduced by Al-Hg to hydrastine-*a* (poor yield); the I *deriv.* (VII) m. 172° and gives a better yield of hydrastine-*a* on reduction. Condensation of hydrastinine and iodomeconin gives as the main product VII but some of the *b-isomer*, m. 193–5°, is also formed; the *HCl salts* of the 2 isomers m. 222–3° (cor., decompn.). Bromomeconin gives a *bromohydrastine*, m. 170–1° (cor.); *HBr salt*, m. 287–8° (decompn.). Normeconin Me ether with Ac_2O and AcONa gives 90% of *4-acetoxy-3-methoxyphthalide*, m. 127–8° (cor.); *4-benzoyloxy deriv.*, m. 135–6° (cor.); *m-nitrobenzoyloxy deriv.*, m. 192–3° (cor.); *p-isomer*, m. 202–3°. These acyl derivs. did not condense with hydrastinine under any conditions tried. The Me ether itself gives a *hydrastininium salt*(?), m. 334° (cor.), gives no color with $FeCl_3$ but on warming with dil. acid or alkali, the blue color of the Me ether could be obtained.

C. J. West

Salicinerein of Salix cinerea L.; its identity with piceoside. J. Rabate. *Bull soc. chim. biol.* **12**, 965–73(1930); cf. *C. A.* **24**, 4517, 4788.—The 2 compds. are identical (β-glucoside of *p*-hydroxyacetophenone). C. G. King

Saponin of Panax repens, Maxim. V. Panaxsapogenin. S. Aoyama. *J. Pharm Soc. Japan* **50**, 1163–74(1930): German abstr. 153–7; *C. A.* **25**, 1533.—In the previous paper A. proposed the structure $-CHMeCH(OH)^{II}CH(CHMe_2)C.C.C.CCH(CO_2H)$ OH^{I} for *panaxsapogenin* (I) and showed that OH^{I} can be acetylated while OH^{II} cannot and that the positions of the unsatd bonds are as shown above. I (50 g.) when treated with an equal wt. of Se at 330–60° for 70 hrs gave a compd. (II) m. 299–300° which reduced the m. p. of I to 277°. II was fractionated into (*A*) b_{12} 70–100° (0.25 g.), (*B*) b_{12} 100–50° (6.28 g.), (*C*) b_{12} 150–70° (4.45 g.). (*B*) was distd. further over Na which gave (B_1) b_{12} 125° (0.52 g.), (B_2) b_{12} 125–45° (2.45 g.) and (B_3) b_{12} 145–50° (1.28 g.). The *picrate* of (B_2) m. 123.7° and corresponds to *sapotalin picrate*, $C_{31}H_{41}N_3O_7$. On distg. over Na (*C*) gave (C_1) b_{10} 147–9° (0.37 g.) and (C_2) b_{10} 149–56° (2.05 g.). *Picrate* of (C_2) m. 125–30° and corresponds to *tetramethylnaphthalene picrate* $C_{28}H_{31}N_3O_7$. I (5 g.) when treated with 50% HCO_2H (d. 1.215) for 2 hrs gave a compd. $C_{28(30)}H_{36(40)}O_3$ (III), m. 243 3.5°, $[\alpha]_D^{29}$ 67.54°. III is called *repenin*. *Me ester* of III m. 161–4°, $[\alpha]_D^{8}$ 93.22°, *phenylurethan* m. 230°. III cannot be acetylated. Fusion of III with alkali, followed by careful acidification, gave *isorepenin*, m. 293–4°, probably a lactone. The formation of a lactone from I may be due to the formation of an α-hydroxy-γ-lactone, followed by dehydration. F. I. Nakamura

Acid- and alkali-binding power of peptides. R. Stiasny and H. Scotti. *Ber.* 63B, 2977–83(1930).—The object of this work was to det., by a study of the titration curve of glycine and its mono-, di-, tri-, tetra- and pentaglycyl derivs. (which contain only 1 NH_2 and 1 CO_2H group but an increasing no. of peptide unions), whether the peptid unions play a part in the acid- and alkali-binding power of peptides. The titration curve of glycine anhydride (diketopiperazine) was also detd. The curves show that glycine behaves like a weak monoacid base and a weak monobasic acid. Addn. of HCl at first greatly diminishes the p_H value of its soln. and then slowly decreases the p_H value of the resulting buffer. After the addn. of 1 equiv. HCl the curve coincides with that of HCl itself. Addn. of NaOH increases the p_H value in an analogous way. The dipeptide behaves exactly like glycine with HCl but with NaOH the curve does not show an inflection as soon as 1 equiv. NaOH has been added and further addn. of NaOH gives lower p_H values than would be obtained if the curve coincided with that for pure NaOH. The same behavior toward HCl and NaOH is shown by the higher peptides except that the greater the no. of peptide unions present the further away from the

point corresponding to 1 equiv. NaOH is the point of inflection of the curve shifted, and the greater is the difference between the curve for the peptide and that for pure NaOH (the hexapeptide curve is not entirely comparable with those of the other peptides because a suspension had to be used). These results show that the peptide unions take part in the binding of alkali but not in that of acid. The curve for glycine anhydride indicates that there is no acid binding and only a very slight binding of alkali. The following dissocn. consts. ($K_a \times 10^9$ and $K_b \times 10^{11}$) and isoelec. points (p_H), resp., are calcd. for the peptides from the curves: di, 0.63, 1.35, 5.66; tri, 1.0, 1.26, 5.50; tetra, 1.78, 1.12, 5.40; penta, 2.0, 1.12, 5.38; hexa, 2.5, 1.12, 5.32. For glycine, the values are: $K_a \times 10^{10}$ 1.99, $K_b \times 10^{12}$ 2.6, p_H 6.06. C. A. R.

The bile acids. XXXIII. Bromination of dehydrocholic acid and of dehydrodesoxycholic acid. HEINRICH WIELAND AND TAKAMI NOGUCHI. *Z. physiol. Chem.* **194**, 248–59(1931); cf. *C. A.* **25**, 1535.—The 2 simplest keto acids of the bile acid series, *viz.*, dehydrocholic acid (I) and dehydrodesoxycholic acid (II), were brominated and the Br removed by hydrolysis, in order to obtain material for a study of oxidative breakdown. Contrary to expectation, the substitution of Br in all positions adjacent to CO is not easily accomplished. Ring I appears to be the most reactive, since bromination is much more difficult in the case of desoxybilianic acid where this ring has been opened by oxidation. *Bromodehydrocholic acid*, m. 182–3° (decompn.), was obtained from I and the calcd. quantity of 4 *M* Br in AcOH at 15°; *Et ester* m. 192° (decompn.). Treatment of the acid with cold 0.1 *N* KOH converted it to *hydroxydehydrocholic acid*, m. 187° (decompn.). Further bromination of I in the cold gave *α-dibromodehydrocholic acid* which contains solvent of crystn. not removable at 100° *in vacuo*. With 1 AcOH the m. p. is 200°, with 0.5 Et_2O it is 174° and with 1 EtOH the decompn. point is 206°. Treatment of the di-Br deriv. with 0.5 *N* KOH gave *dihydroxydehydrocholic acid*, 2 fractions m. 198° and 212–3°, resp., both contg. 1 Et_2O. A similar treatment with 0.315 *N* $Ba(OH)_2$, followed by acidification, and Et_2O extn. of the ppt. gave the unsatd. *hydroxytriketocholenic acid*, m. 257° (decompn.), crystg. with 0.5 AcOH. When I was brominated at higher temps. with excess Br_2 an isomeric *β-dibromodehydrocholic acid*, m. 265–6°, was obtained. It holds 1 AcOH tenaciously. This isomer probably results from a rearrangement due to a reversal of the reaction after the 1st Br is substituted. Treatment of I with 5 Br_2 at 30° gave a *tetrabromodehydrocholic acid*, m. 213°. The mother liquor contained a *tribromodehydrocholic acid*, decomps. 202–3°, which could not be freed from admixt. with the tetra deriv. Finally, a *pentabromodehydrocholic acid*, m. 192°, was obtained from I and 8 Br_2. An improved method is described for the prepn. of II, which consists essentially in dissolving I in a large vol. of AcOH, cooling the soln. to 10° and turbining with CrO_3 at this temp., then pptg. the product with water, dissolving in Na_2CO_3, repptg. with HCl and extg. with Et_2O. Bromination of II yielded *tribromodehydrodesoxycholic acid*, m. 212–3° (decompn.), contg. 0.5 AcOH. Recrystd. from MeAc, the acid decomps. 184°. An isomeric *tribromodiketocholanic acid*, m. 213–4°, was obtained from the mother liquor.

A. W. Dox

The biose of chitin. MAX BERGMANN, LEONIDAS ZERVAS AND EFIM SILBERKWEIT. *Naturwissenschaften* **19**, 20(1931).—By acetolysis of lobster chitin a disaccharide of glucosamine was obtained as a cryst. octa-Ac deriv., m. 289°, $[\alpha]$ 50° in AcOH, I no. (cf. B. and Machemer, *C. A.* **24**, 2877) 31.3 (calcd. 29.6). The new disaccharide, chitobiose, may be as useful for chitin study as cellobiose for cellulose research.

B. J. C. VAN DER HOEVEN

Cholesterol. XIII. Action of phosphorus pentasulfide. E. MONTIGNIE. *Bull. soc. chim.* [4], **49**, 73–5(1931); cf. *C. A.* **25**, 1256.—Cholesterol (I) in CS_2 was refluxed with a like wt. of P_2S_5 and yielded *thiocholesterol*, $C_{27}H_{45}SH$ (II), m. 191°, α_D −39°; (*di-Br deriv.* m. 152–3°; nitro deriv. m. 125°). II does not combine with $HgCl_2$ and does not give the Liebermann reaction. I reacts with white P and O_2 to yield a noncryst. *phosphorate* according to the equation: $-CH{:}CH- + P_2 + 2O_2 \longrightarrow$ $-CH.P(:O).O.P(:O).O.CH-$. Upon hydrolysis of this compd. $(OH)_2P(:O)OCHCH-PH(:O)OH$ was obtained. The Ag, Pb, Ba, Sn^{++}, Zn, Hg, U, Cu and Hg salts were prepd. The acid yields an *acetylated product*, m. 250°, decompg. about 200°. The OH group is left intact.

I. M. LEVINE

Ursolic acid. CHARLES E. SANDO. *J. Biol. Chem.* **90**, 477–95(1931).—Ursone (I) was isolated from the leaves of *Arctostaphylos uva-ursi* by extg. with Et_2O, dissolving in EtOH contg. 1% NaOH and repeatedly crystg. from aq. EtOH contg. a little NaOH; by decompn. of the Na salt with HCl a yield of 30 g. was obtained from 2.2 kg. leaves.

On fractional crystn. from 75% EtOH, 4 out of 5 fractions gave a const. m. p. at 284–5° and formula $C_{30}H_{48}O_3$. *Prunol*, prepd. from leaves of *Prunus serotina* (Power and Moore, *C. A.* **4**, 2182) in the same way, and *malol*, prepd. from apple peels as previously described (Sando, *C. A.* **18**, 1003) both had the same formula and m. 284–5°. The malol was obtained by the above method and also by fractional crystn. without conversion to the Na salt, to avoid the possibility of change by the alkali. The identity of these 3 compds., as claimed by van der Haar (*C. A.* **18**, 2511), is confirmed by analysis and by crystal data, but the formula, based on 92 combustions, is as above and not $C_{31}H_{46}O_3$, as van der Haar states. The *di-Ac derivs.* of all 3 compds., prepd. in good yield by boiling several hrs. with excess Ac_2O, were also identical. From 4.56 g. of the di-Ac deriv. by refluxing 3 hrs. with 70% EtOH, 4 g. of the *mono-Ac deriv.*, $C_{29}H_{46}(OAc)CO_2H$ (II), m. 289–90°, was obtained. From I was prepd. by boiling with excess Me_2SO_4 in MeOH and NaOH, extn. with Et_2O and crystn. from 70% EtOH, *Me ursolate* (III), $HOC_{29}H_{46}CO_2Me$, m. 170.5–1.5°. Acetylation of III gave a *mono-Ac deriv.*, m. 246–7°. Prepn. of the same compd. by action of $SOCl_2$ on II, followed by boiling with MeOH, confirmed the HO acid formula. The name *ursolic acid* is therefore adopted for I, for prunol and for malol. The following derivs. were also prepd.: from 1 g. I by treatment with excess *o*-$C_6H_4(CO)_2O$, 1 g. *phthalylursolic acid*, m. 264–5°; from 1 g. III by similar treatment, 0.7 g. *Me phthalylursolate*, m. 214–5°; from 2.3 g. I, suspended in 70% aq. EtOH, by making nearly alk. and boiling 1.5 hrs. with 1 g. $BzCH_2Br$, 2.85 g. *phenacylursolate*, m. 199–200°. K. V. THIMANN

Oxygenated organic compounds by synthesis from hydrogen and oxides of carbon. H. DREYFUS. Brit. 337,409, July 24, 1929. Compds. such as EtOH, acetaldehyde, HOAc and their homologs and esters are prepd. from H and C oxides or from compds. such as MeOH synthesized from them (with or without presence also of H and C oxides) by use of catalysts such as Fe, Ni or Co borates, silicates, phosphates or salts of other oxyacids of P. Various details and examples are given, and app. may be used having Cu or Cu-lined chambers or formed of steel contg. Mo, Mn, Co or Ni. Temps. up to 600° and pressures up to 500 atm. are mentioned as suitable. Cf. *C. A.* **25**, 1839.

Oxygenated organic compounds from methane and steam. H. DREYFUS. Brit. 337,410, July 24, 1929. Compds. such as EtOH, HOAc, AcH and their homologs and ketones are formed from CH_4 and steam at 200–500° and pressures up to 500 atm. or more, and the products may be varied by adding to the reaction mixt. C oxides, H or O, and inert gases such as N also may be present. Among the catalysts which may be used are Zn, Mg, Ca, Al, Cr, Mn, V, Mo, Ti, Fe, Co, Ni and rare earths, or their compds., such as oxides, As or S compds., phosphates, silicates or borates. Also there may be used mixts. of these with alkali or alk. earth compds., with each other, with Cu, Ag or Au, with compds. such as Zn vanadate, Zn chromate, Mn chromate, Zn tungstate or molybdate or with the corresponding salts of Mg, Ca or Al. App. of Cu or lined with Cu or of steel contg. V, Mn, Ni or Co is suitable.

Olefinic or aromatic hydrocarbons by catalytic conversion. I. G. FARBENIND. A.-G. Brit. 337,434, May 30, 1929. Chambers serving for conversions of this character are alternately heated (suitably to about 900°) and initial materials intermittently passed through them, while in assocd. operation with heat regenerators, and the heat regenerators are preferably made of material catalyzing the desired reactions such as firebricks impregnated with Cu salts or bricks made from fireclay and Si, or other refractory materials may be used such as alloys of Cr and Ni, ferro-Si or SiC. Initial materials which may be used include gases obtained by the degasification of carbonaceous materials with steam and (or) gases contg. O, and reaction gases from the de-

structive hydrogenation of coals, tars, mineral oils, etc., contg. homologs of CH_4. Various details and examples of procedure are given.

Olefin oxides from chlorohydrins. JOSEF WEBER, HANS SCHRADER and ERICH WIEDBRAUCK (to Th. Goldschmidt A.-G.). U. S. 1,792,668, Feb. 17. In reactions such as the production of ethylene and propylene oxides from chlorohydrins, there is established and maintained (in an app. which is described) a slowly flowing body of boiling aq. liquid having an extensive surface, and to this, at a point near the beginning of flow, there is supplied corresponding quantities of chlorohydrin soln. and of alkali, and the condensed olefin oxide vapors are collected.

Organic isocolloids. L. AUER and L. SUSZTEK. Brit. 337,735, April 24, 1929. See Fr. 694,339 (*C. A.* **25**, 1839).

Aminoalkyl and alkylaminoalkyl compounds. JOSEPH KLARER and FRITZ MIETZSCH (to Winthrop Chemical Co.). U. S. 1,793,176, Feb. 17. A described process comprises the reaction of a compd. of the general formula R_1R_2N-alkylene-halogen, wherein R_1 and R_2 stand for substituents of the group consisting of H and alkyl, with a compd. of the general formula halogen-MgR_3, wherein R_3 stands for a substituent of the group consisting of aryl and hydroaromatic residues and heterocyclic residues contg. N and decomposing the reaction product with water. Details are given of the production of β-$Et_2NC_2H_4Ph$, $Et_2N(CH_2)_3Ph$, $Et_2N(CH_2)_4Ph$, 1-$Et_2NCH_2CH_2C_6H_4OMe$-4, 1-$Et_2NCH_2CH_2C_6H_4Br$-4, 2-methyl-3-β-diethylaminoethylindole (b_2 171° and forming white crystals after manipulation with ether), 1-$MeNHCH_2CH_2C_6H_4OMe$-4 and a base of the formula $PhCH_2CH_2NH_2$.

Replacing amino groups by halogen in aromatic and aliphatic compounds. RICHARD KUHN and ERNST EICHENBERGER. Swiss 141,750, Oct. 30, 1928. Addn. to 136,906 (*C. A.* **24**, 4305). The method of 136,906 is improved by removing the N atom from the diazonium halide compd., formed by diazotizing the amine in the presence of a high halogen concn., by radiation. In the example, the diazonium chloride obtained by diazotizing *o*-toluidine in the presence of a paste of $ZnCl_2$ and NH_4Cl, is subjected to the radiation of a Hg lamp, this induces the evolution of N.

Methylarylamines. EDGAR C. BRITTON and WM. H. WILLIAMS (to Dow Chemical Co.). U. S. 1,793,993, Feb. 24. In making an *N*-methyl deriv. of an arylamine such as dimethyl-*p*-toluidine, reaction is effected between the arylamine and MeOH with the addn. of a relatively small proportion of MeBr.

Sulfonating aromatic amines. ARTHUR R. MURPHY and JOSEPH B. OESCH (to Newport Chemical Corp.). U. S. 1,794,861, March 3. For introducing a sulfo group in *o*-position to the NH_2 group, an aromatic amino compd. such as *m*-xylidine or β-naphthylamine is treated with SO_3 in an inert solvent such as $C_2H_2Cl_4$.

Polymers of vinyl alcohol. I. G. FARBENIND. A.-G. (Fritz Klatte and Arthur Zimmermann, inventors). Ger. 514,593, Nov. 13, 1928. Halogenated polyvinyl esters are saponified with NH_4OH. Thus, polyvinyl chloroacetate is saponified with aq. NH_4OH.

Esters of organic acids and polyhydric alcohols. I. G. FARBENIND. A.-G. (Martin Luther and Walter von Knilling, inventors). Ger. 514,503, June 10, 1927. Small quantities of metal soaps are added during the esterification in the liquid phase. Thus, stoichiometric amts. of olive oil, fatty acid and glycerol are heated in a high vacuum to 170-250° with addn. of 0.2% Mg oleate.

Esters of glycolic acid. I. G. FARBENIND. A.-G. Brit. 337,609, Nov. 8, 1929. Dry anhyd. alkali metal or alk. earth metal salts of chloroacetic acid are heated with aliphatic alcs. such as ethyl, butyl or allyl alcs., 1,3-butylene glycol, glycerol or cyclohexanol, in the presence of an esterifying agent (generally above 100° and suitably under pressure). Examples are given of the production of the ethyl, butyl and allyl esters and that of 1,3-butylene glycol.

Esters and amides of 2-aminonaphthalene-3-carboxylic acid. I. G. FARBENIND. A.-G. (Ludwig Sander, inventor). Ger. 514,596, July 15, 1928. Alc. phenol, NH_4OH, or primary or secondary amines (except acyclic aliphatic secondary amines) is caused to react on 2,3-naphthoisatoic acid anhydride. Bases may be present. Thus, alc. NH_4OH contg. 5% NH_3, if stirred with the anhydride for 3 hrs. at 50°, gives a 60% yield of 2-aminonaphthalene-3-carboxamide, m. 234-236°. Several other examples are given.

Stabilizing thiocarbanilide solutions. I. G. FARBENIND. A.-G. (Philipp Siedler and August Moeller, inventors). Ger. 494,919, Jan. 29, 1928. Supersatd. solns. of thiocarbanilide in aromatic amines or heterocyclic bases are stabilized by addn. of synthetic or natural resin. Thus, a soln. of thiocarbanilide in *o*-toluidine is stabilized by addn. of colophony, turpentine basic waste resin and thick tar and cooling to —15° for 2 hrs.

Purifying benzanthrones. IVAN GUBELMANN, ROBERT J. GOODRICH and EDWARD T. HOWELL (to Newport Chemical Corp.). U. S. 1,794,848, March 3. A reaction mass comprising benzanthrone and assocd. impurities in concd. H_2SO_4 is dild. with water to a concn. of H_2SO_4 in which benzanthrone is relatively insol., and the benzanthrone is extd. by means of a selective solvent such as toluene which is immiscible with the H_2SO_4 and is then recovered from the solvent. Cf. *C. A.* **25**, 1539.

Substituted guanidines. EDUARD TSCHUNKER and HELMUTH MEIS (to I. G. Farbenind. A.-G.). U. S. 1,794,875, March 3. See Ger. 502,045 (*C. A.* **24**, 4791).

Acenaphthene derivatives. I. G. FARBENIND. A.-G. (Ernst Runne, inventor). Ger. 517,264, Aug. 27, 1929. 5-Hydroxyacenaphthene and its derivs. are prepd. by heating 5-aminoacenaphthene and its derivs. with water and a mineral acid or acid salt. Thus, 5-aminoacenaphthene may be heated for 8 hrs. at 200° with H_2SO_4 of about 10% concn. The prepn. of *5,6-dihydroxyacenaphthene*, m. 196°, from the diamino compd. is also described.

Benzophenone derivatives. I. G. FARBENIND. A.-G. (Sebastian Gassner and Berthold Bienert, inventors). Ger. 517,478, Feb. 14, 1929. Di- and tri-carboxylic acids of alkoxybenzophenones and their substitution products are prepd. by oxidizing alkoxy-mono- or -di-methylbenzoyl-*o*-benzoic acids or their substitution products with $KMnO_4$ in alk. soln. Thus, 4'-methoxy-5'-methylbenzoyl-*o*-benzoic acid yields *4'-methoxybenzophenone-2,5'-dicarboxylic acid*, m. 234–5°. Examples are given also of the prepn. of *2'-methoxybenzophenone-2,4'-dicarboxylic acid*, m. 249–50°, *2'-methoxybenzophenone-2,5'-dicarboxylic acid*, m. 238–9°, *2'-methoxy-5'-chlorobenzophenone-2,4'-dicarboxylic acid*, m. 202–4°, *2'-methoxybenzophenone-2,3',5'-tricarboxylic acid*, m. 140–2°, *2'-methoxy-3-chlorobenzophenone-2,5'-dicarboxylic acid*, m. 294–6°, and *2'-methoxy-3,5'-dichlorobenzophenone-2,4'-dicarboxylic acid*, m. 219–21°. Cf. *C. A.* **25**, 1538.

Safrole derivatives such as protocatechuic aldehyde and isoeugenol. FRITS E. STOCKELBACH. U. S. 1,792,716, Feb. 17. It has been found that, contrary to previous investigations, safrole yields, when heated with alc. potash to a temp. of 140–170°, a mixt. of two isomers, namely, 4-alkoxymethoxy-3-hydroxy-1-propenylbenzene, and 4-hydroxy-3-alkoxymethoxy-1-propenylbenzene, and that when this mixt. is subjected to the action of certain oxidizing agents, only the 4-hydroxy isomer is oxidized, while the 3-hydroxy isomer remains unoxidized and is readily recoverable. This makes possible the com. production of protocatechuic aldehyde and of obtaining as a by-product isoeugenol. Numerous details of procedure are described.

Safrole derivatives such as vanillin and isochavibetol. FRITS E. STOCKELBACH. U. S. 1,792,717, Feb. 17. When the isomeric reaction product produced by heating safrole with alc. KOH at 140–170° (see preceding abstr.) is methylated a product contg. a mixt. of methyl ethers of the two isomers is obtained, and upon heating this resulting product in a weak acid soln., the mixed ether group is split off with the evolution of formaldehyde and an alc. and the formation of isoeugenol and its isomer isochavibetol. When this mixt. of isoeugenol and isochavibetol is subjected to the action of certain oxidizing agents, only the 4-hydroxy isomer, that is, isoeugenol, is oxidized, while the 3-hydroxy isomer, that is, isochavibetol, remains unoxidized and is readily recoverable. This makes possible the com. production of vanillin from safrole, and of obtaining as a by-product isochavibetol. Various details of procedure are described.

***N*-Substituted derivatives of aromatic aminohydroxy and polyamino compounds.** I. G. FARBENIND. A.-G. Ger. 514,747, June 18, 1927. Addn. to 499,826. The methods of 499,826 (*C. A.* **24**, 4521) and 512,406 (*C. A.* **25**, 1036) for producing *N*-substituted amines of aromatic aminohydroxy and polyamino compds. are modified by replacing the aliphatic, heterocyclic and hydroaromatic linked N, by N in the form of alkylaminoalkyl compds. contg. two or more N atoms capable of conversion into strongly basic polyamino compds. Thus, 1-amino-3-methoxy-4-isopropoxybenzene and the dihydrochloride of ethyldiethylaminoethylaminoethyl chloride are fused together at 100–110° for 8 hrs. to give the base 3-MeO-4-iso-$PrOC_6H_3NHCH_2CH_2NEtCH_2CH_2NEt_2$. Other examples are given.

Organic compounds of lithium. KARL ZIEGLER. (Herbert Colonius, inventor.) Ger. 512,882, Oct. 15, 1929. Org. compds. of Li with the metal linked directly to C are obtained by the reaction of org. halogen compds. with Li in a solvent indifferent to Li alkyl and Li aryl compds., at temps. at which the reaction velocity between the Li alkyl or aryl compds. and the halogen alkyl or aryl compds. is low. Thus, Li wire or dust is added to abs. ether and PhBr added to produce a 70–80% yield of PhLi and LiBr. Other examples describe the production of MeLi and BuLi.

Aliphatic arseno compounds. CHARLES S. PALMER (to Parke, Davis & Co.).

U. S. 1,794,119, Feb. 24. Various examples are given for the production of arseno compds. some of which are suitable for combating spirochetes and trypanosomes. Na arsonopropionate and Na hypophosphite, in a 15% H_2SO_4 soln., on standing yield a product of the probable formula $HO_2CCHMeAs:AsCHMeCO_2H$. α-Arsonocaproic acid and hypophosphorous acid soln. produce a similar deriv. with C_4H_9 instead of CH_3 in both positions. Na arsonopropionate, $AsCl_3$ and Na hypophosphite produce $HO_2CCHMeAs:As.As:AsCHMeCO_2H$ and the same product may be obtained from NaOH, As_2O_3, α-bromopropionic acid, HCl and hypophosphorous acid. Crude β-hydroxyethylarsonic acid, As_2O_3, water and hypophosphorous acid yield a product contg. 70–72% As. Arsanilic acid, Na arsonoacetate, Na hypophosphite and HCl produce a product of which the middle fraction is nearly pure hydrochloride of *p*-aminophenylarsenoacetic acid. Arsenoacetic acid, 3,3′-diamino-4,4′-dihydroxyarsenobenzene.2HCl, dissolved in 10% NaOH soln., warmed on a steam bath in a current of N, cooled and neutralized with HCl, yield a product which is probably 3-amino-4-hydroxyphenylarsenoacetic acid, and a similar reaction may be effected in pyridine.

Aluminum alcoholates. Felix Kaufler and H. Georg Stangler (to A. Wacker Ges. für Elektrochemische Industrie). U. S. 1,793,935, Feb. 24. See Brit. 334,820 (*C. A.* **25**, 1265).

Triaryl phosphates. Imperial Chemical Industries, Ltd. Ger. 517,339, Oct. 19, 1929. See Brit. 322,057 (*C. A.* **24**, 2762).

Complex salts of iron. I. G. Farbenind. A.-G. (Hans Schmidt and Heinrich Jung, inventors). Ger. 514,504, May 1, 1929. See Brit. 335,965 (*C. A.* **25**, 1950).

Alkali salts of halohydroxybenzoic acid esters. Walther Schoeller and Hans Allardt (to Schering-Kahlbaum A.-G.). U. S. 1,793,021, Feb. 17. Esters of the general formula $3,4,5\text{-}X'(MO)X''C_6H_2CO_2R$ in which M represents an alkali-forming metal, X′ a halogen atom, X″ a halogen atom or H, and R an alkyl group, such as the Na salt of the 3,5-dibromo-, 3-bromo- or 3-iodo-4-hydroxybenzoic acid ethyl ester, are sol. in water with neutral reaction, "comparatively sol." in hot alc., insol. in petr. ether and benzene and *possess disinfecting properties*. They may be formed by the reaction of the corresponding acids with an alk. compd. such as Na_2CO_3.

Alkali metal salts of toluenesulfonehaloamide. I. G. Farbenind. A.-G. (Heinrich Günzler, inventor). Ger. 514,802, Oct. 19, 1924. $CaCl_2$ is caused to react on a concd. aq. soln. of the amide or its salts and simultaneously or subsequently treating the mixt. with an alkali metal salt which causes the pptn. of the Ca and leaves the desired alkali salt of the amide in the liquid from which it can then be obtained. Glauber's salt and calcined soda are mentioned as the alkali metal salts in examples.

Sodium *p*-hydroxyphenylarsonate. Union chemique belge S. A. Ger. 514,746, June 11, 1929. See Brit. 333,023 (*C. A.* **25**, 525).

Calcium formaldehydesulfoxylate. Max Baslen and Emil Rieger (to General Aniline Works). U. S. 1,793,152, Feb. 17. A difficultly sol. Ca formaldehydesulfoxylate is produced by acting on a soln. of an alkali metal formaldehydesulfoxylate with a sol. Ca salt such as $CaCl_2$ together with a hydroxide or carbonate of Ca or of an alkali metal.

Zinc oxide catalysts for methanol synthesis. Walter Bader and Stanley J. Green (to Celanese Corp. of America). U. S. 1,793,350, Feb. 17. A catalyst suitable for use in producing MeOH from H and C oxides is prepd. by heating a $ZnCO_3$ gel at a temp. not exceeding that at which the catalyst is to be used.

Aliphatic acids. H. Dreyfus. Brit. 338,187, Aug. 12, 1929. HOAc, propionic acid and similar acids are concd. by extg. their aq. solns. with a solvent such as ether, EtOAc or acetone oil and then adding a liquid such as a hydrocarbon or suitable halogenated hydrocarbon to the ext. to ppt. the dissolved water, and salts also may be used to limit the soly. of the solvent in water. Various details of app. and operation are described. Cf. *C. A.* **24**, 3250.

Acetic acid. Destilacija Drva D. D. Ger. 517,497, Sept. 29, 1928. Gases contg. AcOH vapor are washed at atm. temp. with a mixt. contg. about equal parts of a non-acetylizable base b. above 150°, *e. g.*, quinoline or $PhNMe_2$, and a high-boiling hydrocarbon or hydrocarbon mixt., *e. g.*, anthracene oil or paraffin oil. AcOH is recovered from the used washing mixt. by distn. Cf. *C. A.* **25**, 524.

Acetic acid. Soc. française de catalyse generalisee. Brit. 338,329, Jan. 26, 1929. See Fr. 36,719 (*C. A.* **25**, 970).

Aromatic mercaptocarboxylic acids. Chemische Fabrik von Heyden A.-G. (Kurt Buchheim, inventor). Ger. 514,507, June 21, 1928. Metallic compds. of aromatic mercaptans are treated with CO_2 under high temp. and pressure. Thus, an 85–88% yield of 1-mercaptobenzene-2-carboxylic acid is obtained by the action

of CO_2 on the Na salt of thiophenol at 150–190° and 36–50 atm. Other examples are given.

1-Methyl-5-chlorobenzene-2-carboxamide-3-thioglycolic acid. I. G. FARBENIND. A.-G. (Norbert Steiger, Erwin Hoffa and Hans Heyna, inventors). Ger. 514,505, April 1, 1927. 1-Methyl-2-cyano-5-chlorobenzene-3-sulfonic acid chloride is reduced with a metallic reducing agent in the presence of a strong mineral or org. acid and with addn. of an inert org. solvent for the sulfonic acid chloride, and condensing the resulting 1-methyl-5-chlorobenzene-2-carboxamide-3-mercaptan with $ClCH_2CO_2H$ at suitable temps. Examples are given.

Purifying sulfonic acids. GRIGORI PETROFF. Ger. 517,156, Jan. 18, 1927. Sulfonic acids of high mol. wt. are freed from unsulfonated material, resins, H_2SO_4, etc., by mixing them, or their solns. in water and (or) alc., with porous cellulosic material, *e. g.*, saw dust, wood meal, or hydrocellulose. The mixt. is dried and then extd. in turn with benzine, C_6H_6, and EtOH. The first extn. removes mineral oils, resins, etc., the sulfonic acids being taken up in the later extns. H_2SO_4 remains in the cellulosic material. The method may be applied to octahydroanthracenesulfonic acid, alkylnaphthalenesulfonic acids, sulfo-aromatic fatty acids, etc. An example is given.

Anhydro-*N*-pyridiniumsulfonic acid. PAUL BAUMGARTEN. Ger. 514,821, Mar. 17, 1926. SO_3 or SO_3-yielding agents such as oleum, $ClHSO_3$ or its esters, or SO_2Cl_2 is caused to react on pyridine or its *C*-alkyl homologs, alone or in presence of a diluent. Thus, a 90% yield is obtained by the action of SO_3 on a soln. of pyridine in CCl_4. Other examples are given.

Acetic anhydride, etc. H. DREYFUS. Brit. 336,668, July 19, 1929. Aliphatic acid anhydrides are made by heating the vapor of the corresponding acid in contact with a catalyst supported upon or mixed with asbestos, *e. g.*, HOAc vapor is passed rapidly through a Cu tube at 400–500° contg. Ca tungstate upon asbestos and the anhydride formed is sepd. by fractional condensation. Cf. *C. A.* **25**, 1538.

Tetrahydrofurfuryl alcohol. GEORGE D. GRAVES (to E. I. du Pont de Nemours & Co.). U. S. 1,794,453, March 3. Furfural is heated under pressure with H, a Ni catalyst and water.

Formaldehyde from oxidation of hydrocarbons. H. HARTER. Brit. 337,407, June 24, 1929. An app. is described for oxidizing gaseous or readily volatile hydrocarbons by air (or air enriched with O) which, just before use in the reaction, is passed through an elec. flaming arc by which N oxides are formed which facilitate the production of CH_2O. The oxidation may be assisted by catalysts such as Cu, Ag, Co or Mn, assocd with silica gel or active C.

Acetaldehyde from acetylene. I. G. FARBENIND. A.-G. Ger. 514,591, Nov. 9, 1916. Addn. to 504,862 (*C. A.* **25**, 524). C_2H_2 is treated with catalyzers consisting of Fe compds. which are converted by C_2H_2 into reducible oxides. Thus, powd. hydrated $Na_2SiO_3.Al_2(SiO_3)_3$ is suspended in a soln. of $FeCl_3$ and the Fe pptd. by concd. NH_4OH. The ppt. is washed, pressed and dried, and C_2H_2 is led over it at 350° to give AcH. Other examples are given.

Acetone from isopropyl alcohol. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 337,566, Oct. 10, 1929. Dehydrogenation of isopropyl alc. at temps. below 400° (preferably not over 350°) is effected in the presence of catalysts such as Cu, MnO_2, BaO_2, metals of the Pt group, ZnO, CdO, blue W oxide, Mn oxide, V pentoxide, MgO, or oxides of Be or Zr, with the addn. of small quantities (preferably not over 1%) of Th oxide, Na_2CO_3, Ce oxide, or of oxides of Zn or Zr if these are used merely as auxiliary addns. The catalyst may be regenerated with steam or air or both, by heating, followed by reduction.

Urea. I. G. FARBENIND. A.-G. Brit. 337,394, July 29, 1929. Various details are described relating to the distn. of crude melts contg. urea together with NH_4 carbonate or NH_4 carbamate and water, obtained in the production of urea from NH_3 and CO_2 under pressure, to recover NH_3 and CO_2. During the stage of the distn. effected at temps. over 150° under pressures sufficient to cause the distillate to collect as a liquid, an excess of NH_3 over that required to combine with all the CO_2 present in the distn. app. is continuously maintained in the app. in order to check decompn. of urea.

Nitrobenzene purification. SYLVESTER BOYER (to General Elec. Co.). U. S. 1,793,304, Feb. 17. The material is passed through fuller's earth, then treated with Al oxide and distd.

1,2,3-Trihalobenzenes. I. G. FARBENIND. A.-G. (Richard Herz and Eduard Albrecht, inventors). Ger. 517,429, Oct. 6, 1927. See Fr. 661,490 (*C. A.* **24**, 379).

Dimethylaniline. EDGAR C. BRITTON and WM. H. WILLIAMS (to Dow Chemical

Co.). U. S. 1,794,057, Feb. 24. A mixt. of aniline and MeOH is heated with addn. of a small proportion of MeBr.

2,6-Xylidine. IMPERIAL CHEMICAL INDUSTRIES, LTD. Ger. 517,338, Mar. 1, 1930. See Brit. 328,418 (*C. A.* **24**, 5309).

Benzidine and its substitution products. HENRY J. WEILAND and IVAN GUBELMANN (to Newport Chemical Corp.). U. S. 1,794,097, Feb. 24. For effecting purification of benzidine or derivs. such as *o*-tolidine or bi-*o*-anisidine, a salt of the impure material such as the hydrochloride or sulfate is treated with an alk. aq. soln. such as NaOH to give an alk. reaction to the resulting soln. and with a sufficient quantity of a water-immiscible org. solvent to dissolve the benzidine compd. when hot; insol. impurities are sepd., the benzidine compd. is crystd. from the org. solvent and is recovered without any intermediate isolation.

Carbazoles. I. G. FARBENIND. A.-G. (Friedrich Stolz, Walter Kross, Gustav Ehrhart and Hans Schlichenmaier, inventors). Ger. 514,822, Jan. 29, 1929. Perhydrogenated carbazoles are obtained by treating carbazole or its *N*-alkyl derivs. with H under pressure and at high temps., in the presence of a catalyzer formed by heating a Ni salt alone or mixed with another metal (preferably of the Fe group) with a carrier such as SiO_2, to a temp. of above 400°. Examples are given. Cf. *C. A.* **25**, 801.

Isatins. I. G. FARBENIND. A.-G. (Hans Colombara, inventor). Ger. 514,595, Mar. 28, 1928. Isatins are obtained by treating oxamyl halides of primary amines of the general formula R·NH·CO·CO·halogen (R = a residue of the benzene series, with at least one substituent) with a condensing agent. Thus, 5,7-dimethylisatin (m. 242°) is obtained by treating 2,4-dimethyl-1-phenyloxamyl chloride with $AlCl_3$. Many other examples are given.

1-Phenyl-2,3,4-trimethyl-5-pyrazolone. I. G. FARBENIND. A.-G. (Max Bockmühl, Karl Streitwolf, Alfred Fehrle and Walter Herrmann, inventors). Ger. 514,823, May 7, 1929. More than 5 mols of CH_2O is caused to react on 1-phenyl-2,3-dimethyl-5-pyrazolone or on methylenebis(1-phenyl-2,3-dimethyl-5-pyrazolone) in the presence of concd. HCl. The reaction takes place at raised temp. and under pressure. Examples are given. Cf. *C. A.* **24**, 4524.

Antipyrine. ERNEST F. GRETHER and JOSEPH P. BELSLEY (to Dow Chemical Co.). U. S. 1,792,833, Feb. 17. Methylation of compds. such as 1-phenyl-3-methyl-5-pyrazolone in the production of antipyrine is effected with MeOH and an alkyl halide such as EtBr, the alkyl radical of which contains at least 2 C atoms.

α-Hydroxy-β′-iodopyridine. CURT RATH. U. S. 1,793,962, Feb. 24. In forming compds. of this character, an α substituted β′ aminopyridine is diazotized and the diazo soln. is caused to react with a metal iodide such as KI. The α hydroxy-β′-iodopyridine is a white cryst. compd. sol. in water. Cf. *C. A.* **24**, 2472.

Menthol. WALTER SCHOELLER, HANS JORDAN and REINHARD CLERC (to Schering-Kahlbaum A.-G.). U. S. 1,793,020, Feb. 17. See Ger. 508,095 (*C. A.* **25**, 717).

Menthol. SCHERING-KAHLBAUM A.-G. (Walter Schoeller, Hans Jordan and and Reinhard Clerc, inventors). Ger. 514,594, July 16, 1927. Addn. to 512,719 (*C. A.* **25**, 1260). The condensation product from acetone and *m* cresol is acetylated and the product hydrogenated until 8 H atoms are taken up. Sapon. then gives menthol. Examples are given. Cf. *C. A.* **25**, 717.

Sterols. I. G. FARBENIND. A. G. (Robert Griessbach and Otto Ambros, inventors). Ger. 517,499, April 7, 1927. See Brit. 322,465 (*C. A.* **24**, 2760).

Styrene and its homologs. I. G. FARBENIND. A.-G. Brit. 338,262, Sept. 10, 1929. See Fr. 682,569 (*C. A.* **24**, 4523).

The porphyrins. XXVII. The mechanism of iron introduction into porphyrins and isolation of crystalline hemes. H. FISCHER, ALFRED TREIBS and KARL ZEILE. *Z. physiol. Chem.* **195**, 1–27(1931); cf. *C. A.* **25**, 118.—In the various hemins the Fe is

tervalent. With few exceptions all contain the group FeCl substituted in the NH groups of 2 pyrrole rings. A curious fact is that the prepn. of these Fe complexes from porphyrins is best accomplished by the use of Fe^{++} instead of Fe^{+++}. The explanation of Haurowitz that a $(:N)_2Fe$ complex is first formed which immediately reacts with HCl to form $(:N)_2FeCl$ and H was tested experimentally with protoporphyrin in an atm. of N. Neither free H nor the hydrogenation product mesoporphyrin could be detected; the product obtained was hematoporphyrin. On the other hand, the treatment of mesoporphyrin with Fe^{++} in the absence of O gave a product with the characteristic spectrum of hemin. The reaction is strikingly demonstrated by the use of an inverted V-tube, one arm contg. a soln. of porphyrin in AcOH, a little HCl and $Fe(OAc)_2$. The air is displaced by N and the app. sealed. When heat is applied to the mixt. the HCl distils to the other arm and the residual soln. suddenly changes color because of the formation of Fe complex. If the distillate is now poured back by tilting the tube the reaction is reversed and the original color restored. The process may be repeated 5–10 times until finally a partial oxidation results from secondary reactions. After air has been admitted the complex formation is no longer reversible. With $FeCl_3$ and pure AcOH or $PrCO_2H$ the complex is not formed unless high temps. are used, and then only partially, because of a reduction of Fe^{+++} to Fe^{++} by decompn. products. The addn. of Fe to a porphyrin thus occurs via an Fe^{++} complex. Such complexes for which the term *heme* is proposed (cf. Anson and Mirsky, *C. A.* **23**, 1428) have now been prepd. and isolated in cryst. form from etio-, proto- and meso-porphyrin and its ester. All are Cl-free even in the presence of Cl ions. When treated with pyridine they give an intense hemochromogen spectrum. The hemes are extremely unstable to HCl, the Fe is split off as Fe^{++} as shown by the Turnbull blue reaction with $K_4Fe(CN)_6$. They are easily oxidized to the stable Fe^{+++} complex especially in the presence of Cl ions. Only Fe^{++} can be introduced into the porphyrins. Since the Fe^{++} complex is more easily oxidized than the Fe^{++} salt, only a min. quantity of the latter is required, because the Fe^{+++} salt present effects the oxidation of the Fe^{++} complex. This institutes a chain reaction which proceeds almost as rapidly as that in which the required quantity of Fe^{++} is initially present. Atm. O plays an important role, as also the catalytic property of hemin itself. By using a technic which excludes the possibility of oxidation, *etioheme*, *protoheme*, *mesoheme* and *meso-ester heme* were obtained cryst. from the corresponding porphyrins. In the dry state they are more stable to atm. O than their solns. A cryst. hemochromogen was prepd. by addn. of pyridine to the meso-ester heme. Hemoglobin is probably a mol. compd. of heme with globin, the latter effecting a stabilization of the mol. O converts it to oxyhemoglobin which is still more stable. Methemoglobin, on the other hand, contains hematin with Fe^{+++} and is extremely stable to reducing agents. It is surprising that the spectrum of hemoglobin bears no resemblance to that of hemochromogen, such as might be expected on the assumption of a mol. compd. of heme and globin. A possible explanation may be its peculiar state of dispersion, since reduced hematin with native globin gives hemochromogen. A. W. Dox

The effect of radioactive emanations on the automatic activity of the frog heart with particular reference to the action of large doses of such radiations and to the antagonism of α- and β-rays. E. Polák *Arch. ges. Physiol.* (*Pflügers*) **226**, 659–75(1931). Arthur Grollman

Purinolytic enzymes of the human organism. Richard Truszkowski. *Biochem. J.* **24**, 1681–5(1930). Uricase was found to be absent from the livers of a new-born child and in 2 adults. Xanthine oxidase is present in liver exts. from the 12th to the 40th week of pregnancy. Benjamin Harrow

Denaturation of proteins. VII. Denaturation in the presence of alcohol. Norman Booth. *Biochem. J.* **24**, 1699–1705(1930); cf. *C. A.* **24**, 5314.—The speed of denaturation of hemoglobin has been detd. in the presence of alc. ranging from 0 to 30 vols. %, the temp. varying from 30° to 60.5°, and the p_H from 5.19 to 7.74. The min. point on the p_H velocity curve was shifted considerably from the neutrality point of water to the acid side by the addn. of alc. The critical increment of activation increased appreciably with the amt. of alc. present. Benjamin Harrow

Effect of light and salts on gelatin. Ada Galinsky. *Biochem. J.* **24**, 1706–15 (1930).—When gelatin is made insol. by treatment with dichromate and exposed to light, a change in the protein similar to denaturation takes place, but this involves no change in the Hausmann nos., nor in the digestibility of the protein. Cr is fixed as its sesquioxide. Coagulation probably takes place in 2 stages, the first being a chem. action, and the second, which is phys. in nature, produces the coagulation. B. H.

Enzymes and vitamins in present-day chemistry. H. C. Sherman. *J. Chem. Education* **8**, 652–60(1931). E. H.

Physico-chemical studies of phosphatides. KORETOSHI OSE. Gifu Imp. Coll. of Agr. (Japan), *Research Bull.* 2, 30 pp.(1930) (in German).—Com. egg yolk lecithin electrodialyzed for 1 month resulted in isolation of 2 cryst. substances, one white, m. 57.5°, $C_{126}H_{256}N_2PO_{11}$, the other brown, m. 50.5°, $C_{97}H_{188}NPO_{17}$. The latter is readily sol. in cold 95% EtOH, the former with difficulty. K. KITSUTA

The story of histamine. D. ACKERMANN. *Z. Biol.* 91, 73–4(1931). FRANCES KRASNOW

The disintegration of proteins by amides. Disintegration of casein in acetamide. E. CHERBULIEZ AND G. DE MANDROT. *Helv. Chim. Acta* 14, 163–83(1931).—Proteins in general are sol. in acid amides and when such solns. are heated, the proteins are disintegrated yielding substances of relatively low mol. wt. For instance, when finely divided casein suspended in molten $AcNH_2$ is heated to 200°, a mixt. is obtained, the mol. wt. of which fluctuates between 247 and 396. The elementary analysis and color reactions (biuret, Millons, xanthoproteic) of the mixt. were similar to those of casein. However, the COOH groups were free but the NH_2 groups were not. When the casein was subjected to the heat treatment 5 min. or less, the products gave a pos. biuret test immediately; otherwise the test was obtained only when the mixt. was allowed to remain in the presence of alkali for some time. C. and M. consider that the long heat treatment caused a profound change in the casein mol. and that the alkali polymerized the products to compds. capable of yielding the biuret test. They agree with previous workers that the open-chain mols. in casein are broken and transformed into closed-chain substances of lower mol. wt. I. M. LEVINE

Denaturation of proteins by urea and related substances. F. GOWLAND HOPKINS. *Nature* 126, 328–30, 383–4(1930).—If in a few cc. of egg albumin recrystd. by the method of Hopkins and Pinkus and freed from the NH_4 sulfate, or in a soln. of ordinary egg white, urea be dissolved and the soln. evapd. in vacuum, the urea denaturizes the protein so that the former can be extd. with H_2O, while the protein becomes wholly insol. A change in the p_H from 4 to 7 does not affect the acquired condition of the protein. The denaturized protein gives a red-purple color characteristic of a sulfhydryl reaction when tested with nitroprusside and NH_4OH. Nondenaturized proteins do not give this reaction, indicating that a mol. rearrangement has taken place. The assumption is made that the precursor of the active thiol group is a disulfide grouping not present in the native protein, but established on denaturation. Pos. results obtained with certain N-contg. substances and neg. with certain others indicated that to some degree at least a relationship exists between denaturizing power and constitution. An amide structure appears to be necessary, and in dialkyl compds. 1 amino group apparently must remain active. The effect of urea on protein varies in detail with the abs. and relative concns. of the 2 constituents. Concomitant with the mol. rearrangement are profound changes in the colloidal and general phys. properties of the protein. A study of these resulted in the development of a simple method of detg. the degree and rate of protein denaturation, which in its turn was used for further study of the phenomenon of protein denaturation. Serum proteins, on the whole, are affected by similar denaturants in a similar manner on evapn. Observed in soln. their behavior indicated that blood proteins are more resistant to dehydration, which characterizes the change from lyophil to the lyophobe condition. The behavior of euglobins has not been studied. B. S. LEVINE

The absence of asparagine among the biuret-free products of proteins hydrolyzed by enzymes. A. CLEMENTI AND D. TORRISI. *Boll. soc. ital biol. sper.* 5, 956–8(1930).—During the digestion of casein, egg albumin and peptone to the point of their complete transformation into biuret-free products by the successive action of proteolytic enzymes present in the gastric, pancreatic and enteric juices of the dog, and thus without the intervention of asparaginase, 95% (often 100%) of the amide N is set free as NH_3. The amide N present in biuret-free products is set free completely as NH_3 by guinea-pig serum in which asparaginase is present, by dog serum, or by dog enteric juice in which asparaginase is surely absent. Conclusion: During digestion of the protein mol. aspartic acid is liberated as such and not in the form of asparagine. Asparagine cannot be considered as one of the intermediate enzyme degradation products of protein. PETER MASUCCI

The action of phosphatase of the bones on glycerophosphoric acid. A. DE RIENZO. *Boll. soc. ital. biol. sper.* 5, 1034–6(1930).—The action of phosphatase on asymmetric α-glycerophosphoric acid was studied. The enzyme was prepd. according to the Robison method and purified by electroultrafiltration. The α-glycerophosphoric acid was prepd. according to the Karrer method. Five cc. of Na α-glycerophosphate (0.1332% soln.),

2 cc. of borate buffer soln. of varying p_H values and 0.5 cc. of a 1.5% soln. of the enzyme were placed in each of 3 test tubes. In another set, an equal vol. of equimol. soln. of β-glycerophosphate was used. After 24 hrs. at 37° the inorg. P in each tube was detd. by the Bell and Doisy colorimetric method. The results obtained show that bone phosphatase hydrolyzes α-glycerophosphoric acid more readily than β-glycerophosphoric acid. PETER MASUCCI

The kinetics of fermentation processes. The kinetics of invertase. E. AVTONOMOVA. *Biochem. Z.* 231, 13–24(1931).—The invertase reaction like the catalase reaction may follow the equation of a monomol. reaction but under various conditions the consts. calcd. on this basis may be either increasing or decreasing. Decreasing consts. for invertase are obtained when a very low sugar concn. and relatively high enzyme concn. are used. On the contrary, with high concn. of catalase and low concn. of H_2O_2 the consts. are increasing. Obviously, enzymes whose activity tends to deviate from the monomol. type do so in a definite direction, and in the case of catalase this is predominantly toward decreasing, whereas in the case of invertase toward increasing, values. This is not due to differences in the nature of these enzymes but rather to the fact that the H_2O_2 is a powerful agent which destroys the catalase whereas the invertase is inhibited by the reaction products. The following equations are proposed to describe every instance of the enzyme kinetics, where the activity either decreases or increases: $C_1 = 1/t(A - D) \times \log D(A - X)/A(D - X)$ and $C_1 = 1/t(A + D) \times \log A(D + X)/D(A - X)$, resp. The value D is proportional to the initial enzyme activity. S. MORGULIS

Changes in the chloride distribution in blood under the influence of ultra-violet radiation. JERZY GLASS. *Biochem. Z.* 231, 45–53(1931).—Intensive ultra-violet radiation causes 2–4 hrs. after the treatment a change in the Cl distribution in the blood, with a tendency to accumulation in the red cells, which may persist for 24 hrs. This indicates a shift in the blood acid-base equil. toward an acidotic condition. S. M.

Enzymic formation of an ester of mandelic acid. P. RONA, R. AMMON AND H. A OELKERS. *Biochem. Z.* 231, 59–66(1931).—In the presence of isomolar concns. of *l*- and *d*- mandelic acid and Bu alc. the esterase from human, pig and cat liver, or from pig pancreas and kidney forms the Bu ester of mandelic acid with equal velocity. Thus, the marked specificity of these esterases which was found previously in the study of the hydrolysis of mandelic acid esters is not observed in the enzymic esterification. S. MORGULIS

The enzymic transformation of guanidine to urea. NICOLAI N. IVANOV AND A. N. AVETISSOVA. *Biochem. Z.* 231, 67–78(1931). —*Aspergillus niger* grown in a peptone culture can utilize guanidine very well as a source of N if this is furnished in conjunction with glucose, when the guanidine is changed to urea and NH_3. This depends upon the presence in the mycelium of a guanidinase. The dry mycelium of *Aspergillus niger* contains only guanidinase and no urease and can change guanidine quantitatively to urea and NH_3. Boiling this dry mycelium destroys its guanidinase activity. S. M

The Boas benzidine reaction of the potato. T. YOSHIOKA. *Biochem. Z.* 231, 233–8(1931).—The potato enzyme described by Boas (*C. A.* 25, 307) which reddens benzidine is entirely unaffected at 50°, but is weakened in its action at 60° and is completely inactivated at 70°. The enzyme can be pptd. by half satn. with $(NH_4)_2SO_4$ or full satn. with $MgSO_4$, and is made insol. by alc or acetone. With kaolin one obtains an insol. ppt. which has the full enzyme activity, but the enzyme cannot be leached out. With $Al(OH)_3$ no adsorption could be obtained. KCN or $HgCl_2$ inhibits the enzyme activity. Ni powder has no effect. The enzyme shows a great tendency to become insol. Through $(NH_4)_2SO_4$ pptn. enzyme prepns. can be made poor in N and of good potency, but through acetone pptn. active prepns. are made which retain full enzymic activity permanently, but they are insol. S. MORGULIS

A protein ethereal sulfate compound from spleen. ALFRED EBEL. *Biochem. Z.* 231, 306–8(1931).—A kg. of fresh spleen is chopped up fine, mixed with 1 l. H_2O and 40 cc. *N* AcOH and heated to 70°. The coagulum is filtered off, and the filtrate is pptd. with 200 cc. 20% $Pb(OAc)_2$. After this is made alk. with NH_4OH the ppt. is sepd. and the clear filtrate is freed from Pb with H_2S. The final filtrate is evapd. *in vacuo* to a small vol. and again filtered. The addn. of twice the vol. of alc. causes no turbidity. The concentrate is dialyzed 48 hrs. and, after filtering, is once more concd. *in vacuo*. Treated with 10 times its vol. of alc. a thick ppt. is formed which is allowed to settle in the ice box and is collected on a hardened filter paper, washed with alc. and dried. This powder is dissolved in very little H_2O and again pptd. as before with 10 vols. alc., the ppt. washed with abs. alc. and ether This substance gives no Millon reaction, a weak tryptophan reaction and a Molisch test for carbohydrate. The substance can be salted

out by full satn. with $(NH_4)_2SO_4$, and contains about 1.70% S which is hydrolyzable with 10% HCl at 100°. S. MORGULIS

Studies on phosphatase. I. The kidney phosphatase of different laboratory animals. MASAKI UMENO. *Biochem. Z.* **231**, 317–23(1931).—The phosphatase activity of the kidney from different animals has been tested on a Na glycerophosphate substrate. The relative activity follows the series: hen>cat>dog>steer>toad>rabbit>guinea pig. The phosphatase content of the various portions of the kidney was: cortex>medulla>papilla. **II. The liver phosphatase of different laboratory animals.** *Ibid* 324–27.—The liver phosphatase activity is about half as strong as the kidney phosphatase, and is also differently distributed in the animal series: hen>rabbit>dog>guinea pig>frog. **III. The phosphatase content of the kidney and liver in experimental nephritis.** *Ibid* 328–33.—In exptl. nephritis the kidney phosphatase activity is reduced to $^1/_2$–$^1/_3$ of its normal value. The liver phosphatase activity during nephritis is also diminished but only to a small degree. **IV. The optimum temperature and the inactivation temperature of the kidney phosphatase.** *Ibid* 334–8.—The optimum temp. for the activity of the steer or dog kidney phosphatase is 42.5°. The enzyme is destroyed at a temp. between 60 and 65°. **V. The glycerophosphatase of leucocytes in blood.** *Ibid* 339–45.—The leucocytes of a leucemia patient were found to contain much phosphatase. One cc. rabbit leucocytes hydrolyzes 0.036 g. Na glycerophosphate per day, while the erythrocytes show no phosphatase action. **VI. The presence of phosphatase in bile and pancreatic juice.** *Ibid* 346–51.—Bile contains a very strong phosphatase, whereas pancreatic juice possesses only about half as much phosphatase activity. Saliva and gastric juice are free from phosphatase, but the mucosa of the stomach, duodenum and small intestine and the salivary gland are rich in phosphatase. Phosphatase is also present in the liver, pancreas and spleen. The phosphatase content of an organ is independent of that of its secretion. S. MORGULIS

Resistance of insulin to certain bacteria. A. A. SCHMIDT AND KLARA TULICHINSKAJA. *Biochem. Z.* **231**, 352–64(1931).—*B. coli communis*, *Staphylococcus aureus*, *Streptococcus hemolyticus* and some anaerobic bacteria from dog feces cannot inactivate insulin. However, it is possible to obtain from feces putrefactive organisms which do destroy insulin very vigorously. It is suggested that bacteria of the peptolytic group, devoid of proteolytic enzymes, do not inactivate the insulin, which is perhaps due to the similarity between the insulin and the protein mol. S. MORGULIS

Influence of ptyalin on starch. II. Effect of electrolytes. J. R. BROEZE. *Biochem. Z.* **231**, 365–84(1931); cf. *C. A.* **23**, 1917.—The action of dialyzed ptyalin solns. on the starch sol in the presence of small quantities of electrolyte has been studied by changes in the expression $y_s - y_0/y_0$ in the course of time. The symbol y, of course, refers to viscosity. Without electrolyte addn. the velocity of the change is very small, and is very much increased by the least concn. of all electrolytes, with only a small advantage in favor of cations with increasing valence. A cation lyotropy is not observed but in the univalent anions the increase in reaction velocity seems to coincide with the lyotropic series: $CNS<NO_3<Cl,F$. The SO_4 ion does not behave according to its lyotropic position. S. MORGULIS

Specificity of the α-glucosidases. H. KARSTRÖM. *Biochem. Z.* **231**, 399–403 (1931).—With a strain of *Bacillus coli* which ferments maltose, glucose and fructose but not sucrose it was shown that the α-glucosidase which is operative in the hydrolysis of maltose cannot hydrolyze sucrose. S. MORGULIS

The chemical constitution of serum proteins. IV. ANTON FISCHER AND ALFRED BLANKENSTEIN. *Biochem. Z.* **231**, 404–11(1931); cf. *C. A.* **25**, 977.—Two pathological sera showed a greatly increased sedimentation reaction and an abnormally high tryptophan content. A study of the seven different chem. fractions shows that, as compared with the normal serum, there was a diminution of the albumin and an increase of the globulin content; this increase was not shared by all globulin fractions but principally by the euglobulin, which is pptd. by NaCl. S. MORGULIS

Influence of pancreatin on collagen in the absence of neutral salts and buffer mixtures. I. A. KÜNTZEL AND O. DIETSCHE. *Biochem. Z.* **231**, 423–34(1931).—The pancreatin action is exerted chiefly at the beginning of the reaction, so that prolongation of the action is safe only so far as no bacterial effect comes into play. There is practically a direct relationship between the amt. of pancreatin and the extent of the hydrolysis but the curve nevertheless shows a tendency to flatten out gradually so that an excess of pancreatin does not present any serious danger of carrying the hydrolysis too far. The enzyme activity does not increase proportionally to the rise in temp., and from about 45° the increase becomes quite remarkable, and this factor must be guarded most cautiously to prevent injury to the skins treated with pancreatin. S. M.

Influence of pancreatin on collagen in the absence of neutral salts and buffer mixtures. II. A. Küntzel and O. Dietschb. *Biochem. Z.* **231**, 435–40(1931); cf. preceding abstr.—This is in general a corroboration and extention of Merrill and Fleming's expts. on the digestion of collagen by pancreatin (*C. A.* **21**, 1369, 2396). S. Morgulis

Relation between swelling and proteolysis of collagen. F. Nauen. *Biochem Z.* **231**, 441–5(1931).—Salts of benzoic, salicylic and *p*-hydroxybenzoic acids promote proteolysis in the same order as they increase the swelling. The digestion of collagen by pancreatin is definitely promoted by previous swelling. S. Morgulis

Influence of physical factors on blood catalase. II. The influence of some physico-therapeutic procedures on the blood catalase. A. I. Alexeev and K. I. Russinova. *Biochem. Z.* **231**, 460–71(1931); cf. *C. A.* **24**, 1397.—The blood catalase of man under const. phys. conditions is practically the same. The outside temp. influences the blood catalase very much and should therefore be considered in the detn. of the catalase content and index. Elec. warm baths diminish the activity of the blood catalase more the higher the temp. of the bath. In a similar manner hot water baths greatly diminish the activity of the blood catalase, while a CO_2 bath or plain baths of ordinary temp. have no effect. The Scharko baths under 2.5 atm. pressure greatly diminish the blood catalase, but this does not occur until 30 min. after the bath. Air baths produce no noticeable changes in the blood catalase content. S. Morgulis

Specific dynamic action of protein. Henry Borsook and Howard M. Winegarden. *Proc. Natl. Acad. Sci.* **17**, 75–91(1931).—Analyses of data on the relation of the increase in metabolism following ingestion of protein or amino acids and the efficiency of renal excretion show that the course of the sp. dynamic action parallels the course of N excretion. Of the sp. dynamic action, 25–60% is due to the work of renal excretion and the rest to N and C metabolism. This will explain previous anomalies in the sp. dynamic action of protein. The sp. dynamic action of protein is not necessarily due to the conversion of the deaminized fractions into glucose. D. S. Searle

The relation of life to electricity. II. The relation of stainability to electromotive force in tissues and in a variety of artificial substances, like esters, etc. R. Beutner and Jos. Lozner. *Protoplasma* **12**, 52–65(1931).—Many data are given of potential measurements of the system:

+ aq. saline	ester or alc. + fatty acid	ester or alc. + amine	aq. saline −

The relation between stainability and e. m. f.:

+ basophilic substance/acidophilic substance −

holds for fats, esters, alc., hydrocarbons, etc. B. A. Soule

The effect of ultra-violet radiation on the respiration of avian erythrocytes and yeast cells. Gy. Surányi and M. Vermes. *Magyar Orvosi Arch.* **30**, 585–90(1929).—Ultra-violet radiation under aerobic and anaerobic conditions of avian erythrocytes and yeast cells in Tyrode soln., at p_H 7.2, increases the O_2 consumption, measured by the method of Warburg. The increase is about 50%. Cyanide inhibits the increased part as well as the normal respiration. This effect is reversible. H. Tauber

X-ray analysis of bone and teeth. H. H. Roseberry, A. Baird Hastings and J. K. Morse. *J. Biol. Chem.* **90**, 395–408(1931).—From the analysis of x-ray spectrograms of bone powder a crystal structure similar to that of the apatites is deduced, resembling closely the structure of dahlite, $CaCO_3.nCa_3(PO_4)_2$, in which n is not less than 2 nor more than 3. Neither $CaCO_3$ nor $CaHPO_4$ exists as such in bone. The results of de Jong (*C. A.* **20**, 2602) and of Taylor and Sheard (*C. A.* **4**, 24) are confirmed. $Ca_3(PO_4)_2$ also has a crystal structure similar to that of the apatites, varying slightly with different samples, but entirely different from that of $CaHPO_4$. The crystal structure of enamel also resembles the apatite series, and can probably be represented as a close-packed hexagonal lattice, of which $a_0 = 20.8$ A. U., $b_0 = 12.0$ A. U., $c_0 = 8.82$ A. U., referred to orthorhombic axes. The results of equilibration expts. between serum and solns. of Ca salts are considered to be of doubtful biol. significance. K. V. Thimann

Studies on the dielectric constant of protein solutions. Jeffries Wyman, Jr. *J. Biol. Chem.* **90**, 443–76(1931); cf. *C. A.* **23**, 5074.—The dielec. const. of solns. of zein in 70% EtOH alc. was measured by the method previously described for high frequency (*C. A.* **24**, 3681) and by a new resonance method at lower frequencies. At wave length 4 m. the dielec. const. of the zein solns. is lower than that of the solvent by an amt. proportional to the concn. of protein (cf. Fürth, *C. A.* **17**, 1579) resembling in general behavior that of

amino acid solns. (cf. Hedestrand, *C. A.* 22, 3571). It rises with temp., becoming greater than the solvent at 60°. The dielec. const., however, rapidly increases with wave length up to 260 m.—the longest wave used—becoming up to 50% greater than the solvent, and indicating anomalous dispersion. The zein mols. are therefore highly polar and possess a permanent elec. moment of about 60×10^{-18} e. s. u. No change in dielec. const. occurs during gelation, from which W. deduces that only a small fraction of the mols. is involved in the network, and that the viscosity of the whole gel is not the true viscosity of the soln. given by Stokes' expression, since it is to this viscosity that the relaxation times of the mols. are related. The theory of dielec. consts. and the application to mol. structure are briefly discussed. K. V. THIMANN

The p_H of human mixed saliva irradiation for intraoral carcinoma. GEORGE S. SHARP. *Am. J. Roentgenol. Radium Therapy* 25, 266–70(1931).—The saliva p_H for the individual patient taken during the 3 phases of irradiation forms a curve, starting with an abnormally acid saliva (p_H 6.1), rising during the acute reaction (p_H 6.5) and returning approx. to the pre-irradiation value during the post-irradiation period (p_H 6.0). R. C. WILLSON

The effect of radiation on the acidity of the blood. HELEN Q. WOODARD AND HELEN R. DOWNES. *Am. J. Roentgenol. Radium Therapy* 25, 271–5(1931).—No consistent change was observed in the p_H, CO_2-combining power or lactic acid content of the blood of patients after they had received one skin erythema dose of high-voltage Röntgen rays. No significant change was observed in the p_H of the blood of rabbits after lethal doses of high-voltage Röntgen rays. R. C. WILLSON

The effect of Röntgen rays on the inorganic phosphorus content of blood and urine of patients with carcinoma. F. I. RIVOSH AND E. R. NOVOTELNOV. *Voprosy Onkologii* 3, 150–6(1930); *J. Am. Med. Assoc.* 96, 155.—A normal P content was found in most of the 81 patients before treatment. In 2 hrs. after the treatment a steady increase in the P content of the urine and of the blood of all the patients was observed. After 24 hrs. the blood P was still increased but the urine P was normal. The same results but with larger increases in the urine and blood P were observed after Röntgen and Ra therapy of sarcoma, seminoma and lymphogranuloma. The sugar content changed in inverse proportion to the P content. R. C. WILLSON

Rotation dispersion of optically active substances (KEESER) 2. Evolution of H_2S in the Bay of Krasnovodsk (ZABRIEV) 2. Phenomena of adsorption and protection in complex colloidal media (MARIE, MARINESCO) 2. The bile acids (WIELAND, NOGUCHI) 10.

Peroxidase preparations. W. SAILER. Brit. 337,405, April 25, 1929. Vegetable substances contg. peroxidases such as embryos of rye, wheat, rice, maize or barley or parts of plants such as potatoes or bran are treated with water and fermentation is allowed to proceed in the presence of substances which in the soln. form buffer substances such as oxides, hydroxides or carbonates of alkali, alk. earth or other metals, such as ZnO, or metals not acting as catalysts. After filtering off the solids, the filtrate is treated with a preservative such as alc., benzoic acid or benzoic acid esters.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

An exact rapid method for determination of water in blood and serum. M. DOLCH AND E. PORCHMUELLER. *Z. physiol. Chem.* 195, 28–34(1931).—The ordinary method of H_2O detn. by drying to const. wt. does not exclude 3 possible sources of error in samples contg. protein, *viz.*, adsorption, occlusion and chem. reaction. The method here described obviates these errors and is far more rapid, requiring only 10–15 min. It is based on the fact that the temp. at which a mixt. of EtOH and xylene in definite proportions becomes cloudy varies with the H_2O content of the EtOH. A calibration curve is first plotted for the abs. EtOH to be used. This is done by mixing 11, 11.5, 12, etc., cc. of H_2O with 100 cc. of the EtOH, then mixing a 20-cc. aliquot with 20 cc. of dry xylene in a suitable app. provided with thermometer and stirrer, immersing in a freezing mixt. and detg. the temp. at which turbidity develops. The curve, in which temp. is plotted against amt. of H_2O added, is a straight line. Detn. of H_2O in blood or serum is performed as follows: Pipet a 15-cc. sample into a tared 150-cc. Erlenmeyer flask and weigh the sample. Add exactly 100 cc. of the EtOH, mix thoroughly, boil 10 min. and allow the pptd. protein to settle. Pipet 20 cc. of the supernatant liquid into the app., add 20 cc. of xylene and det. the temp. of clouding. Locate this temp. on the calibration curve and read the corresponding wt. of H_2O from the other axis. This value $\times$ 100 ÷ wt. of

sample is the per cent of H_2O by wt. The per cent by vol. is the wt. of H_2O × the factor 6.667. Addn. of cholesterol or dried protein did not affect the results. The values obtained by this method are slightly higher than those obtained by drying the sample to const. wt. and are claimed to be more accurate. A. W. Dox

A new method for the quantitative estimation of dissolved protein in gastric contents. Walter Wolff and Erich Jochmann. *Arch. Verdauungskrankh.* **48**, 151–7 (1930).—To 5 cc. of the filtered gastric contents add 5 cc. of a reagent contg. 10% phosphotungstic acid, 0.5% HCl and 10% alc., centrifuge and wash the ppt. with H_2O 3 times. Then dissolve in 3% NaOH, add 3 drops of 20% $CuSO_4$ soln. and 3% NaOH up to 10 cc. Centrifuge and compare the clear violet supernatant fluid colorimetrically with standards. Lowest values (<500 mg. %) are commonly obtained in achylia gastrica. Normal values may be as high as 1000–1500 mg. %. H. Eagle

The Kaufmann method of blood-sugar determination. H. Heinemann. *Arch. Schiffs-Tropen-Hyg.* **34**, 559–61(1930).—The iodometric method of Kaufmann can be used upon one drop of blood. H. Eagle

The estimation of iodine in the thyroid glands of albino rats. C. Newcomb and G. Sankaran. *Indian J. Med. Research* **18**, 557–61(1930).—The gland is dissolved in 10% KOH, ashed, extd. with alc. and again ashed. The residue is dissolved in water, and the color which develops upon the addn. of H_2SO_4, Na arsenite, CS_2 and nitrose compared with standards. H. Eagle

The determination of bile pigments in the blood serum. Pius Müller and Ludwig Engel. *Klin. Wochschr.* **9**, 2304(1930). —The degree of absorption of light of wave length 4993 A. U. is an accurate index of the amt. of bilirubin in serum. The diazo reaction used in the van den Bergh test detects only 30–60% the quantity as detd. by the spectrophotometer. The normal value is 0.6–2 mg. %. There is no regular correlation between the amounts as detd. by the two types of test. The proportion of bilirubin adsorbed on serum protein when the latter is pptd. may vary from 30 to 70% of the total; moreover, contrary to van den Bergh, such adsorption occurs even in sera which give the indirect reaction. In jaundice, there is a parallel increase in the results obtained by the two methods. H. Eagle

The Meinicke-Klarungs reaction as a rapid micro method for inactivated sera. Ernst Meinicke. *Klin. Wochschr.* **9**, 2304–5(1930). —Good results are reported, although the test is not as sensitive as the technic employing active serum. H. E.

The use of coal gas in making anatomical preparations in natural color. A. Schultz. *Klin. Wochschr.* **10**, 213–4(1931). —Tissues may be kept in Jores soln. through which coal gas has been passed, for many weeks without losing their natural blood tinge. Even the color of the organs, such as that of the liver, heart muscle and fat, is preserved by the CO. Jores soln. consists of 5% formalin, 2.5% chloral hydrate and 5% of synthetic Carlsbad salts in water. The aeration with CO-contg. coal gas must be carried out immediately before the tissue is immersed. After 3–10 days, depending upon the size of the prepn., the tissue is placed in the permanent preserving fluid: 1000 cc. H_2O, 6000 cc. glycerol and 300 g. Na acetate. For strongly jaundiced organs it is necessary to omit the glycerol and to increase the salt to 500 g. per 1000 cc. H_2O. H. Eagle

Determination of cholesterol and lecithin. Evaluation of egg products. J. Tillmans, H. Riffart and A. Kühn. *Z. Untersuch. Lebensm* **60**, 361–89(1930). —The methods suggested by other workers are critically discussed. For cholesterol a modification of the method of von Szent Gyorgyi (*C. A.* **17**, 3197) is the most direct and accurate. A soln. of not more than 4 mg. of cholesterol in 2 cc. of warm acetone is evapd. on a water bath with 1 cc. of a 2% soln. of digitonin in 80% alc. until 1.5 cc. remains. After 15 min. at room temp. the mixt. is filtered on a sintered glass crucible enclosed in a jacket through which steam can be passed, the ppt. transferred with acetone and twice washed with Et_2O, followed by 3 washes with $CHCl_3$, 2 with Et_2O, 1 with acetone and 1 with cold H_2O (1.5 cc. at a time). The suction is adjusted to filter 1 drop per sec., and the ppt. should always be covered with liquid to protect it from the air. Steam is then passed through the jacket, ten 1.5-cc. portions of H_2O are added, and the washing is finished with the full suction of the pump. The suction and heating are continued while 10 cc. of a clear 1% soln. of $K_2Cr_2O_7$ in concd. H_2SO_4 is slowly pipetted on the ppt. so as to fill ¼ of the crucible. The crucible is washed with 3 1-cc. portions of cold H_2O, sucked well and the total filtrate collected. The oxidation is complete in 1 hr., and 100 cc. of H_2O and 10 cc. of 5% KI soln. are added. The liberated I is titrated with 0.1% starch soln. for every 10 cc. of chromic acid taken, allowance being made for the blank titration. The mean of 15 expts. with pure cholesterol showed that the vol. of $Na_2S_2O_3$ soln. equiv. to the chromic acid consumed, divided by 8.7, gives the cholesterol content in mg. for 0.5–4.0 mg. The factor for phytosterol was 7.9; the m. ps. were 145° and 136°

for the 2 sterols, recrystd. from abs. EtOH, and 114° and 126°, resp., for their acetates. Egg products are first dried on the water bath with sand, extd. in a Soxhlet app. with Et_2O, evapd. and the residue is dried at 100° and weighed. A weighed portion is then dissolved in warm acetone, filtered, dild. to a suitable vol. with acetone and the above procedure followed. This gives free cholesterol. Another portion of the ethereal ext. is then sapond. on the water bath for 1 hr. with a 20% alc. soln. of KOH, the residue dried, mixed with sand and extd. as before to give the cholesterol after sapon. Results are given for various egg and pastry products. *Lecithin* was detd. by various methods, the technic giving the most accurate results consistent with the time consumed is based upon the Juckenack test (*Z. Untersuch. Lebensm.* 8, 97(1904)). The powd. 10-g. sample is extd. for 3 hrs. with hot alc. in a Soxhlet app., and the residue left on evapn. of the ext. is warmed with 15 cc. of perhydrol and 5–10 cc. of concd. H_2SO_4 until brown in color. The cool mixt. is dild. to 100 cc., 25 cc. neutralized with NH_3 to methyl orange, and the lecithin phosphate pptd. in the cold in a vol. of 60 cc. with 5 cc. of 1.5% strychnine nitrate soln. and 15 cc. of a mixt. of 33 33 g. of NH_4 molybdate in 100 cc. of H_2O and 300 cc. of dil. HNO_3 contg. 200 cc. of acid, sp. gr. 1.4. After 20 min the ppt. is filtered off on a weighed crucible, washed with 25 cc. of the ice-cold mixed reagents (dild. 5-fold), and with ice water until free from acid. The wt. of the ppt. dried at 100° and divided by 39 gives P_2O_5. The method has an accuracy of 0.02 mg. for 0.5–4.0 mg. of P_2O_5. The contents of H_2O, cholesterol and lecithin are tabulated for 21 samples of pastry products contg. eggs. A table is given for the calcn. of egg content of a sample from the cholesterol content, 58.7 and 71.4 mg. per 100 g. of ordinary and hard pastry, resp., corresponding with 1 egg per 500 g. of flour, and 151.5 and 164.2 mg., resp., for 3 eggs. Storage of samples for a year with the exception of a few home baked pastries showed no loss of lecithin or cholesterol. The free lecithin content of egg products or pastries is not a reliable means of detg. the freshness of the product. C. R. Fellers

The determination of the concentration of oxidizing agents by means of the residual current. G. Tammann and H. Thiele. *Arch. ges. Physiol.* (*Pflügers*) **226**, 694–6(1931). —An attempt was made to devise a method for detg. the concn. of oxidizing agents in biol. materials from the residual current, i, as defined in Nernst's equation: $i = (D.o.n.F/\delta).c$. In this equation D is the diffusion coeff. of the depolarizer, n is the electrochem. valence of the oxidizing agent, F the electrochem. equiv., o the surface area of the electrode, c the concn. of the oxidizing agent and δ the thickness of the diffusion layer at the cathode. With platinized Pt electrodes roughly approximate results were obtainable for the concn. of H_2O_2 in aq. solns. The residual current for oxygenated blood was 0.002 amp. as compared to 0.0001 amp. for venous blood. A. G.

The determination of the freezing points of small quantities of fluids by means of thermal elements. Experiments with turtle blood. T. Minosima. *Arch. ges. Physiol.* (*Pflügers*) **226**, 794–8(1931).—The f. ps. of 0.5 to 1 cc. quantities of fluids were detd. with an accuracy of ±2% by the use of *constantan-iron* thermoelements and a sensitive elec. arrangement for measuring small p. ds. The method is particularly applicable to biol. fluids when only small quantities of material are available. Arthur Grollman

Influence of formol on the precipitation of serum proteins. Marcel Mascre and Maurice Herbain. *Bull. soc. chim. biol.* **12**, 978–93(1930); cf. *C. A.* **24**, 5052.—Formol affects the pptn. of proteins both by forming formol proteins and by increasing the acidity of nonprotein matter present. The latter factor is responsible for the greater effect upon pptn. by alc. acetone and salts than by CCl_3COOH. The effect is more marked at lower temps. Pptn. with CCl_3COOH includes peptides, and pptn. of serum globulin with Na and Mn sulfate includes much of the albumin. C. G. King

The use of copper and iron salts for the deproteinization of blood. Michael Somogyi. *J. Biol. Chem.* **90**, 725–9(1931); cf. *C. A* **24**, 3808.—Fe salts can be used instead of colloidal $Fe(OH)_3$ for the removal of blood proteins in the detn. of true sugar. Cu salts are preferable to Fe salts for this purpose and fully the equal of Zn salts in regard to speed and simplicity of technic. For the pptn. of plasma or serum proteins Cu is superior to Zn. The technic is described in detail. A. P. Lothrop

The optimum conditions for the precipitation of casein from human and from cow milk. Chi Che Wang and Agnes A. Wood. *Am. J. Diseases Children* **40**, 787–90 (1930).—A clear, edible whey can be prepd. from human milk by treating 100 cc. of fat-free milk with 33 mg. of rennin suspended in 1 cc. of 1 *N* HCl for 15–30 min. at 38°, removing the curd by centrifugation and filtering the supernatant liquid. The max. pptn. of casein from human milk by the action of rennin (and HCl) occurs at p_H 4.97 and represents 50% of the total N of the whole milk. The max. pptn. of cow milk by lactic acid occurs at p_H 4.61, representing 80% of the total N. The max. pptn. by rennin (and HCl) occurs at p_H 6.53, representing 73% of the total N. E. R. Main

The determination of lead in feces and urine and its significance for the diagnosis of lead poisoning. FRITZ FRETWURST AND ARTUR HERTZ. *Arch. Hyg.* **104**, 315–25 (1930).—A method is described for the detn. of Pb in feces and urine by which 0.01 mg. of Pb may be detd. The samples are ashed with HNO_3, the Pb is pptd. first as PbS and finally as $PbCrO_4$, and the latter dissolved in HNO_3 and titrated with $Na_2S_2O_3$. The av. values for normal persons who have not worked with Pb are 0.05 mg. Pb per 100 g. of feces and 0.03 mg. per l. of urine; for persons who have worked with Pb but show no symptoms of poisoning, 0.06 mg. per 100 g. of feces and 0.08 mg. per l. of urine; for persons who have worked with Pb and have symptoms of poisoning 0.2 mg. per 100 g. of feces and 0.07 mg. per l. of urine. E. R. MAIN

The determination of the p_H of phosphate buffer solutions by means of the antimony–antimony oxide electrode. RUSSEL J. FOSBINDER. *J. Lab. Clin. Med.* **16**, 411–4 (1931).—The Sb-SbO electrode gives a linear relation between observed e. m. f. and p_H values. The p_H of phosphate buffer solns. can be detd. with an accuracy of ± 0.01 p_H. The electrode is not applicable to the detn. of the p_H of blood plasma. E. R. MAIN

Chart for computation of daily basal metabolism and percentile basal metabolic rate from spirometer data. CURTIS BRUEN. *J. Lab. Clin. Med.* **16**, 415–8(1931); cf. *C. A.* **24**, 3028.—A nomogram-like chart is presented by which the daily basal metabolism and the percentile basal metabolic rate may be computed from the observed values for vol. decrement of O per min., the av. spirometer temp. and atm. pressure. E. R. MAIN

The determination of silver in organs and in organic liquids. E. MENEGHETTI *Boll. soc. ital. biol. sper.* **5**, 813–4(1930).—The organs or liquids are dried and ashed with Na_2CO_3 in a crucible. Complete ashing is obtained by repeated addns. of small amts. of KNO_3. Concd. HNO_3 is added and evapd. to dryness. For qual. tests, the residue is digested with NH_4OH, filtered and the filtrate is tested for Ag (pptn. of Ag_2S with H_2S, AgCl with HNO_3). For the detn. H_2O is added and then the soln is treated with H_2S for 5 min. and centrifuged; the ppt. is washed carefully 3 times with H_2S water and centrifuged each time. Concd. HNO_3 is then added to the ppt. and brought to dryness on the water bath. The residue is dissolved in H_2O (up to this point the operations are all made in the original crucible), filtered and the ppt. on the filter washed repeatedly with H_2O. To the filtrate in the dark is then added with caution dil HCl until complete pptn. of the chloride. The ppt. is allowed to settle and collected on a Gooch crucible, the ppt. being washed first with cold H_2O contg. a small amt. of HNO_3 until the washings are free of chlorides and then twice with alc. It is dried at 100°, then at 130° to const. wt. (all the later operations are carried out as much as possible away from the light). PETER MASUCCI

Electroultrafiltration, a method for the determination of the physical state of the inorganic constituents of the serum. RUDOLF SPIEGLER. *Biochem. Z.* **230**, 253–8 (1931).—An app. is described for carrying out ultrafiltration with and without electrodialysis. S. MORGULIS

New substrates for use in detecting proteolytic activity. ROBERT L. JONES. *Ind. Eng. Chem., Anal. Ed.* **3**, 149–51(1931).—With a modified method for the prepn. of adsorption systems of egg albumin and dyes a number of reagents can be prepd. which can be used for the detection of proteolytic activity. Two reagents, *egg albumin-iodoeosin* and *egg albumin-basic fuchsin*, give good results with com. pepsin, trypsin and artificial gastric and pancreatic juices. The prepn. of these reagents is easier than that of previous ones. They can be prepd. in powder form and are stable indefinitely. H. T.

A study of glutathione. HAROLD L. MASON. *J. Biol. Chem.* **90**, 409–16(1931); cf. *C. A.* **25**, 719.—The oxidized form of glutathione prepd. by aeration at p_H 7.6, or by treatment with I_2 or $K_3Fe(CN)_6$, followed by isolation from alcoholic soln., gives low analyses, as found by Hopkins (*C. A.* **23**, 5477). This is due to the presence in close combination of 2 mols. EtOH, which can only be removed with great difficulty. Heating at 110–20° *in vacuo* leads to loss in wt. but is accompanied by a reduction in the no. of CO_2H and NH_2 groups. The aeration method gives a quant. yield of the oxidized form and is a convenient procedure for its prepn. K. V. THIMANN

Photometric determination of the cholesterol in the serum. E. BRILL AND GUSTAV HOPF. *Münch. med. Wochschr.* **77**, 142–4(1930).—Heilmeyer first used the step photometer, which was designed for the detn. of color in the textile industry and for the detn. of cholesterol. In order to obtain an easier standardization of both halves of the field and to obtain an idea of the light absorption within the various spectral regions, color filters are introduced into the photometer. These are of 2 types: (1) 3 filters, red, green and blue, which have a relatively wide penetrable area and (2) a larger no. of color filters which allow very definite, narrowly limited, regions of wave length to

pass. By this app. it is possible to det. the amt. of rays absorbed by a color soln. within the spectral region detd. by the various color filters. From this one can det. the corresponding color value of the soln. Results differed as much as 20% when checked with the Windau method. The colorometric method gave the same results indicating that other cholesterol-like substances give a color reaction. R. C. WILLSON

Determination of Ca, Mg and P in cattle excreta (MORRIS, *et al.*) 7. Device for regulating the quantity and compositions of gas mixtures used for anesthesia (U. S. pat. 1,793,608) 1.

C—BACTERIOLOGY

CHARLES B. MORREY

The bactericidal power of viosterol. B. E. MONTGOMERY. *Proc. Soc. Exptl. Biol. Med.* **28**, 481(1930).—Irradiated ergosterol in corn oil neither modified the cultural characteristics nor inhibited the growth of *Bacillus coli* and of *Staphylococcus aureus*. C. V. BAILEY

The present state of chemical study of the tubercle bacillus. ERWIN CHARGAFF. *Naturwissenschaften* **19**, 202-6(1931).—A review of recent work (cf. Anderson and C., *C. A.* **24**, 878, 1134; **25**, 128; Sabin, Doan and Forkner, *Am. Rev. Tuberculosis* **21**, 290(1930)(cf. *C. A.* **25**, 541); Doan, *Proc. Soc. Exptl. Biol. Med.* **26**, 672(1929)) with numerous references. B. J. C. VAN DER HOEVEN

Fluoroscopic examination of certain actinomycetes. FRANZ CORTESE. *Boll. soc. ital. biol. sper.* **5**, 842-4(1930).—The influence of anaerobiosis, p_H of culture media and chem. constitution of the media on fluorescence was studied. The fluorescent substance was extd. from the media by weak alc. and purified by shaking with acidified ether. It is an amorphous, odorless, reddish brown material, sol. in alkalies, pyridine, EtOH, MeOH, acetoacetic acid, acidified Et_2O and concd. inorg acids, slightly sol. in weak inorg. acids or acetone; insol. in H_2O or glycerine, benzene and other fat solvents. In 25% NH_3 it shows 4 absorption bands λ = 630-614, 588-576, 560-536, 518-492. The substance is a pigment belonging to the group of porphyrins. Fluoroscopic examn. showed that *A. albus* and *A. sulphureus* Gasperini are different species of *A. bovis* Harz. PETER MASUCCI.

Destruction of sugar in the intestine by the coli group of bacilli. The etiology of pernicious anemia. KOLOMANN V. KNORR. *Folia Hematol.* **43**, 32-94(1930).—An organism called *Diplococcus anemiae perniciosae* is described and found present in the mouth and duodenal contents of cases of pernicious anemia. *B. coli* plays a secondary role by splitting carbohydrates and proteins, producing especially compds. with the NH-OH group. This aids the toxin produced by the diplococcus. JOHN T. MYERS

Toxin production and properties of bacillus Preisz-Nocard. ABEL ROTTGARDT. *Zentr. Bakt. Parasitenk.*, 1 Abt., **119**, 323-33(1931).—The toxin can be pptd. by $(NH_4)_2SO_4$ and dried *in vacuo* over H_2SO_4. Heat destroys it but the dried toxin is more stable than liquid. Cold preserved either liquid or dried toxin. The same is true of the organisms or endotoxin. Air and light have little effect on the exotoxin. Filtration of exotoxin decreases its toxicity about 50%. Toxin concd. at 45° loses a major part of its toxicity but retains its antigenic power. Toluene, ether or mixts. of them have no effect. At a temp. of zero, 5% phenol has no harmful effect. Formalin weakens the toxin, its effect increasing with temp. The pus-producing power of the toxin is independent of its toxicity. JOHN T. MYERS

Method for preparing photographs of Petri dish cultures by direct contact printing on photographic paper. J. T. BUCHHOLZ AND I. M. LEWIS. *J. Bact.* **19**, 105(1930).—The Petri dishes are used in the same manner as negatives and the resulting prints are positives in natural size, the colonies appearing as white objects on a black background. The process is carried out in a dark room, the source of printing light being a 150-w. Mazda lamp at 3 m. from the object, centered directly above the exposing table to avoid cast shadows. The dish, with cover removed, is pressed bottom down upon the sensitized surface of the paper, and exposed. Color and transparency of the agar, its depth in the dish, type of paper, the developer and its temp. influence the time of exposure required. L. G. PERAGALLO

Resistance of trypanosomes to arseno compounds. M. ADANT. *Compt. rend. soc. biol.* **106**, 57-8(1931).—*Tryp. pecaudi* in mice are not rendered resistant to tryparsamide by a prolonged or even double contact with tryparsamide complex obtained from the liver of mice, which complex, however, according to Levaditi, would be the trypanocide elaborated by the organism following the injection of drugs such as atoxyl or tryparsamide. ALBERT L. RAWLINS

Existence of a specific carbohydrate substance in B. perfringens. MARIE E. JIMENEZ. *Compt. rend. soc. biol.* 106, 140–1(1931).—The precipitogen of *B. perfringens* in salt water or broth is pptd. by addn. of alc. contg. 1.3% Na acetate; a white, gelatinous sediment is obtained which, on drying in vacuum, yields a yellowish powder almost entirely sol. in water; the aq. soln. of this powder ppts. strongly in the presence of the serum obtained in the immunization of horses by means of *B. perfringens;* it does not give the biuret reaction, contains a carbohydrate (Molisch reaction pos.), does not reduce Fehling's soln. except after boiling for 1 hr. with 0.5% H_2SO_4, and it contains N.

ALBERT L. RAWLINS

Brucella abortus in Porto Rico. PABLO MORALES-OTERO. *Porto Rico J. Pub. Health Trop. Med.* 6, 1–88(1930).—Sunlight has a deleterious action on cultures of *Brucella abortus*, since cultures exposed to sunlight were sterile in 3 hrs. Ultra-violet light from an Alpine sun lamp had a similar effect. The temp. was kept low by exposing the cultures on ice; when the temp. was allowed to rise the destructive effect of light was even more pronounced. In studying the influence of heat alone on the cultures it was found that a marked diminution of viable organisms occurred in suspensions of *B. abortus* when incubated in the water bath at 42°, but the suspensions were not sterile after 3 hrs. Organisms which survived the exposure to sunlight and ultra-violet light were cultured in broth and injected into mice to test their virulence. The virulence was altered very little if any by the exposure to light. Vaccination with living vaccines as a method for control of Bang's disease was studied; it is believed that this method deserves further investigation. The glucose utilization, the liberation of H_2S and the growth in Huddleson's dye media were studied on 8 strains of *Brucella* and differences were noted. The serological relations of these strains were examd., but with the exception of 2 they could not be differentiated by agglutination or agglutinin absorption. A striking similarity was found between some of the strains isolated from human beings and some of the porcine strains in their action toward CO_2, their glucose metabolism and the pathol. lesions produced by them in guinea pigs. *B. abortus* seems to be capable of going through a Berkefeld W. filter. Sterile filtrates of a broth culture of *Brucella* when injected into mice did not affect them and produced no appreciable pathological lesions in their viscera. Human infection is very low in Porto Rico despite the high cattle infection. Exptl. infection with *B. abortus* in man suggests that the porcine strains are more virulent for man than are the bovine varieties. Only the most virulent bovine strains can infect man through the gastro-intestinal tract. Smaller doses are necessary to produce infection through abraded skin than through the gastro-intestinal canal. Numerous tables, graphs and references are given. G. SCHWOCH

THOMAS G. PHILLIPS

Synthetic nutrient solutions for culturing Ustilago zeae. EMERY R. RANKER. *J. Agr. Research* 41, 435–43(1930).—A standard reproducible culture medium is recommended for culturing *Ustilago zeae*. This is a synthetic nutrient soln. which has the following compn., expressed as g./l. of soln.: 0.3 g. K_2SO_4, 0.1 g. NH_4NO_3, 0.1 g. $CaCl_2$, 0.1 g. $Mg_3(PO_4)_2 \cdot 4H_2O$, 10 g. dextrose and enough distd. H_2O to make up to 1 l. The reaction of this nutrient soln. before sterilization is p_H 7.4 and after sterilization it is p_H 5.6. The optimum quantity of dextrose varies from 5 to 10 g./l. depending upon the length of time the culture is inoculated. Maltose is preferable to dextrose for certain physiologic forms of smut. When a solid medium is desired 1.5% of agar can be added.

J. R. ADAMS

Seasonal changes in the catalase activity of conifer leaves. JOSEPH DOYLE AND P. O'CONNOR. *Ann. Botany* 44, 907–15(1930).—In confirmation of the results of Doyle and Clinch (cf. *C. A.* 23, 2459) and contrary to the statements of Burge (*C. A.* 20, 2691, 3300) the authors find that the catalase activity of leaves of *Tsuga albertiana, T. canadensis, Juniperus communis, J. rigida, Pinus laricio, P. strobus, P. contorta, Abies webbiana, J. rigida* and *Picea omorica* is in all cases very markedly higher in winter (January) than in May, July or October. Increase in temp. of the plants for short periods during the winter did not alter the catalase activity. In conifers there is no correlation between catalase content and degree of metabolic activity. J. S. C.

The effect of ionized air on the rate of respiration of fungi. S. R. VAN ASPEREN DE BOER. *Ann. Botany* 44, 989–99(1930).—Expts. with *Phycomyces blakesleeanus* and

Polyporus destructor by the Pfeffer-Pettenkofer method and by a microrespirometer method gave consistently neg. effects upon respiration rate. Ionization of the air was effected by means of Po, the degree of ionization ranging from 200 times to several million times that of normal air. JOSEPH S. CALDWELL

The resistance to poisons of desiccated plant tissue. WALTER W. ALLEN. *Ann. Botany* **44**, 1001–9(1930).—Air-dried material of *Mnium hornum* submerged in abs. alc. for 1 to 13 hrs. was able to grow when thoroughly washed and again placed in the soil. Material placed in abs. alc. 1 hr., then in xylene 1 hr., then washed in alc. and in water, also grew, as did material similarly treated with alc. and acetone or alc. and ether. Submersion in dil. (50%) alc. or in chloroform was fatal. JOSEPH S. CALDWELL

Further studies on transport in the cotton plant. I. Preliminary observations on the transport of phosphorus, potassium and calcium. F. G. MASON AND E. G. MASKELL. *Ann. Botany* **45**, 125–73(1931).—The ringing methods employed in earlier studies of the transport of carbohydrates and N were used (*C. A.* **24**, 5331). In plants deprived of a ring of bark, P, K and Ca accumulate above the ring and diminish below it just as do carbohydrates and N. P, K, Ca and ash constituents ascend the stem mainly by way of the wood, and P and K are returned by way of the phloem to the roots. No evidence of the return of Ca from the leaves was obtained. There is evidence that N, K and P may be transported to the lower portion of the plant in amts. in excess of the needs there, and may there pass into the tracheal sap and again be transported to the leaves. This downward movement of mineral nutrients must affect the rate of entrance of the salts and may in part explain the absence of a marked increase in salt uptake when transpiration is increased. It was possible to reverse the direction of movement of P and of ash constituents by reversing the relative positions of the leafy and leafless portions of the stem. Removal of bolls is followed by marked increases in concn. of P and ash and smaller increases in Ca in the stem and leaves. P, K and some ash constituents travel to the boll along gradients in the phloem, Ca mainly through the xylem. J. S. C.

The effect of chloroform upon the rotation in the internodes of Nitella. SUSAN P. NICHOLS. *Bull. Torrey Bot. Club* **57**, 153–63(1930).—In continuation of earlier work upon the effect of wounding upon the rotation of protoplasm (*C. A.* **20**, 433) chloroform has been applied to the wall of an internode with a capillary pipet. An area of non-motile protoplasm is produced at the point of application, over which the general protoplasm pushes as rotation continues. The non-motile area ultimately resumes movement. Dipping the internode into chloroform for 2–5 seconds always resulted in cessation of movement after 3–6 hrs. The effect of chloroform is considered to be one of gelation. JOSEPH S. CALDWELL

Purification and certain properties of the virus of typical tomato mosaic. P. H. BREWER, H. R. KRAYBILL, R. W. SWANSON AND M. W. GARDNER. *Phytopathology* **20**, 943–50(1930). -A clear, colorless virus suspension was obtained by mincing and pressing affected plants, passing the ext. through the supercentrifuge, discarding the liquid, suspending the residue in distd. water, centrifuging and clearing and decolorizing with slightly acid Al gel. Such a suspension was highly infectious and continued to be so after filtering through a Pasteur-Chamberland F filter or Schleicher and Shull 1½% collodion filter, but was made non infectious by passage through a Pasteur-Chamberland B filter, collodion filters of 3% or more, or atmometer cylinders. The material retained by the filters was infectious. Of 9 suspensions stored at 36–40° F., 4 became somewhat weakened with age and 1 had lost its virulence after 564 days. The virus was inactivated when alkalinized to p_H 7.5–8.5 and reactivated by restoring its acidity. It was not inactivated by acid up to p_H 2.46. Heating to 82–84° for 25 min. or to 88° for a shorter time destroys the virus. In cataphoresis tests, the virus-bearing particles accumulate at the pos. pole. JOSEPH S. CALDWELL

Effect of mineral nutrition on the reaction of wheat varieties to leaf rust. K. D. DOAK. *Phytopathology* **21**, 108–9(1931).—Wheat varieties showing various types of reaction to one physiologic form of *Puccinia triticina* were grown in sand cultures with various degrees of excess and deficiency in N, P and K. N increased susceptibility and P and K decreased it. Excess N induced the development of larger primary uredinia, more abundant secondary uredinia and decreased chlorosis. Excess P increased chlorosis and retarded or prevented development of secondary without affecting primary uredinia. Excess K increased chlorosis and decreased the size of primary uredinia. In varieties of intermediate reaction, excess N increased the no. of infection points, while N deficiency, excess P and excess K decreased it. Deficiency of P or of K decreased chlorosis. JOSEPH S. CALDWELL

Hydrogen sulfide as related to the fungicidal action of sulfur. S. E. Q. MCCALLAN AND FRANK WILCOXON. *Phytopathology* **21**, 113(1931).—H_2S is exceedingly toxic to

fungus spores and is evolved when S is applied to spores or to leaves of plants. Germination of conidia and uredo spores of 8 species of fungi were completely inhibited by concns. of H_2S ranging from 0.2 to 40 mg. per l., the order of sensitivity being identical with that of these fungi to S. Evolution of H_2S has been demonstrated in 19 fungi and 26 higher plants. Spores of *Sclerotinia* and *Glomerella* produce 5 and 15% of their weight of H_2S in 6 hrs. Indications point to the reduction of S on or within the spores and its initiation by glutathione. The presence of glutathione in spores of *Sclerotinia* has been demonstrated. JOSEPH S. CALDWELL

The influence of hydrogen-ion concentration and of sodium bicarbonate and related substances on Penicillium italicum and P. digitatum. RAIMUND H. MARLOTH. *Phytopathology* **21**, 169–98(1931).—Citrus fruits are dipped in a 3% soln. of $NaHCO_3$ prior to packing to prevent decay by blue and green molds (*Penicillium italicum* and *P. digitatum*). An attempt was made to det. whether the action is specific or has a general physiol. basis. The fungi were cultured on modified Duggar's soln. to which an autoclaved aq. orange ext. was added in an app. which permitted daily renewal of the medium. *P. italicum* grew nearly equally well over a p_H range of 2.9 to 6.5; *P. digitatum*, over a range of p_H 3.0 to 6.0. Germination of spores in hanging drop cultures was inhibited at p_H 1.5–2.5, and excellent at 3.0 to 5.3, falling off at p_H 7.0–9.0. The Na ion markedly inhibits germination at concns. of 15,000–20,000 p. p. m.; the K ion does not. Na tetraborate is more toxic to *P. digitatum* and $NaHCO_3$ is more toxic to *P. italicum*. The effect of the wash treatment in preventing decay is due to the fact that the film of salt left upon the fruit forms a satd. solution of Na_2CO_3 about the developing germ tubes which is toxic thereto. JOSEPH S. CALDWELL

Enzyme formation in Penicillium glaucum. I. SAKISABURO WADA. *Acta Schol. Med. Univ. Imp. Kioto* **13**, 128–44(1930).—A study of the relationship between the compn. of the nutrient medium and the enzyme content of *Penicillium glaucum*. When this mold is grown on a protein-free, carbohydrate-free medium (salts and glycerol), it contains desamidases, urease, a glucosamine-splitting enzyme, nuclease, pepsin and trypsin-like enzymes and erepsin. It does not show the relation between the nutrient medium and enzyme content exhibited by bacteria. **II.** *Ibid* 145–57.—In the mold cultivated with the above medium lactase and a glucolytic enzyme were absent but these are also lacking in a carbohydrate-contg. medium. In the culture liquid, a nuclease, pepsin, glycogenase, invertase, a glucosidase, a lipase and a hippuric acid splitting enzyme were present. **III.** *Ibid* 158–61.—A comparison of the enzyme content of the mold when grown on a medium contg. protein and carbohydrate (glucose, meat ext. and peptone) with that above shows that the pepsin, trypsin and lipase content is much decreased when these foodstuffs are absent from the medium. H. J. D., JR.

Chlorophyll formation. KURT NOACK AND WILHELM KIESSLING. *Z. angew. Chem.* **44**, 93–6(1931); cf. *C. A.* **25**, 723.—Protochlorophyll, the precursor of chlorophyll, is present in small amt. in seedlings germinated in the dark but is more easily obtained from the inner membrane of the seed coat of pumpkin seeds. It yields a series of derivs. analogous to those prepd. by Willstatter from chlorophyll. Like chlorophyll it contains 3 carboxyls, one of which is esterified with phytol, another with Me, while the 3rd occurs in lactone or lactam linkage. Removal of Mg by acid treatment yields *protopheophytin* contg. the phytol, Me and lactam groupings of the parent substance. Esterification of this with 30% HCl in MeOH replaces the phytol by Me and esterifies the lactam carboxyl, yielding *protophytochlorin trimethyl ester*, m. 234.5°. The opening of the lactam ring causes a marked change in the spectral behavior of the protopheophytin as shown in the intensity sequence of the absorption bands. Partial sapon. of protopheophytin should yield protopheophorbide, but this method is unsatisfactory because the concn. of alkali required leads to anhydridization. *Protopheophorbide* was obtained, however, by partial sapon. of the above trimethyl ester. The substance contains 1 CO_2H, 1 CO_2Me and the lactam group, and is analogous to pheophorbide a. The dimethyl ester, *methylprotopheophorbide*, in which the lactam group remains intact, is best prepd. by reduction of methylpheophorbide a from chlorophyll by means of Fe and 80% CH_2O_2. Its spectrum is midway between that of protopheophytin and that of phylloerythrin. Both protopheophorbide and its Me deriv. yield the same trimethyl ester identical with that obtained from protopheophytin. Derivs. of the protochlorophyll series differ from the corresponding chlorophyll derivs. in that they contain 1 less O. This O, which is a structural part of the chlorophyll, is present in a linkage as yet undetd. Phylloerythrin, the chlorophyll deriv. present in beef bile, is closely related to protopheophytin. Like the latter it yields a green pigment when Mg is introduced by the Grignard reaction with *p*-$Me_2NC_6H_4MgI$. The pigment thus obtained resembles protochlorophyll spectroscopically in the same manner that phylloerythrin resembles proto

pheophytin, *i. e.*, in a displacement of the absorption bands toward the violet. Derivs. of the phylloerythrin series are isomeric with the corresponding protopheophytin derivs. The phylloerythrin used in this work was prepd. from 900 l. of beef bile. It is neither an ester nor a free acid but an intramolecular anhydride, and may be converted into an acid by treatment in the cold with KOH in Me_2CHOH. The accompanying spectral change is similar to that observed in the conversion of protopheophytin to the protophytochlorin trimethyl ester. The product is probably a tricarboxylic acid in which 1 CO_2H is anhydridized. With CH_2N_2 it yields a *trimethyl ester*, m. 232–3°, isomeric with the trimethyl ester of protophytochlorin. Phylloerythrin, like protochlorophyll, is a reduction product of chlorophyll. It gives a secondary series of derivs. in which a splitting off of CO_2 has occurred. Esterification of phylloerythrin with MeOH-HCl yields a mono- or a mixt. of mono- and di-esters according to the intensity of action. Sapon. of the ester gives a tricarboxylic acid contg. 1 Me, and this when esterified yields a *trimethyl ester*, m. 205°. Phylloerythrin thus contains an acid anhydride and a lactam group, the latter probably identical with that of chlorophyll. Chlorophyll formation represents a photooxidation of protochlorophyll. The addn. of O yields chlorophyll a, which in turn is the precursor of the more highly oxidized chlorophyll b. Phylloerythrin formation is the reverse process and consists not only in reduction, but also in Mg cleavage, sapon. and anhydridization. Probably phylloerythrin is a biol. transitional stage between leaf and blood pigment. A. W. Dox

The copper and manganese content of some vegetable tissues. Maria van Leeuwen. *Ann. physiol. physicochim. biol.* **6**, 178–81(1930).—Cu and Mn are present in approx. the same concn. (0.2–2.5 mg. %, averaging around 1) in the leaves of rhododendron, nasturtium, ivy, vine, hops, poplar, fir, etc. H. Eagle

Saponin from spinach. O. Dafert. *Z. Untersuch. Lebensm.* **60**, 408–9(1930).—Very little saponin occurs in the stem or leaf, and none at all in the seed of spinach. The hemolytic index of the root, because of its saponin content, is 1:1000 for sun-dried roots, and 1:400 for roots dried in an oven at 100°. The index rises from 1:85 for a plant 3 weeks old to a max. of 1:800 after 7 weeks, and then falls to 1:280 after 20 weeks. The saponin is extd. from the scraped and sun-dried root in a 5-fold vol. of 70% EtOH for 2 hrs., followed by extn. for 1 hr. with a 2-fold vol. of EtOH. The exts. are filtered, the residue is pressed and the crude saponin then separates from the filtrate after 1 day in the ice-chest. It is filtered off, washed with abs. alc., the filtrate evapd. to $^1/_3$ its vol., cooled and an addnl. yield of saponin is thus obtained. The total quantity is dried, extd. with EtOAc, and the saponin recrystd. from hot 96% EtOH as pointed white needles with a hemolytic index of 1:1,000,000 and m. 260 2°. The properties of saponin are given. Hydrolysis with H_2SO_4 in 50% EtOH, and treatment with charcoal gave a white amorphous *sapogenin*, $C_{24}H_{44}O_7$, m. 208–12°, sol. in alc. and EtOAc and insol. in H_2O, C_6H_6 or Et_2O. C. R. Fellers

Vegetable rennet. D. Milne. *Rept. Operations Dept. Agr., Punjab, Year ending June 30, 1929*, Pt. I, 48–9(1930).—The ripe berries of *Withania coagulans*, which grows wild on the Punjab plains, yields an ext. which is rich in rennet. The crude ext. imparts a brown coloration and a bitter taste to milk and is unsuitable for use in the prepn. of cheese. By repeated pptn. the active principle is obtained free from these objections and in a very pure condition, one part of the prepn. being sufficient to coagulate 1000 parts of milk in 1 min. K. D. Jacob

Decomposition of salts of organic acids by the mold fungus Aspergillus fumaricus. W. Thies. *Ber.* **64B**, 214–8(1931).—*Aspergillus fumaricus* decomposes sugar, forming not only H_2CO_3 and $H_2C_2O_4$ as end products, but also citric (I), fumaric (II) and gluconic (III) acids. If other acids are formed as intermediate products, the fungus should decomposes these acids in sugar-free cultures to I or II. Two series of expts. were carried out, one with the Ca salts of I, II and III, and of saccharic, succinic, tartaric, malic and lactic acids, the other with the K, Na and NH_4 salts of the same acids. I and II were included in order to det. whether they are exclusively end products, or whether they are further utilizable by the fungus. In the first series H_2CO_3 was the end product of the decompn., as shown by the formation of considerable quantities of $CaCO_3$; in the second, the end product was $H_2C_2O_4$. The results indicate that the nature of the cation affects the change: if the cation is bivalent, the end product is H_2CO_3; if univalent, the end product is $H_2C_2O_4$. The expts. show clearly that there is no support for the theory that in the decompn. of sugar to I or II, other acids are formed as intermediate products. Louise Kelley

The influence of environmental factors on acid formation by Aspergillus fumaricus. W. Thies. *Zentr. Bakt. Parasitenk.*, 2 Abt., **82**, 321–47(1930); cf. preceding abstract.—The influence of various factors as, neutralization with Pb or $BaCO_3$, O tension, character of the medium and p_H, had little influence on acid production. Gluconic and citric

acids are always formed; oxalic and fumaric acids sometimes result. Other acids are not formed. JOHN T. MYERS

Presence of rutoside in the leafy stems of Bupleorum falcatum L. J. RABATE. *Bull. soc. chim. biol.* **12**, 974–7(1930).—Extn. with alc. gave 4.3 g. per kg. dry wt. C. G. KING

Wall structure and mineralization in coralline algae. L. G. M. BAAS-BECKING AND E. WAYNE GALLIHER. *J. Phys. Chem.* **35**, 467–79(1931).—The optical properties of the cell walls of the algae, *Corallina officinalis* Lamark and *Amphiroa dorbigniana* Decaisne were studied in the hopes of detg. their chem. and phys. nature. The data show that the cell walls of these 2 organisms are made of a non-cellulosic material, probably a pectin-like substance, and are birefringent in longitudinal and isotropic in cross section. The fibers are built up of tangentially arranged, elongate lamellae interspersed with concentrically arranged interstices, both of which are small in relation to the wave length of light. Calcite is the only mineral deposited by the living organism, the individual crystals of which are only a few tenths of a micron long, and arranged with the c-axis perpendicular to the longitudinal axis of the fiber. The deposition of Mg is a secondary phenomenon. H. W. LEAHY

Investigations on the nutrition of fruit trees. Some effects of deficiencies of nitrogen, potassium, calcium and magnesium, with special reference to the behavior of certain varieties of apple trees. M. B. DAVIS. *J. Pomology and Hort. Sci.* **8**, 316–44 (1930).—Bramley seedling, Worcester Permain and Allington Pippin apples were grown under controlled conditions in pots in sand and in soil and given differential nutritional treatments. Omission of N resulted in restricted shoot growth, yellowed leaves and delayed bud break in spring. Lack of K_2O caused early partial defoliation and later retention of the remaining foliage, leaf scorch and much earlier bud break. P_2O_5 omission produced earlier defoliation, very restricted shoot growth, typical bronzing of the foliage and delayed bud break. Absence of CaO resulted in increased shoot growth and larger leaves, which later broke down either in the center or along the margins. Omission of MgO was characterized by reduced shoot growth in most cases, earlier defoliation and marked breakdown of foliage as brown spots in the center and margins of the leaves. The omission of an element always resulted in a lower percentage of that element in the ash and dry matter of the young shoots and leaves. Reduction of K_2O was assocd. with increases of CaO and MgO; low CaO was accompanied by high K_2O, high MgO and low P_2O_5; low MgO was assocd. with high CaO, low P_2O_5 and low K_2O. A high degree of correlation existed between symptoms exhibited and amt. of the related element in the ash and dry matter. A. L. MEHRING

Prolonging the longevity of rice seed. G. SAMPIETRO. *Giorn. risicoltura* **21**, 1–5 (1931).—Rice seed, dried to a moisture content of 5% and kept in an atm. of N, gave a 99% germination after 8 years. Seed kept in CO_2, in vacuum or in air did not germinate at all when dried to a normal 13% or to a 5% moisture content; likewise seed kept in N when contg. 13% moisture. ALBERT R. MERZ

The influence of iodine on the reproduction of yeasts. J. KOOIJMANS. *Zentr. Bakt. Parasitenk.*, 2 Abt., **82**, 347–53(1930).—Minute amts. of I (about one ten millionth part) have a slight growth-stimulating effect on some strains of yeast. There is no relationship between I and bios. JOHN T. MYERS

The pigment of the watermelon. L. ZECHMEISTER AND P. TUZSON. *Ber.* **63B**, 2881–3(1930).—The pigment consists of a mixt. of lycopin and carotene (8–10 parts of the former to 1 of the latter in melons from southern Hungary). In small-scale expts. 0.2 g. of the mixt. was obtained from fourteen kilograms of the fresh melons, while 150 kg. of the melons yielded 1.3 g. lycopin and 0.07 g. carotene, and another 0.07 g. of the latter remained in the mother liquors. C. A. R.

Permeability of I on some economic plants (MALHOTRA) **15**. Salicinercin of *Salix cinerea* L.; its identity with piceoside (RABATE) **10**.

E—NUTRITION

PHILIP B. HAWK

Animal experiments on the significance of increased vitamin administration in the therapy of tuberculosis. W. PFANNSTIEL AND B. SCHARLAU. *Beitr. klin. Tuberk.* **73**, 351–72(1930).—The authors used not only primary infected animals but also superinfected immune animals which had been given the preliminary infection with low virulent human tubercle bacilli. In rabbits vitamin B concentrate contg. in 1 cc. the equiv. of 100 g. of yeast, and vitamin D (ergosterol, vigantol) revealed no therapeutic effect. Vitamin A (cod liver oil), however, had a favorable influence on some of the animals.

Therapeutic action was noted with a coincident peroral administration of yeast and rayed ergosterol. With weak infections in immune animals there was a complete lack of tuberculosis following the use of vitamins B and D, while with larger infection there occurred a favorable type of disease. A similar, though smaller, effect was noted in primary infected animals. A decidedly less effect resulted when vigantol soln. was not given perorally but by inhalation. Primary infected animals were unfavorably affected by overdoses of vitamins B, D and A. In children wt. control can prevent overdosing of vitamin D, and the danger of a B hypervitaminosis need not be feared. H. J. C.

Vitamin A and carotene. NORMAN S. CAPPER. *Nature* **126**, 685(1930).—The administration of 1 mg. doses of carotene daily to chickens on a vitamin-A-free diet cured the vitamin-A deficiency and enabled normal growth to take place. The livers of these birds gave strong positive tests for vitamin A. It is concluded that carotene may serve as a precursor of this vitamin. H. J. DEUEL, JR.

The significance of the ultra-red range for the protective substance against rickets. WALTER HIRSCH AND LOTTE KELLNER. *Klin. Wochschr.* **10**, 171–2(1931).—Ergosterol, has an absorption band at 3.7μ (ultra-red); following irradiation with ultra-violet light the ergosterol develops a new weak absorption band at 0.97μ, while the normal band increases in intensity. Ergosterol, irradiated with ultra-violet light, has 2 absorption ranges in the ultra-violet range at 260–300 and 230–260 mμ. Both are increased by subsequent ultra-red irradiation; in the case of the former, the increase signifies a decompn. of the sp. protective substance; in the latter it signifies the formation of a new substance. The antirachitic factor of ergosterol irradiated with ultra-violet light is destroyed by the ultra-red. H. EAGLE

Importance of sugar as the fuel of life. F. FISCHLER. *Arch. Pharm.* **269**, 9–22 (1931).—An address. W. O. E.

Detection of vitamin A in invalid food products. H. MATTIS AND E. NOLTE. *Arch. Pharm.* **269**, 22–4(1931).—The results obtained with 3 series of rats in an exptl. examn. of the products Novotropon and Ferripan are graphically shown in connection with the keratomalacia induced and later dissipated by feeding with vitamin-A-free products and the above-named invalid foods. W. O. E.

Influence of the canning industry in the changing dietary. E. F. KOHMAN. *J. Am. Dietetic Assoc.* **6**, 123–9(1930).—Canned foods have 3 distinct advantages from the standpoint of their vitamins: (1) they are always canned promptly after harvesting; (2) oxidation, which destroys the vitamins, is not permitted to take place in com. canning as it does in open-kettle cooking and (3) after canning, the vitamins in canned foods are apparently stable and may be stored for long periods with insignificant or no loss. For example, canned tomatoes are richer in vitamins A and B than orange juice and are only slightly lower in vitamin C. Canned fish products of all descriptions contain an unusual amt. of I. The diet, even though complete in its chem. constituents, will not produce its optimum effect unless eaten with relish and enjoyment. C. R. FELLERS

Influence of fertilizer treatment on the vitamin A content of spinach. HANNAH E. HONEYWELL AND R. ADAMS DUTCHER. Penna. Agr. Expt. Sta., *Bull.* **258**, 8(1930); *43d Ann. Report* (Abstract).—Fourteen samples of Rhode Island spinach, dried and stored under CO_2, were assayed for vitamin-A content. The spinach was grown under various fertilizer treatments. No significant results were obtained except that where spinach is grown with Mn as a limiting soil nutrient, less vitamin A is found. This indicates that pigmentation, metabolism and vitamin A synthesis are correlated. The work is being continued. C. R. FELLERS

"Luxury consumption" and feeding. R. BONNET AND T. H. TCHI. *Arch. intern. physiol.* **31**, 335–57(1929); *Physiol. Abstracts* **15**, 243.—In overfeeding, rabbits and pigeons do not make a "luxury consumption," and in underfeeding the breakdown processes of the body are cut down correspondingly G. G.

Physiological ketogenesis in herbivora. P. H. FLEURET. *Arch. intern. physiol.* **31**, 363–412(1929); *Physiol. Abstracts* **15**, 243(1930).—In herbivora there is an abundant excretion of keto bodies on any diet or in inanition; these substances are of both endogenous and exogenous origin. Proteins are more ketogenic than carbohydrates, which are in turn more so than fats. The addn. of HCl to the food diminishes the excretion of "keto bodies," but there is no relation between the excretion and the total acidity or alky. of the urine. Variations occur in any one animal on a const. diet, and also in different animals. G. G.

Mineral feeding experiments. Iodine, lime and salt-lick questions. B. W. SIMPSON. *New Zealand J. Agr.* **42**, 18–23(1931).—The I content of beets and lucerne was increased about 10-fold by the application of small amts. of I salts to the soil. The

percentage increase in the growth of rabbits receiving I either in the form of inorg. salts or in the form of foods high in I was distinctly greater than that of the control animals. Addn. of lime, alone or in the form of salt-lick, to the diet of rabbits did not cause enlargement of the thyroid gland. K. D. JACOB

The vitamin D content of grasses varying in origin and fertilization. ARTHUR SCHEUNERT AND JOHANNES RESCHKE. *Tierernähr.* 2, 262–9(1930).—A no. of green grasses of varying origins were tested for their vitamin-D content. Different types of grass have different vitamin-D contents. The same type of grass may show a widely varying vitamin-D content. The reasons for this cannot be explained. No decisive influence seems to be attributable to the use of artificial fertilizers. The conditions of the soil presumably play the most important part. J. C. JURRJENS

A new cereal mixture containing vitamins and mineral elements. FREDERICK F. TISDALL, T. G. H. DRAKE AND ALAN BROWN. *Am. J. Diseases Children* 40, 791–9 (1930).—The prepn. of a cereal mixt. is described, composed of wheat meal, oat meal, corn meal, wheat germ, bone meal, dried brewer's yeast and alfalfa. The mixt. supplies the minerals and vitamins which are lacking in the ordinary milled, part grain cereal. The Fe content of the mixt. is 0.024%, the Cu content, 0.0013%, and the Ca content, 0.78%. Vitamin A is supplied by the wheat germ and the alfalfa, vitamin B_1 and B_2 by wheat germ and yeast and vitamin E by the wheat germ. Vitamin D may be secured by irradiation either of the wheat germ or the yeast. The mixt. is palatable and does not irritate the intestinal tract. E. R. MAIN

Milk sugar in infant feeding. A study of the effects of the routine use of milk sugar in infant feeding. B. WINSTON JARVIS. *Am. J. Diseases Children* 40, 993–9 (1930).—Lactose given to infants in 10 g. quantities at 3-day intervals is well tolerated when methods are used to give the other elements of the diet their max. digestibility. Infants fed with lactose resemble breast-fed infants in firmness of tissue and resistance to infection. When compared according to age-wt., they possess more living tissue than infants fed on vegetable sugar, and are less susceptible to sudden dehydration with acidosis as a result of parenteral infection. The use of lactose is desirable as a source of galactose for the development of the central nervous system. E. R. MAIN

The carbon dioxide absorption curve of infants fed lactic acid, hydrochloric acid and boiled cow milk. DANIEL C. DARROW. *Am. J. Diseases Children* 40, 1010–23(1930).—The CO_2 absorption curves for children fed either boiled whole milk or milk to which lactic acid, or both lactic acid and HCl have been added are essentially normal. The same changes in diet produce no significant changes in the bicarbonate concn., lactic acid concn. or p_H of the blood. The p_H of the venous blood, in infancy, is 7.37 ± 0.05. The venous CO_2 tension is 41 ± 5.0 mm. of Hg. The hemoglobin exerts the same influence on the slope of the CO_2 absorption curve as in adults. E. R. MAIN

Recent progress in poultry nutrition. GRIGORIJ CHOMKOVIC AND JAN PODHRADSKY. *Wiss. Arch. Landw., Abt. B., Tierernähr. Tierzucht* 2, 27–214(1930).—A review. Seven pages of references are appended. W. GORDON ROSE

Banana—a challenge to chemical investigation (VON LORSECKER) **12.** Vitamins and palm oil in margarine (EPSTEIN) **27.** Determination of Ca, Mg and P in cattle excreta (MORRIS, *et al.*) **7.**

BERG, RAGNAR: **Eiweissbedarf und Mineralstoffwechsel bei einfachster Ernährung.** Leipzig: Hirzel. 239 pp. M. 10.50; linen, M. 12.

F—PHYSIOLOGY

E. K. MARSHALL, JR.

Citric acid content of animal fluids (cerebrospinal, follicular and amniotic fluids and aqueous humor). I. I. NITZESCU AND I. D. GEORGESCU. *Compt. rend.* 190, 1325–7 (1930).—The citric acid content of the following animal fluids has been detd. by Thunberg's methylene-blue test: human cerebrospinal fluid 0.075–0.080 g. per l.; of dogs 0.090–0.100 g. per l.; aq. humor of oxen, 0.012 g. per l.; follicular fluid of cows, 0.040 g. per l.; human amniotic fluid, 0.025–0.027 g. per l. B. C. A.

Occurrence of metallic elements in biological material. W. B. S. BISHOP. *Cancer Research Comm. Univ. of Sydney* 1, 242–53(1930).—The elements of groups I and II in the periodic table are widely distributed. Group III is the poorest as regards biol. occurrence, the presence of Al in animal tissues being much in dispute. Pb (group IV) is the 1st toxic element occurring in tissues. As and V are biologically the most interesting members of group V, the latter being but slowly eliminated after injection. The carcinogenetic action of tar does not depend on its As content. Mn is found in small

amt. in animal tissues but is not related to sarcomata or carcinomata. Cu is connected with hemoglobin formation, while Zn may play some part in reproduction. B. C. A.

Fibrillar structures in the albuminous layer of the egg of the fowl. G. C. HERINGA AND S. H. VAN KEMPE VALK. *Proc. Acad. Sci. Amsterdam* **33**, 530–2(1930).—The albuminous layer surrounding the egg yolk consists of a series of strata, the outer layers being clear and transparent, while the rest is opaque. The membranes are of fibrillar structure. The fibrils are dissolved on digestion with pepsin and HCl at 37°, when the albumin of a hard-boiled egg is dissolved completely. In a raw egg the membranes are dissolved less readily than is the remainder of the albumin, and when sections are prepared from a frozen egg, the membranous structures remain in connection even after digestion. The membranes are completely sol. in alk. trypsin. Evidence is obtained that the fibrils are composed of a keratinic substance. B. C. A.

The absorption of ultra-violet light by the liquids of the organism. J. CLUZET AND T. KOFMAN. *Compt. rend. soc. biol.* **103**, 1123–5(1930).—Serum, plasma, urine, bile and aq. humor (ox) are completely opaque in a layer 15 mm. thick to ultra-violet light (3000–2300 A. U.). Cerebrospinal fluid, however, has an opacity relative to H_2O of 68.6. The opacities of increasing dilns. of these liquids show important differences. The electrolyte contents of bile and urine are responsible for as much absorption of ultra-violet light as the proteins of serum or plasma. The opacity of defibrinated blood at dilns. of 1/100–1/1000 is much greater than that of plasma for the same dilns.

B. C. BRUNSTETTER

Acetylcholine in beef blood. Comment on the paper of J. Kapfhammer and C. Bischoff. FRITZ WREDE AND WERNER KEIL. *Z. physiol. Chem.* **194**, 229–31(1931).—Kapfhammer and Bischoff (*C. A.* **25**, 127) have reported the occurrence of acetylcholine (28.8 mg. per l.) in beef blood, but neglected to verify their findings by physiol. tests on isolated intestine. Exts. prepd. by the method of K. and B. failed to show any physiol. action on guinea pig intestine in Tyrode soln. An ext. which should contain 2.9 mg. acetylcholine per cc. according to K. and B. gave no appreciable contraction with quantities of less than 5 cc. Acetylcholine added to the blood in quantities up to 30 mg. per l. disappeared completely during the process of purification. On the other hand, treatment of acetylcholine-HCl salt with 10% CCl_3CO_2H during 12 hrs. did not impair its physiol. action. It appears that the acetylcholine, originally present or subsequently added, is carried down in the protein pptn., and does not appear in the ext. as claimed by K. and B. A. W. DOX

Choline in the uterus and its relation to labor pains. ERICH STRACK AND ADALBERT LOESCHKE. *Z. physiol. Chem.* **194**, 269–76(1931); cf. *C. A.* **23**, 5493.—Although the human placenta contains 180 mg. of choline per kg. no choline could be found in the gravid uterus. The av. choline content of the non-gravid human uterus was 47 mg. per kg. Beef and pig uteri, on the other hand, showed practically the same choline content in the gravid as in the non-gravid state, approx. 160 mg. No physiol. relationship could be demonstrated between choline content of the uterus and the onset or severity of labor pains. A. W. DOX

Regulation of the secretion of insulin, with observations on the regeneration of the islands of Langerhans in the pancreas. G. JORNS. *Klin. Wochschr.* **8**, 2319–22 (1929).—An inconclusive, highly theoretical discussion. H. EAGLE

The hormones of the anterior lobe of the hypophysis. I. BERNHARD ZONDEK. *Klin. Wochschr.* **9**, 245–8(1930); cf. *C. A.* **23**, 4738.—The hormone of the anterior pituitary lobe is the true sex hormone. An ext. (prolan) injected into the infantile rat causes (1) ripening of follicles, ovulation and rut, (2) the appearance of blood points in the ovary, and (3) formation of corpora lutea. Prolan is not the same as the growth-promoting ext. of Evan; and although it contains prephyson, the substance which regulates the sp. dynamic action of foods (Kestner), its hormonal effects upon the sex glands are not due to this substance. The sex hormone in prolan contains at least 2 distinct substances: one which initiates follicular ripening, uterine hyperemia and mucosal changes in the vagina of infantile white rats 4–5 weeks old (prolan A), and another which causes the formation of corpora lutea in 3–4 weeks old female mice, and which has no effect upon the uterine or vaginal mucosa (prolan B). Folliculin is formed both by the follicles and by copora lutea in women, but only by the former in animals. In the animal prolan A would mobilize folliculin, which induces rut; prolan B would induce luteinization. The formed copora lutea would then induce the hypersecretion of the uterine and vaginal mucosa by their hormone, which Corner calls lutin. **II. Follicular ripening hormone (prolan A). Menopause. Castration.** *Ibid* 393–6.—Prolan A can usually not be demonstrated in the urine of non-pregnant women unless it is concd. more than 5 times before extn. At the onset of climacterium there is an enormous

increase in the excretion of folliculin, up to as high as 200 units per 1000 cc. of morning urine, to be contrasted with the 10 and 30 units normally excreted during the intermenstrual and premenstrual period, resp. There is at this time a polyfolliculin amenorrhea. The second stage begins weeks or months later and is characterized by a complete absence of folliculin from the urine, with accompanying vasomotor disturbances. Finally, there is increased excretion of prolan A, which can be demonstrated in the urine of 25% of women at the menopause. Following removal of both ovaries, prolan A promptly appears in the urine in 75% of the cases. Even after Röntgen-ray castration, it appeared in 4 out of 10 cases. Z. suggests that it is excreted in the urine only when the ovaries, its elective site of action, are removed. Its increased formation following castration may be due to the removal of an ovarian-inhibiting substance. It is significant that the hypophysis undergoes histological changes at the menopause or following castration. H. EAGLE

Energy metabolism and its clinical significance (formation of lactic acid and oxygen consumption, function and metabolism, diet.) S. G. ZONDEK AND F. MATAKAS. *Klin. Wochschr.* 10, 11–7(1931).—The recent evidence tending to show that the formation of lactic acid is not the actual cause of muscle contraction is summarized: (1) Acetylcholine and other substances cause contraction without the release of lactic acid. (2) In tonic contractions, the formation of lactic acid follows the beginning of contraction. (3) Lactic acid production can be entirely inhibited by bromoacetic acid, *e. g.*, the possible *role of phosphocreatine* is discussed. In muscles under tension there are structural and functional changes which may explain the anomalous increase in lactic acid. Similar aerobic glucolysis is observed in other conditions involving nonspecific disturbances in metalbolism (Basedow's disease) as also in the metabolism of old leucocytes and mature erythrocytes. Deviations from the usual course of metabolism, in general, may therefore be due to non-specific cellular injury. Thus, lactic acid is not the cause, but a product, of muscle fatigue. The authors discuss the relation of these problems of muscle metabolism to clinical conditions. H. EAGLE

The relationship of fat in its passage through the placenta (contribution to the physiology of the placenta). WERNER BICKENBACH AND HANS RUPP. *Klin. Wochschr.* 10, 63–4(1931).—The fetus receives its fat directly from the maternal organism, unchanged by its placental passage. Thus, if pregnant rabbits are fed with linseed oil, cóntg. an oil with an I no. of 165–175 (normal rabbit fat = I no. of 50–60), the fat of the fetus is found to have exactly the same I no. as that of the mother. There is no real evidence for a splitting of fat in its passage through the placenta, such as occurs in the intestinal wall. Indeed, if the methyl esters of oleic acid, and the amyl ester of palmitic acid, are injected into a pregnant rabbit intravenously, they can be found as such in the fetal tissue; but no free amyl alc. or MeOH is demonstrable, indicating that there had not been any splitting of the fat in its placental passage. H. EAGLE

Pyroracemic acid in the metabolism of animal cells. BRUNO MENDEL, MILLY BAUCH AND FRIDA STRELITZ. *Klin. Wochschr.* 10, 118–9(1931).—Pyroracemic acid increases anaerobic fermentation by body cells more than 100%, causing them to approximate glucolytic activity of cancer cells. A simple test for pyroracemic acid is described, which is based on the fact that it prevents glyceraldehyde from inhibiting the fermentation by Jensen sarcoma, a test which detects several thousandths of a mg. Using this test, as well as that of Warburg, the authors find that cancer cells under normal conditions form very large quantities of pyroracemic acid. It is also present in mammalian sera: 10 mg. % in the serum of white mice, and somewhat less in rabbit, rat, guinea pig and human serum. H. EAGLE

The solubility, dissociation and tension of carbonic acid in urine. FRITZ MAINZER *Klin. Wochschr.* 10, 119(1931).—The soly. coeff. α (38°) varies between 0.44 and 0.51, the apparent dissocn. const. P (38°) is 5.8 6.3. The tension is very variable, ranging between 16.7 and 242 mm. Hg in 20-odd urines; obviously, however, it is much greater than it can possibly be in the tissues. H. EAGLE

The occurrence of very small quantities of mercury in the urine and stools. Its diagnostic significance and causes. PAUL BORINSKI. *Klin. Wochschr.* 10, 149–53 (1931).—38 of 75 normal people excreted as high as 10γ Hg daily, despite the absence of any known exposure to Hg. People with recent dental amalgam fillings excrete considerably more. Almost all foods contain Hg, the total quantity in the daily intake being about 5γ, corresponding to the urine output. H. EAGLE

Activating split products and hormones of the tissues. WOLFGANG WEICHARDT *Klin. Wochschr.* 10, 153–4(1931). Tissue exts. injected into mice increase the performance of its muscles; in larger doses they cause paralysis. Non-specific toxic processes may cause the liberation of these tissue hormones in the body, as shown by expts. upon

hearts. Very small quantities have no effect upon normal tissues, but do increase the performance of fatigued organs. Thus, 1:20,000 diln. of a hydrolysis product of the skin had a definite effect upon the contraction of a fatigued heart. H. EAGLE

The specific gravity of blood and its constituent parts. C. OESTREICH. *Klin. Wochschr.* **10**, 160–2(1931).—The sp. gr. of whole blood is 1.05–1.06, that of plasma 1.025–1.026. In *pernicious anemia*, the sp. gr. of the erythrocytes proper is increased from a normal value of 1.085–1.094 to 1.095–1.1. H. EAGLE

The time relationship of the formation of lactic acid in muscle contraction. OTTO MEYERHOF. *Klin. Wochschr.* **10**, 214–5(1931).—M. confirms the finding of Lehnartz that the supposed const. K = tension (g.) × duration of tetanus (seconds) × (cm. of muscle length/lactic acid formed (g.)) is larger if the muscle is killed immediately after the tetanic contraction than if 2–5 min. are allowed to elapse, *i. e.*, that there is a post-tetanic formation of lactic acid. However, he is unable to find that the const. K = tension (g.) × muscle length (cm.)/lactic acid (g.) for single contractions is dependent upon the time interval between stimuli, over a wide range (1–10 sec.). This late formation of lactic acid may play an important role in making possible the anaerobic resynthesis of creatinephosphoric acid, which is an endothermic reaction. H. EAGLE

Growth and development with special reference to domestic animals. XVI. The influence of temperature and breeding upon the rate of growth of chick embryos. EARL W. HENDERSON. Missouri Agr. Expt. Sta., *Research Bull.* **149**, 5–47(1930). —Temp. exerts a profound influence on the growth rate of chick embryos as measured by daily dry wt. and N content as indicated by temp. coeffs. This influence is greatest in the earliest stages of growth and it decreases at successive stages and practically ceases when the embryo is about 16 days old or when it reaches a dry wt. of approx. 2 g. Loss of moisture of eggs is slightly increased by an increase in temp. if the relative humidity is const. In general, the limits of the growth periods at 38.8° coincide with the periods marking a change in the type of chem. compd. utilized for energy. C. R. FELLERS

Respiration of the tissues. V. Respiration of blood, in vitro, of various homothermal animals. J. ROCHE AND E. S. SORU. *Arch. intern. physiol.* **31**, 413–27(1929); *Physiol. Abstracts* **15**, 220–1; cf. *C. A.* **21**, 2499.—With the same content of erythrocytes the blood of animals with nucleated red cells has a greater respiratory intensity than that of animals with non-nucleated cells. There is no direct relationship between the oxyhemoglobin content of the blood and the O consumption. If the plasma is replaced by Ringer's soln., the respiratory intensity is diminished. G. G.

Muscular work and glucemia. V. BINCER. *Arch. intern. physiol.* **31**, 428–32 (1929), *Physiol. Abstracts* **15**, 238–9.—In the rabbit, starvation causes an immediate fall in blood sugar, followed by a const. level; intense work after several days' starvation produces a marked but very transient increase of the order of 100 mg. per l. G. G.

A new function of the stomach—its role in the metabolism of urea. R. VLADESCO, D. SIMICI AND M. POPESCO. *Compt. rend.* **192**, 308–10(1931); cf. *C. A.* **24**, 5811.—A 14 kg. dog was anesthetized with chloralose and gastric secretion stimulated by injection of 2 mg. histamine. A sample of the gastric juice showed some NH_3 present but no urea; 45 min. and 90 min. after the intravenous injection of 15 g. urea the gastric juice contained 1.5 and 2.7 times the normal amt. of NH_3 but no urea. When a 3% soln. of urea was kept at 37° *in vitro* in contact with washed dog stomach mucosa the urea was almost completely converted into NH_3 in a few hrs. *Conclusion*.—The normal stomach removes a little urea from the blood and excretes it as NH_3. In times of renal insufficiency this action may be increased 5–10 times in amt. L. E. GILSON

The relation between blood sugar and blood-clotting time. V. Inter-relation between blood sugar, clotting time and glucolysis. A. PARTOS. *Arch. ges. Physiol. (Pflügers)* **226**, 347–53(1930); cf. *C. A.* **24**, 4543.—The hyperglucemia following the administration of adrenaline or morphine is accompanied by an accelerated glucolysis. Insulin administration is accompanied by an inhibited glucolysis. No relation was found to exist between the rate of glucolysis and the clotting time of blood. **VI. The relation of the blood sugar to the lactic acid content during glucolysis.** A. PARTOS AND A. HERZOG. *Ibid* 464–71.—The lactic acid content of blood was always increased at the beginning of glucolysis. No relationship was discovered to exist between the sugar and lactic acid contents of the blood. ARTHUR GROLLMAN

The constancy of the alveolar ventilation and the variations in the alveolar carbon dioxide and oxygen deficit during voluntary variations of the frequency and depth of respiration. HANS HECKSCHER, H. FADDERSBÖLL AND ERIK MOGENSEN. *Arch. ges. Physiol. (Pflügers)* **226**, 418–30(1930). ARTHUR GROLLMAN

The oxygen deficit and carbon dioxide tension of the alveolar air. HANS HECKSCHER. *Arch. ges. Physiol.* (*Pflügers*) **226**, 431–47(1930); cf. *C. A.* **24**, 4090.
ARTHUR GROLLMAN

The chemical composition of the lung: a contribution to the metabolic physiology of the lung. H. MISCHNAT, H. SCHOENEN AND P. JUNKERSDORF. *Arch. ges. Physiol.* (*Pflügers*) **226**, 448–63(1930).—Data are given for the H_2O, glycogen, fat, total N, total P, lipoidal P and Ca contents of dog lungs. The H_2O, glycogen and fat contents of the liver, muscle and heart of the same animals were also detd. The effect of the type of food ingested, glycogen feeding, starvation, phlorhizin, insulin and adrenaline injections, on the chem. compn. of the above-mentioned organs are also given. A. G.

Investigations of the chemical composition of the various lobes of the liver. W. SCHEIFF. *Arch. ges. Physiol.* (*Pflügers*) **226**, 481–99(1931).—The glycogen, fat, total N, rest-N and H_2O contents of the various lobes of the liver differ to an appreciable extent. Various parts of the same lobe also differ as regards their chem. compn. A. G.

The heat formation of skeletal muscle when lactic acid formation is inhibited. ERNST FISCHER. *Arch. ges. Physiol.* (*Pflügers*) **226**, 500–17(1931).—The *caloric quotient* of frog muscles poisoned by $CH_2BrCOOH$ is not altered from the normal. The poisoned muscles fail to show the evolution of an *aerobic recovery heat*. A. G.

The complex nature of the hypophyseal sex hormone: its action on the female. E. DINGEMANSE AND S. E. DE JONGH. *Arch. ges. Physiol.* (*Pflügers*) **226**, 543–6(1931). The sex hormone of the hypophysis consists of at least 2 substances. One factor causes maturation of the *Graafian* follicles; the other causes *lutein* formation. A. G.

The action of the hypophyseal sex hormone on the male organism. S. E. DE JONGH. *Arch. ges. Physiol.* (*Pflügers*) **226**, 547–58(1931).—Young male rats or mice were treated with exts. of *menformone-free* urine. Such exts. contain only the hypophyseal sex hormone. The physiol. action of this hormone was demonstrated
ARTHUR GROLLMAN

The absorption of dyes by the red corpuscles. R. HÖBER AND G. PUPILLI. *Arch. ges. Physiol.* (*Pflügers*) **226**, 585–99(1931).—The distribution of dyes between red blood corpuscles and serum is detd. by the nature of the dyes—particularly its soly. relationships, and by the lipoid content of the corpuscle. ARTHUR GROLLMAN

The action of potassium and calcium ions on the function of the isolated salivary gland supplied with degenerated nerves. O. V. NIKOLAEV. *Arch. ges. Physiol.* (*Pflügers*) **226**, 689–93(1931).—If the $[Ca^{++}]$ of the perfusate through an isolated salivary gland, whose nerve supply is degenerated, is increased, there is an increase in the salivary secretion. An increase in the $[K^+]$ diminishes the secretion. In both cases there is a diminished blood flow through the gland due to vascular constriction.
ARTHUR GROLLMAN

Sleep, sleeplessness and physical exercise and their effect on the blood chemistry. II. The recovery period. H. HOCHREIN, J. MICHELSEN AND H. BECKER. *Arch. ges. Physiol.* (*Pflügers*) **226**, 738–45(1931). —The blood chemistry (lactic acid, O capacity, and p_H) of individuals deprived of sleep differs in the recovery period after exercise from that of normally rested individuals. ARTHUR GROLLMAN

The humoral nature of nervous irritability. I. P. RAZENKOV AND A. N. PCHELINA *Arch. ges. Physiol.* (*Pflügers*) **226**, 786–93(1931). —Stimulation of the vagus leads to the formation of substances in the glandular cells of the stomach and pancreas which act as hormones in the circulation. ARTHUR GROLLMAN

The relation between the hormone of the anterior lobe of the hypophysis (prolan **and the male sex gland.** M. BORST *Deut. med Wochschr.* **56**, 1117–20(1930).—The injection of *prolan*, an ext. of the anterior lobe of the hypophysis, into young male mice caused marked degenerative changes in the testicle. In the case of older mice, the effect was less pronounced. ARTHUR GROLLMAN

The importance of the thiocyanate present in gastric juice. G. LOCKEMANN AND W. ULRICH. *Deut. med. Wochschr.* **56**, 1900–2(1930).—The presence of SCN^- in gastric juice greatly enhances its bactericidal power. ARTHUR GROLLMAN

Hormones. BENJAMIN HARROW. *J. Chem. Education* **8**, 661–9(1931).—A review
E. H.

The coenzyme of lactic acid formation of the muscle. KARL LOHMANN. *Naturwissenschaften* **19**, 180(1931).—Previously the coenzyme of lactic acid formation in the muscle was found to consist of an autolyzable and a non-autolyzable part, the former being adenylpyrophosphoric acid (*C. A.* **24**, 145; Meyer, *C. A.* **22**, 2580). It was now found that the non-autolyzable part can be replaced by Mg salt. The system dialyzed muscle ext. + inorg. phosphate + adenylpyrophosphate + Mg salt is able to split

glycogen into lactic acid. Absence of any of the 4 components inactivates the mixt. Muscle ext. inactivated after prolonged standing (4 days at 0°) by enzymic demolition of the adenylpyrophosphate (Meyerhof, *C. A.* **20**, 1635) can be reactivated by addn. of this substance or of adenylic acid but to a lesser extent. A slight reactivation is caused by inosinpyrophosphoric acid; no action is found on addn. of inosinic acid. An adenylpyrophosphoric acid similar to that in the skeleton muscles of vertebrates or that of non-vertebrates occurs in heart muscle. The Harden Young hexosediphosphoric acid and Embdens hexosemonophosphoric acid are only cleaved by adenylpyrophosphate in the presence of Mg, likewise for the reverse reaction. An additional case where this combination is essential to effective action is in alc. fermentation by dialyzed maceration juice or by washed yeast (washed in weakly acid soln.). The system Mg + adenyl pyrophosphate fulfills all conditions for a coenzyme. Its relation to that of Euler and Myrbäck (*Z. physiol. Chem.* **1923–30**; cf. *C. A.* **24**, 5312) is uncertain. The system is not active for methylglyoxalase (Neuberg, *C. A.* **7**, 2413; Dakin and Dudley, *C. A.* **7**, 1532).
B. J. C. VAN DER HOEVEN

The surface potential of the gastric mucous membrane in warm-blooded animals under various conditions. KURT KRAMER. *Z. Biol.* **91**, 26–36(1931).—Surface potentials of the gastric mucous membrane were derived by using KCl, HCl and NaOH in different concns. The direction and intensity depend entirely and characteristically on the soln. It seems that HCl can vary the permeability if its concn. is varied. Contrary to other membranes, these changes are very small and reversible. NaOH causes irreversible changes.
FRANCES KRASNOW

Investigation on the fluctuations of the potential of the gastric mucous membrane in warm-blooded animals. HANS SARRE. *Z. Biol.* **91**, 37–52(1931).—The initial potential is varied by changing the soln., in contact with the membrane. When acid gastric juice is in contact with the membrane, the potential is always negative, of variable height and depends upon the condition of the animal. At death the potential falls steadily and reaches positive values.
FRANCES KRASNOW

The influence of oxygen on the generation of lactic acid in the muscle of warm-blooded animals. AMANDUS HAHN, E. FISCHBACK AND H. NIEMER. *Z. Biol.* **91**, 53–62(1931).—In work on pig muscle it was found that in the presence of O_2 the lactic acid content of muscle mash may be kept const. The amt. of total carbohydrate remains const. or decreases very slightly.
FRANCES KRASNOW

The activity of the heart and the central nervous system of mammals during great oxygen deficiency. L. ASHER AND N. SCHEINFINKEL. *Z. Biol.* **91**, 66–72(1931).—In certain cases it was possible to maintain normal breathing and circulation by inspiring air contg. only 3% O_2.
FRANCES KRASNOW

Hydrogen-ion concentration of the alimentary tracts of fowl, cat and rabbit. ALVAH R. MCLAUGHLIN. *Science* **73**, 191–2(1931). —Fowls, rabbits and cats were killed very rapidly and the p_H value of the contents of several portions of the alimentary canal was measured by means of a quinhydrone electrode. The fowls and rabbits were killed very soon after feeding. All portions of the alimentary canal of the former were acid, while those of the latter were slightly alkaline excepting the stomach (p_H 1.83) and cecum (p_H 6.26). The results for the cats were uncertain because of the lack of knowledge of their past history; all portions were definitely acid.
I. M. LEVINE

The alleged presence of "bound potassium" in muscle. WM. E. CALLISON. *J. Biol. Chem.* **90**, 665–8(1931).—"The decrease in 'bound K' in muscle tissue placed in isotonic saline is related to the amt. and frequency of change of isotonic NaCl soln. and to the size of the pieces of muscle tissue. Autolysis for a period of 24 hrs. did not apparently affect the diffusion of K into the soln. The present expts. furnish no evidence for the existence of 'bound K' in muscle tissue" as claimed by Neuschloss (*C. A.* **20**, 3497, 3498) and corroborate the findings of Raab (*C. A.* **21**, 3227) and Höber (*C. A.* **23**, 3748). Neuschloss' method for the detn. of 'bound K' is unsatisfactory.
A. P. L.

Studies on arginine. I. The rate of catabolism of arginine in rats, including a method for the determination of arginine in biological material. VERN C. KIECH, JAMES M. LUCK AND ANNA EVELYN SMITH. *J. Biol. Chem.* **90**, 677–96(1931).—A volumetric method, in principle resembling that of Bonot and Cahn (*C. A.* **21**, 1471), is described for the detn. of very small amts. of arginine in protein-free tissue exts. The proteins are pptd. by H_2WO_4, the arginine is converted by arginase into ornithine and urea and the urea is detd. as dixanthydryl urea by oxidation with $K_2Cr_2O_7$ and H_2SO_4 according to the vol. procedure of Allen and Luck (*C. A.* **23**, 5206). Muscle tissue of fasting female rats contains an av. of 26.1 mg. of arginine per 100 g. and the whole carcass 27.5 mg. If administered subcutaneously, arginine is rapidly catabolized and the ornithine which would presumably be formed must be catabolized almost as rapidly

as less than 12% of the injected N is present at any time in substances other than urea and arginine. Bibliography of 26 references. A. P. LOTHROP

The distribution of blood sugar. MICHAEL SOMOGYI. *J. Biol. Chem.* 90, 731–5 (1931).—Folin and Svedberg (*C. A.* 25, 335) have recently reported a ratio of 60:100 for the distribution of corpuscle and plasma sugar for healthy persons and claim that the corpuscles in the blood of diabetics contain relatively more sugar than those of non-diabetics. S. has redetd. the values for true sugar using his new method of deproteinization (*C. A.* 25, 2165) and obtains results approx. the same as those previously reported (*C. A.* 22, 3204), 77:100, in both diabetics and non-diabetics. F. and S. detd. total reduction values and not true sugar in plasma and slight and negligible as the amt. of non-sugar reducing substances in plasma may appear (5–6 mg. %) it suffices grossly to distort the true picture of the distribution of sugar. If the figures are corrected to true sugar values by the deduction of 5 mg. % of reducing non-sugars, a rise in the distribution ratios occurs and at once removes the apparent difference between the ratios of normal and diabetic individuals which is actually non-existent. The corrected figures are well in accord with those obtained by S. A. P. LOTHROP

Local metabolism and tissue reaction. Further investigations of the relations between local metabolism and cell growth. GERHARD MEYER-DÖRKIN. *Beitr. path. Anat.* 85, 555–64(1930).—The growth-stimulating effect of solns. of inorg. salts upon the endothelial cells of the lymph spaces of white mice observed in earlier expts. (*C. A.* 24, 5358) was not observed in later expts. carried out under more carefully controlled conditions. E. R. MAIN

The physiologic variations in the inorganic blood phosphorus content at the different age periods. An attempt to explain these in the growing child. J. K. BULLOCK. *Am. J. Diseases Children* 40, 725–40(1930).—The inorg. P content of the serum of new born infants is 4.82 mg. per 100 cc. It increases rapidly to a value of 5.66 mg. per 100 cc. at the 7th month. From this time it tends to diminish gradually until the 19th or 20th yr., the period of termination of osseous growth, and then remains more or less const. The age periods of most rapid growth do not show as marked an increase in inorg. P as the seasonal periods of most rapid growth. E. R. MAIN

The intermediate metabolism of fats. The influence of the administration of certain fatty acids of the aliphatic series on ketogenesis and on the acid-base equilibrium of the organism in diabetics and on patients suffering with liver disturbances. L. CANNAVO. *Boll. soc. ital. biol. sper.* 5, 805–10(1930).—The acidosis caused by the administration of various fatty acids and the relation of acidosis and the production and elimination of "ketone bodies" were studied clinically on patients. From the data accumulated, it appears that all or nearly all the acids of the aliphatic series produce acidosis however, only those which contain an odd no. of C atoms are intensely ketogenic The acidosis caused by the administration of acids with the odd no. of C atoms may be due to non-ketogenic org. acids formed from the former by the degradation of their mols. Whenever, as a result of the administration of fatty acids there arose a more or less intense acidosis, an increase of NH_3 in the urine was observed. In patients with hepatic lesions a fair amt. of ketones was observed in the blood and urine; this points to a diminution of the function of the hepatic cell which in all probability is a factor in hepatic acidosis and coma. PETER MASUCCI

The reticulo-endothelial system in the defense of the organism. LAMBERTO LENZI. *Boll. soc. ital. biol. sper.* 5, 825–8(1930).—Contrary to what has been observed with inorg. poisons, animals which have been previously stimulated with metallic colloids (collargol) do not become more resistant to org. poisons (morphine-HCl or quinine sulfate). PETER MASUCCI

Experimental studies on the influence which blood plasma exerts on arterial pressure in contrast to that exerted by the corpuscles. LUIGI SPADAFINA. *Boll. soc. ital biol. sper.* 5, 829–32(1930).—Repeated infusions of distd. H_2O in dogs such that the no. of corpuscles was reduced to $^1/_2$ or even $^1/_4$ of the normal did not appreciably change the arterial blood pressure. Injections of pyridine, subcutaneously or intravenously, reduced the corpuscles to $^1/_4$ the normal, but did not change the arterial pressure. These results lead S. to conclude that plasma plays a much more important role in the maintenance of the normal blood pressure than the blood corpuscles. PETER MASUCCI

The sedimentation of the blood studied by means of the nephelometer. IV. The influence of the viscosity of the medium. A. AGGAZZOTTI AND G. BUCCIARDI. *Boll. soc. ital. biol. sper.* 5, 867–9(1930); cf. *C. A.* 24, 1897.—By increasing the viscosity of Ringer soln. by the addn. to it of glycerol, starch or glucose, and using the modified Ringer as a diluent for blood (9.1% citrated blood), the variations in the luminosity which precede and follow sedimentation of the corpuscles are changed markedly. The

increase of the initial luminosity which precedes the beginning of sedimentation is noticeably retarded. PETER MASUCCI

The permeability coefficient of aqueous solutions of lactic acid on muscle. P. ROWINSKI. *Boll. soc. ital. biol. sper.* 5, 899–901(1930).—Frog muscle prepns. were perfused with Ringer soln. (without bicarbonate) and after having frozen and powd. the muscles with liquid air, lactic acid was detd. (*1*) *Perfusion with Ringer soln. contg. lactate.*—The lactic acid in the muscle increased with increasing concn. of the salt in the perfusion liquid. (*2*) *Perfusion with Ringer soln. contg. lactic acid.*—The concn. of lactic acid in the muscle varied according to the concn. of the acid in the perfusion liquid. Up to 40 mg. % (p_H 3.0) the lactic acid in the muscle increased rapidly, but with greater concns. the increase became slower. (*3*) *Perfusion with Ringer soln. contg. HCl.*—When the liquid coming out of the muscle had a p_H of 6.8 the amt. of lactic acid was normal, but when the muscle failed to regulate the p_H of the circulating liquid, the amt. doubled. P. M.

Studies on the surviving hepato-pancreatic preparation. I. The metabolism of fats. OSCAR CANTONI. *Boll. soc. ital. biol. sper.* 5, 918–21(1930).—The fatty acid content of the blood did not vary noticeably in fasting animals but did decrease in dogs with alimentary lipemia. The circulating fatty acids apparently went through a process of desaturation as evidenced by the lowering of the m. p. and solidification point, and by the increase of the iodine no. **II. The metabolism of cholesterol.** *Ibid* 921–2. The diminution of cholesterol during circulation was gradual, const. and independent of the amt. of alimentary fat. **III. The respiratory exchange.** *Ibid* 922–4. The R. Q. was generally low, indicating intensive oxidative processes. **IV. The ureopoietic function of the liver.** *Ibid* 924–5. There was an increase of urea in the blood flowing from the liver. The increase was gradual, const. and bore no relation to the alimentary fat. PETER MASUCCI

The lipoidal hormone of the hypophysis and the vitamin of fertility. RENZO AGNOLI. *Boll. soc. ital. biol. sper.* 5, 937–9(1930).—Some preliminary evidence is offered that the lipoidal hormone of the anterior pituitary lobe is similar to the fat-sol. vitamin E. PETER MASUCCI

The action of adrenaline on the reduction processes of frog muscle pulp. M. COMEL. *Boll. soc. ital. biol. sper.* 5, 932–4(1930).—With methylene blue or *m*-dinitrobenzene as indicators, adrenaline in concns. of 10^{-6} to 10^{-12} when added to frog muscle pulp did not accelerate or inhibit reduction processes. PETER MASUCCI

Experimental uricolysis in the heart-lung preparation. GINO BERGAMI. *Boll. soc. ital. biol. sper.* 5, 934–6(1930).—Uric acid injected into the heart-lung prepn. is not destroyed. The addn. of uricase to the blood circulating in the prepn. causes only a slight diminution of the uric acid content PETER MASUCCI

Parathyroids and irradiated ergosterol. G. GANFINI. *Boll. soc. ital. biol. sper.* 5, 953–5(1930).—Irradiated ergosterol cannot be substituted for the parathyroid hormone; the former merely retards tetany without influencing cachexia. PETER MASUCCI

The influence of nonelectrolytes on the buffer action of animal and vegetable organs. GIUSEPPE RUSSO. *Boll. soc. ital. biol. sper.* 5, 963–5(1930).—The aim was to establish whether a given organ displaces with equal intensity the reaction of 2 isotonic solns. of equal p_H. The nonelectrolytes used were urea, glucose, sucrose and galactose; the electrolyte was NaCl. The results show that nonelectrolytes aid in an acid reaction and inhibit in an alk. reaction the unfolding of the buffering action of tissues, *e. g.*, NaCl and glucose soln. had initial p_H of 8; after shaking both with equal amts. of frog leg tissue and for equal lengths of time, the NaCl had a p_H of 7.18, the glucose p_H 7.45. When the initial p_H was 5, after the solns. were shaken with the tissue, the NaCl soln. had a p_H of 5.65, the glucose p_H 5.93. This behavior explains in all probability the action of nonelectrolytes on the permeability of protoplasm. PETER MASUCCI

The so-called influence of the suprarenal medulla on alimentary hyperglucemia. S. RACCHIUSA AND A. CRISERA. *Boll. soc. ital. biol. sper.* 5, 993–6(1930).—Dogs subjected to the complete or incomplete ablation of the suprarenal capsule showed, immediately after the operation, a marked lowering of temp. which reached 34–35° in some cases. After the complete ablation of the suprarenal medulla, and in some cases after the removal of the greater part of the cortex, not only was there no hypoglucemia but in some cases there was a tendency toward hyperglucemia after the administration of glucose. PETER MASUCCI

The direct action of follicular liquid on the motility of the tubes. LUIGI MANZI. *Boll. soc. ital. biol. sper.* 5, 1020–5(1930). PETER MASUCCI

The energy of movement of spermatozoa. E. E. IVANOV. *Z. Tierzucht. Zuchtungsbiol. Tierernahr.* 20, 404–18(1931).—The onward movement of dog spermatozoa

lasts several hours in an anaerobic medium where the traces of O_2 present are entirely insufficient to supply the normal O_2 need. This movement under anaerobic conditions is not related to the production of CO_2. It can occur in a medium where cell respiration has almost entirely ceased as the result of the addn. of KCN. The energy for spermatozoa movement does not come from oxidation processes. The role of spermatozoa respiration consists obviously of the removal of products of decompn. processes which, where a lack of O_2 occurs, furnishes the necessary energy for movement. In the presence of O_2 the spermatozoa are very mobile even in very concd. suspensions. Under anaerobic conditions the more concd. the suspension the shorter is the period of movement.

L. A. MAYNARD

The hydremic curve for resting, marching and running. U. CASSINIS AND L. BRACALONI. *Arch. fisiol.* **28**, 128–41(1930); cf. *C. A.* **24**, 4814.—In rest, the variations are insignificant; during marching some subjects show a marked decrease in the curve, whereas in the majority the changes are slight. During running, the hydremic curve drops abruptly, but soon returns to normal. The changes are not in relation to variations in body wt.

A. E. MEYER

Lymphoganglin and choline. GAETANO VIALE. *Arch. fisiol.* **28**, 150–5(1930).—The vagotropic action of lymphatic gland ext. is not due to choline, but to vagotropin, a substance existing in the lymph and not precipitable by phosphotungstic acid. The cardio-vascular action due to lymphoganglin is usually attributed to exts. of the most different organs

A. E. MEYER

The cholesterolemia in pregnancy and puerperium. NICANOR PALACIOS COSTA AND MIGUEL V. FALSÍA. *Semana méd.* (Buenos Aires) **1931**, I, 428–34; *Rev. soc. argentina biol.* **6**, 99–107; *Compt. rend. soc. biol.* **104**, 1024(1930).—In the last 2 months of pregnancy, the cholesterol in blood is increased, that in the duodenal fluid in only 33% of the cases. A further increase was observed during labor. The cholesterol decreased in the blood during the first week of the puerperium, but did not turn to normal. The cholesterol in the blood of the umbilical vein was 0.108%, that in the duodenal liquid of normal persons 0.059%.

A. E. MEYER

Comment on P. Rona and W. Fabisch's paper: Studies on blood sugar. II. KURT P. JACOBSOHN. *Biochem. Z.* **231**, 498–9(1931).—Polemical (cf. *C. A.* **25**, 332)

S. MORGULIS

An investigation into the gastric secretion of a hundred normal persons over the age of sixty. DANIEL T. DAVIES AND T. G. ILLTYD JAMES. *Quart. J. Med.* **23**, 1–14 (1931).—In a series of 100 persons from 60 to 95 yrs. of age, 43 had a normal secretion of HCl, 13 had a high, 12 a diminished and 32 no secretion of HCl. Small vols. of juice and an inhibition of secretion during the first 1 to 1.5 hrs. were common to all. Enzyme action bore little relation to HCl secretion. Pepsin was never completely absent.

JOHN T. MYERS

The sugar content of the blood in elderly people. F. W. MARSHALL. *Quart. J. Med.* **24**, 257–84(1931).—Five types of glucose-tolerance curves occur in healthy old people: the normal adult, the lag, the flat, the storage defect and the typical diabetic. The storage defect is most frequent. The renal threshhold in healthy old age is generally raised, and is in the neighborhood of 0.200%.

JOHN T. MYERS

Quantitative and qualitative variations in the production of milk by cows under the effects of castration. J. ALQUIER AND G. SILVESTRE DE SACY. *Bull. soc. hyg. aliment.* **18**, 436–63(1930).—Contrary to a no. of published data, castration had but little effect on the progressive natural decrease of the activity of the mammary glands when the latter remains undisturbed by gestation; with some races (Normandy) there was practically no effect. Castration does not preserve cows from the unfavorable effects of certain modifications in diet which reduce the quantity and quality of the milk. It does not appreciably increase the production of butter fat and casein, but merely increases the ash content (more particularly the CaO) of the milk. No difference was observed in the biol. value (vitamin contents) of the milk of the castrated and uncastrated animal.

A. PAPINEAU-COUTURE

Hormonal test of pregnancy. ADÈLE BROUHA. *Compt. rend. soc. biol.* **106**, 6–7 (1931).—A description of a new hormonal test giving quick, accurate results. A. L. R.

Some histochemical characteristics of a melanic propigment. L. LISON. *Compt. rend. soc. biol.* **106**, 41–3(1931).—A histochem. study was made of a premelanic chromogen obtained from the middle of the hair bulbs of embryonic cat skin fixed by formol soln. The substance appears as clear, yellow rods; it takes on a beautiful orange tint when treated with the tetrazo deriv. of dianisidine in an alk. medium because of the formation of an azo dye by the combining of a tetrazo deriv. of dianisidine with the pre-melanic chromogen, indicating the presence of a benzene nucleus contg. at least one OH

group. Ammoniacal AgOH colors the yellow rods an intense black, demonstrating a reducing power; this is not due to an aldehyde group, however, because decolorized fuchsin does not have its color restored; neither is it due to the presence of 2 phenol groups, nor to the presence of one phenol and one aromatic amine group, since the chromaffin reaction is negative; on the contrary, prolonged oxidation by alk. dichromate causes the rods to disappear, an irreversible reaction as shown by treatment with reducing agents. The expts. of Bach and Haehn on the action of tyrosinase on tyrosine make it possible to deduce the presence of a quinonic nucleus; *in vitro* the quinone is condensed very easily with tyrosine to give derivs. with properties very similar to those described for the melanic propigment; therefore L. concludes that this latter substance is a condensation product of a compd. having a phenolic base like tyrosine, with a deriv. possessing a quinonic structure. This compd., first stage of melanogenesis, preserves intact a phenolic hydroxyl. ALBERT L. RAWLINS

The relation existing between the factors determining the amount of oxygen consumption of the organism. G. LITARCZEK, H. AUBERT, I. COSMULESCO AND B. NESTORESCO. *Compt. rend. soc. biol.* **106**, 108-10(1931).—The following equation is derived:

$$O_2 = \text{Output} \times HbO_2 \times \frac{[100x_a^n]}{(^1/k_a) + x_a^n] - \frac{[100x_v^n]}{(^1/k_v) + x_v^n]}}, \text{ where}$$

output is the quantity of blood which passes through the capillaries from the arterial to the venous system, expressed numerically by considering 100 cc. as unity; HbO_2 is the total O_2 capacity of the blood; $^1/k_a$ and $^1/k_v$ are the consts of dissociation of the oxyhemoglobin of arterial and venous bloods, resp.; x_a and x_v are the tensions, resp., of arterial and venous O_2 expressed in mm. of Hg. ALBERT L. RAWLINS

The growth-promoting hormone of the pituitary body. H. B. VANDYKE AND ZONJA WALLEN-LAWRENCE. *J. Pharmacol.* **40**, 413-22(1930).—An alk. ext. of the anterior lobe, which appears to be free of the luteinizing principle, further purified by filtration through a Berkefeld filter, pptn. with Na_2SO_4, dialysis, etc., is described. A method of assay is given; it involves the use of hypophysectomized or normal adult rats. C. R.

A critical study of the assay of female sex hormone preparations. F. E. D'AMOUR AND R. G. GUSTAVSON. *J. Pharmacol.* **40**, 473-84(1930).—The work of Coward and Burn (*C. A.* **22**, 632) on standardization of female sex hormone prepns. was repeated. D'A. and G. agree with Coward and Burn that the rat unit should be the amount of hormone necessary to produce estrus in 50% of a large group of animals, and that a standard unit be used by all workers. C. RIEGEL

The preparation and assay of crystalline female sex hormone. F. E. D'AMOUR AND R. G. GUSTAVSON. *J. Pharmacol.* **40**, 485-8(1930).—Prepn. of a cryst. estrin is described which on assay showed 1 rat unit equal to 0.38γ C. RIEGEL

The diuretic hormone of the brain. J. OLIVET. *Münch. med. Wochschr.* **77**, 58-9 (1930).—A substance with a strong diuretic action is mobilized by stimulations of certain portions of the brain. The substance was isolated to the extent that it was active when administered to other animals. The hormone is formed in the midbrain. R. C. WILLSON

NEWBURGH, LOUIS H., AND JOHNSTON, MARGARET W.: **The Exchange of Energy between Man and the Environment.** Springfield, Ill.: C. C. Thomas. 104 pp.

G—PATHOLOGY

H. GIDEON WELLS

Presence of pancreatic enzymes in the bile. H. L. POPPER. *Wiener klin. Wochschr.* 42, 800-3(1929).—In certain pathol. conditions the bile, which usually contains no diastatic enzyme, showed high diastatic values. B. C. A.

Ketosis in seasickness. J. R. MARRACK. *Brit. Med. J.* **1931, I**, 178-9.—Ketosis occurs in seasickness after vomiting appears, sometimes before. Ketosis is not the cause of seasickness, but rather is an evidence of some unknown metabolic disturbance. J. B. BROWN

Relation of calcium to the hemorrhagic tendency in obstructive jaundice. ROBERT R. LINTON. *Ann. Surgery* **93**, 707-21(1931).—The lowered coagulability of the blood in cases of obstructive jaundice does not seem to be due to a deficiency or abnormality of the blood Ca. The most effective means of preventing and stopping post-operative hemorrhage in obstructive jaundice is repeated direct blood transfusions used in conjunction with a high carbohydrate and fluid intake. RACHEL BROWN

Certain biochemical aspects of lobar pneumonia. D. P. CUTHBERTSON. *Glasgow Med. J.* **34**, 64–7(1931).—In lobar pneumonia the arterial blood is unsatd. with respect to O, although the O capacity is not reduced. The free CO_2 and the total CO_2 contents of the blood are diminished, although the capacity to combine with CO_2 is not appreciably below normal. RACHEL BROWN

The azoprotein gelatin-aniline. M. ADANT. *Compt. rend. soc. biol.* **103**, 541–3 (1930).—By coupling aniline to gelatin, gelatin acquires antigenic properties. The serum obtained by immunizing with gelatin-aniline precipitates its antigen as well as gelatin and the azoproteins obtained by coupling aniline to the serum proteins. B. C. BRUNSTETTER

The precipitation of azoproteins. M. ADANT. *Compt. rend. soc. biol.* **103**, 950–1 (1930).—The antigen produced by the injection of an azoprotein (precipitin) was added to the corresponding azoprotein; the resulting ppt. was centrifuged off. To one part of the supernatant liquid, more precipitin was added; to another part, more azoprotein was added and a third part was kept as control. Only in the first case was an abundant ppt. produced; slight ppts. formed in the other two cases. B. C. BRUNSTETTER

The regulation of the blood sugar in malaria. E. J. STERKIN. *Arch. Schiffs-Tropen-Hyg.* **34**, 504–15(1930).—Such variations as are found are not characteristic of malaria, but are observed in other febrile conditions. The blood sugar may be high, low or normal during an attack. H. EAGLE

The demonstration of antibodies in malaria. A. RADOSAVLJEVIĆ. *Arch. Schiffs-Tropen-Hyg.* **34**, 629–43(1930).—Cases of malaria which have become afebrile may contain parasiticidal antibodies in the blood. When their serum is incubated with blood drawn from active cases, the mixt. is no longer infectious. This parasiticidal action requires the presence of complement. Injected into febrile patients, this convalescent serum sometimes causes a fall in temp. and a coincident disappearance of organisms from the blood. H. EAGLE

Biochemical characteristics of leprosy. A. S. RAYEVSKII. *Arch. Schiffs-Tropen Hyg.* **34**, 651–7(1930).—In leprosy there is frequently a disturbance in the carbohydrate metabolism, manifested by hypoglucemia, with a very marked alimentary hyperglucemia. In stationary cases there is a pos. Ca^{++} balance, with decalcification during the active stages. In the active stages, blood $[Ca]^{++}$ falls, and $[K]^{+}$ rises. H. E.

Alkali reserve of the blood in relationship to the gastric acidity and the condition of the vegetative nervous system in certain disease groups. A. N. VOLODIN AND S. M. BELYAEV. *Arch. Verdauungskrankh.* **48**, 204–19(1930). H. EAGLE

Relationship of the true reaction of the urine and blood to ulcer disease and gastric secretion. HANS L. POPPER. *Arch. Verdauungskrankh.* **48**, 220–9(1930).—A deviation of blood p_H to the acid side is not characteristic of ulcer; moreover, a decreased excretion of alkali in the urine following the intravenous injection of $NaHCO_3$ does not indicate either gastric hyperacidity or the presence of ulcer. There is no correlation between blood p_H and gastric acidity. H. EAGLE

A case of hemoglobinuria in visceral leishmaniasis. J. PIKUL. *Arch. Schiffs Tropen-Hyg.* **34**, 358–60(1930). H. EAGLE

The determination of glucuronic acid in the urine is a test of liver function. JOACHIM SAUER. *Klin. Wochschr.* **9**, 2351–2(1930).—An increased excretion of glucuronic acid follows the ingestion of foods contg. it as glucosides; a decreased excretion is evidence of hepatic damage and constitutes a more sensitive test of hepatic function than, *e. g.*, the galactose test. A urine excretion of <0.2 g. is strongly suggestive of liver damage. H. EAGLE

Studies in immunity processes in syphilis. V. Immunobiological change in the Spirochaeta pallida and its significance for the course of the chronic infection. H. KRÓ AND N. V. JANCSÓ. *Klin. Wochschr.* **10**, 105–7(1931); cf. *C. A.* **24**, 5837.—By repeated transfers onto media contg. increasing quantities of rabbit antiserum it is possible to obtain a variant of *Sp. pallida* which, unlike the original strain, is not killed by the antiserum; simultaneously, the organism loses the property of causing the formation of spirocheticidal antibodies when injected into the rabbits. The original culture forms complement-fixing antibodies against itself when injected into rabbits, but not against this serum-resistant strain, while the latter forms similar antibodies against both types. By subculture on ordinary serum-bouillon, the variant loses its acquired immunity and becomes susceptible to an antiserum. The authors suggest that the behavior of the spirochaete in the human organism may be analogous to these findings. H. EAGLE

The iodine-deficiency theory of goiter. JOHAN HOLST. *Klin. Wochschr.* **10**, 118 (1931).—H. agrees with Hellwig in that goiter may be endemic in areas in which there

is no I deficiency. However, I deficiency may be one of several possible causes of goiter. H. EAGLE

"Uremia" following protracted vomiting. PAUL MEYER. *Klin. Wochschr.* **10**, 155–7(1931).—Protracted vomiting may cause acidosis, increased nonprotein-nitrogen in the blood, anuria and even convulsions, without any anatomical changes in the kidneys. In one case, the administration of insulin, glucose and physiol. NaCl soln. caused the disappearance of all symptoms. H. EAGLE

The color of the urine in diffuse hematogenous kidney disease. ERWIN BECHER. *Klin. Wochschr.* **10**, 157–60(1931). H. EAGLE

The demonstration of brain antibodies in human syphilis. F. GEORGI AND Ö. FISCHER. *Klin. Wochschr.* **10**, 207–10(1931); cf. *C. A.* **24**, 5852.—The mere fact that an alc. ext. of brain may give complement fixation with syphilitic spinal fluid and not with blood from the same patient does not prove the presence of brain antibodies in the fluid. The same phenomenon can be produced with any organ ext. by proper diln. and is due to the fact that spinal fluid continues to react even with high dilns. of alc. ext., while the serum does not. A concd. brain ext. gives complement fixation with the spinal fluid and serum from many non-syphilitic, organic neurological conditions, which strongly indicates that there may be a true antibody to brain lipoids. H. EAGLE

The electrolyte content of the blood in a case of diabetes insipidus. M. GRADWOHL. *Deut. med. Wochschr.* **56**, 1700–2(1930).—The blood in a case of diabetes insipidus showed an increased K, a decreased Ca, and an increased Na content. The H_2O-binding capacity of the corpuscles was increased. ARTHUR GROLLMAN

Value and duration of immunity conferred by antidiphtheritic anatoxin. Titration of antitoxin present in the serum of vaccinated children. G. RAMON AND ROBERT DEBRÉ. *Am. J. Diseases Children* **41**, 1–7(1931); cf. *C. A.* **24**, 2173.—The antitoxin content of the blood serum of children who have a neg. Schick test after immunization with diphtheria anatoxin is more than $^1/_{30}$ unit per cc. It is approx. the same whether 2 or 3 injections of anatoxin are given, but may be higher if a 4th injection is given and if there is a prolonged interval between 2 of the injections. It appears to be higher the older the child is when inoculated and does not tend to diminish with increase in the time after inoculation. E. R. MAIN

Cell and plasma chloride in the pyloric stenosis of infants. MONTAGUE MAIZELS AND CATHERINE B. MCARTHUR. *Am. J. Diseases Children* **41**, 35–44(1931).—The blood plasma of normal infants less than 3 months of age contains 22–28 millimols of bicarbonate ion and 96–106 millimols of chloride ion. The cells contain 44–56 millimols of chloride ion. In pyloric stenosis in infants, the p_H of the plasma and the concn. of bicarbonate are normal or increased. The chloride concn. of the plasma and of the cells is often decreased, the chloride content of the cells usually being lowered to a greater extent than that of the plasma. The vol. of the blood often is decreased and the relative vol. of the cells increased. E. R. MAIN

Dietary protein and blood-clotting function. I. NEWTON KUGELMASS AND EMMA LOUISE SAMUEL. *Am. J. Diseases Children* **41**, 48–52(1931); cf. *C. A.* **24**, 3547.—Prolonged feeding of a diet rich in protein tends to maintain the blood-clotting factors at a high level, thereby increasing the coagulability of the blood. An increase in the production of fibrinogen is induced by injury of the tissues through surgical intervention, and a transient increase by the introduction of heterologous proteins into the vascular system E. R. MAIN

Ossification. I. Callus formation and calcification. I. NEWTON KUGELMASS AND RICHARD N. BERG. *Am. J. Diseases Children* **41**, 236–48(1931).—Bone repair appears to be a local rather than a systemic process and may be, therefore, retarded or accelerated by locally applied agents. The degree and rate of calcification in experimentally induced fractures in rabbits are directly proportional to the amt. of available fibrous tissue. The union of the bones may be retarded by soln. of the fibrous tissue by means of the injection of an alk. soln. of trypsin at the site of the fracture. It may be accelerated by the stimulation of the production of fibrous tissue induced by the local injection of tissue fibrinogen. The local production of fibrous tissue does not appear to be altered by a diet high in protein. The Ca content of the blood tends to be higher and the phosphate content lower in the course of normal bone repair. A more rapid rate of calcification is assocd. with more marked alterations in the Ca and phosphate concns. E. R. MAIN

The proteolytic activity of the spleen in disease and hemorrhage. ARNOLD STRAUSS. *Beitr. path. Anat.* **85**, 251–77(1930).—The softening of the pulp tissue of spleens obtained at autopsy is assocd. with an increased proteolytic activity, which may be measured by the ability to liquefy gelatin or egg white. The optimum activity of the enzymes occurs

at p_H 8 and p_H 5. The enzymic activity is increased with the increase in time after death and is markedly increased in acute septic poisoning and post-hemorrhagic swelling. It is normal in spleens with chronic septic poisoning, in indurated and atrophied spleens and in those of children under 3–5 yrs. The presence of leucocytes appears to be an important factor in the degree of enzyme activity, since there is no proteolytic activity or softening of the pulp in animal spleens which contain no leucocytic enzymes. The softening of the adrenals appears to be assocd. with a purely autolytic rather than a proteolytic process. E. R. MAIN

The reactions of tissues and cells at artificial boundaries in the animal body. K. AKAMATSU. *Beitr. path. Anat.* 85, 349–70(1930).—The relation between the surfaces of small blocks of gelatin placed in the abdominal cavities of guinea pigs and the surrounding tissues appears to depend upon the concn. of H and OH ions within the blocks. The acid blocks have a marked tendency to adhere to and unite with the surrounding tissues. The alk. blocks have no tendency to unite with the tissues. The accumulation of leucocytes at the boundary surfaces and in the interiors is much more marked in the acid blocks. The leucocytes in the interior of the alk. blocks, although fewer in no., give a stronger test for the presence of oxidase. E. R. MAIN

The biologic and pathologic significance of copper, zinc and manganese. WALTER HERKEL. *Beitr. path. Anat.* 85, 513–51(1930).—The continued feeding of various salts of Cu to rabbits and rats does not induce cirrhosis of the liver. Large amts. of the ingested Cu accumulate in the liver, small quantities in the kidneys and very little in the bones. The amt. of Cu stored depends upon the amt. fed and the duration of the period of feeding and not upon the form in which it is fed. The normal liver contains from 6.5 to 36.1 mg. of Cu per kg. of dry substance. The values are doubled in pregnancy and are many times greater in the new-born. The Cu content of the liver in hemachromatosis is 24–384 mg. per kg. and is greatly increased in all other organs except the kidneys and bones. In cirrhosis without pigmentation the liver contains 67.6–374.9 mg. Cu per kg. The Zn content of the normal liver is 50–317 mg. per kg. of dry substance and is not increased in hemachromatosis. E. R. MAIN

The chemistry of hemosiderin. KURT W. SCHULTZE. *Beitr. path. Anat.* 86, 101–2 (1931).—The detn. of the amts. of ferric and ferrous ions present in the organs obtained at autopsy is extremely difficult, since the ferric ion is reduced rapidly during the 1st 6 hr. after death and the ferrous ion is then gradually oxidized. However, if an appreciable amt. of Fe is present, as in hemosiderosis of the liver, the quantity of free ferric Fe in the liver is much greater than in other organs examd. under identical conditions. HCHO and other preservatives of tissues hasten the oxidation of the ferrous ion. Expts. in which hemosiderosis is induced in animals by the injection of hemoglobin and distd. H_2O, while not conclusive, indicate that a large part of the Fe of hemosiderin exists in the ferric state. Procedures are described for the extn. of the free Fe of tissues by dil. acids with the exclusion of air and for the detn. of the total free Fe and the free ferrous and ferric Fe. E. R. MAIN

The Hinton glycerol cholesterol reaction for syphilis. Second modification. WM. A. HINTON AND ARTHUR BERK. *New Engl. J. Med.* 202, 1054–9(1930).—Supplementary procedures for the glycerol cholesterol reaction previously proposed (*C. A.* 24, 3828) are described which involve the use of a cholesterolized beef heart ext. and the formation of a characteristic ring instead of a ppt. E. R. MAIN

Blood cholesterol values in hyperthyroidism and hypothyroidism. Their significance. ROBERT L. MASON, HAZEL M. HUNT AND LEWIS HURXTHAL. *New Engl. J. Med.* 203, 1273–8(1930).—The cholesterol content of the blood tends to become decreased in hyperthyroidism, the lowest values being assocd. with severe toxemia. It becomes markedly increased in true myxedema. E. R. MAIN

Studies on anaphylaxis. VIII. The influence exerted by the liver on anaphylactic ictus and on peptone ictus, with particular reference to the experimental method and sources of error. ALBERTO MARRASSINI. *Boll. soc. ital. biol. sper.* 5, 833–7(1930). Guinea pigs were sensitized to egg albumin and to Witte peptone. The test dose was given after 19 days; part of the pigs received this dose in the jugular vein and part in a branch of the mesenteric vein. Amts. of egg albumin below certain limits when used for the test dose gave very different results with animals of the same weight. The shock varied from 0 to 6 according to the Arloing and Wauthey scale. The amt. of albumin which might produce a mortal ictus or an ictus of varying intensity even to total absence was about $^1/_6$ the dose which produced death with certainty in 250–300 g. guinea pigs. In guinea pigs 250–350 g. or over there was no relation between wt. of the animal and the dose of antigen necessary to produce a shock of equal intensity. These facts are ascribed to profound individual differences. 0.00150 g. albumin almost always

produced death; 0.00175–0.00250 g. constantly produced death. The results of slight or no shock reported by many authors who injected larger amts. of albumin must be accepted with much reserve; the same applies to results obtained with horse serum in doses of 0.05 cc., which corresponds to 0.003625 g. protein. The results obtained by injecting the test dose into the portal circulation were similar to those obtained when injected into the jugular vein. No definite ratio was found between the quantity of peptone necessary to produce sure death and the wt. of the animal. The weakest dose of peptone which produced a sure violent shock in 250–350-g. guinea pigs when injected into the jugular vein, when injected into the portal circulation gave slight or no shock in about $^1/_2$ the animals. PETER MASUCCI

Alkaline reserve in septic cases. RODOLFO REDI. *Boll. soc. ital. biol. sper.* **5**, 852(1930).—The alk. reserve values could not be used as a prognosis either for the duration or course of the disease. PETER MASUCCI

Studies on the acid-base equilibrium of the blood of septics (alkaline reserve, hydremia, glucemia, chloremia and urological examinations). RODOLFO REDI. *Boll. soc. ital. biol. sper.* **5**, 853–4(1930).—The causes which change the acid-base equil. of the blood of septic patients were investigated. The attempt was made to see whether the changes were due to the formation of an excess of acid substances, to a diminution of their neutralization or to their elimination. The results lead R. to state that there are too many factors to take into account to arrive at any definite conclusion. A knowledge of the alk. reserve in septic cases is of value only when considered along with other clinical findings. PETER MASUCCI

The adsorption of the virus of chicken sarcoma by hemoglobin. CLAUDIO PULCHER. *Boll. soc. ital. biol. sper.* **5**, 888–91(1930).—Electropos. hemoglobin adsorbs the virus; electroneg. hemoglobin does not. These results are in accord with cataphoresis expts. and show that the virus is negatively charged. PETER MASUCCI

The p_H and alkaline reserve of the blood in experimental intestinal occlusion. M. MAIRANO AND G. VECCHI. *Boll. soc. ital. biol. sper.* **5**, 912–5(1930); cf. *C. A.* **24**, 5853.– The exptl. intestinal occlusion obtained by sectioning the intestine provokes a progressive increase of the alk. reserve which runs parallel to the clinical picture. The increase of the alk. reserve bears no relation to the height of the occlusion. The p_H of the blood increases slightly, reaching a max. of 7.50–7.55 at the terminal period of the occlusion. PETER MASUCCI

Uroroseinuria and calcariuria as indices of hepatic insufficiency. S. GULLOTTA. *Boll. soc. ital. sper.* **5**, 971–3(1930). PETER MASUCCI

The acid-base equilibrium in dogs after cutting the vagi. G. QUAGLIARIELLO AND E. TRIA. *Boll. soc. ital. biol. sper.* **5**, 1016–9(1930).—After cutting both vagus nerves, the changes in the acid-base equil. of the blood were slight; there was a slight acidosis but this remained within limits compatible with life. There was also a slight diminution of blood bicarbonates. Marked changes, however, were noted in the urine. The concn. of bicarbonates increased and the acidity decreased because of the increase in NH_3. PETER MASUCCI

The influence of protein substances on the production of antibodies. I. G. ASCIONE. *Boll. soc. ital. biol. sper.* **5**, 1038–41(1930).—Beef serum albumin injected into rabbits 48 hrs. after each injection of typhoid or staphylococcus vaccine does not exert any influence on the production of antityphoid and antistaphylococcic agglutinins. The globulin of the same serum injected similarly inhibits the production of antityphoid agglutinins but accelerates the production of antistaphylococcic agglutinins in a concn. 3 times greater than the controls. **II.** *Ibid* 1042–4.—Two different strains of paratyphoid A were used. The rabbits immunized with bacteria and with lactalbumin yielded a serum with an agglutinating power no different from the controls. Similar results were obtained with rabbits immunized with bacteria and serum globulin. However, rabbits immunized with bacteria and serum albumin yielded a serum with a concn. of agglutinins 3 times greater than the animals receiving the bacteria alone. P. M.

A substance contained in lymph and lymphnodes producing hypoglucemia. PIO MARFORI. *Arch. fisiol.* **28**, 142–9(1930).—A fistula of the thoracic duct in a dog produces hyperglucemia but not glucosuria. Lymph and lymphoganglin compensate this increase of blood sugar. Both have a weak and inconst. action on the pancreas of the diabetic dog. The action is not due to insulin, but to a hormone antagonistic to adrenaline and acting by reduction of the activity of the vegetative sympathetic system. A. E. M.

The pituitary factor in arteriosclerosis. Its experimental production in rabbits. ROBERT C. MOEHLIG AND EUGENE A. OSIUS. *Ann. Internal Med.* **4**, 579–92(1930).—Marked production of atheromatous plaques in the rabbit aorta may be produced within

100 days by the feeding of a diet high in cholesterol and the daily injection of posterior lobe pituitary ext. JOHN T. MYERS

Natural bactericidal antibodies: observations on the bactericidal mechanism of normal serum. T. J. MACKIE AND H. M. FINKELSTEIN. *J. Hyg.* **31**, 35–55(1931).—Serum complement has no bactericidal action *per se*. An antibody-like substance invariably acts as an intermediary agent. This sensitizing agent is stable at 55° but labile at 60° to 65°. It is resident mainly in the fraction of the serum which is insol. in carbonic acid. It is present in the serum of young animals before certain other natural antibodies develop. The natural bactericidal antibodies are sp. for certain bacteria. A non-sp. extracellular substance occurs in bacterial cultures which may neutralize or inhibit these antibodies. This substance is liberated in large amts. when the culture is heated to 120°. It can be removed by repeated washing with saline soln. Strains of bacteria vary in their production of this substance. JOHN T. MYERS

The results of some quantitative experiments on the serum precipitation reaction. G. L. TAYLOR. *J. Hyg.* **31**, 56–83(1931).—Antigen and antibody react in equiv. proportions, in the serum pptn. reaction, to form an antigen-antibody complex which is adsorbent for suitable material in the surrounding medium. Excess of antigen is adsorbed and prevents completion of the reaction. Excess of antibody has no effect. Speed of particulation depends on the amt. of antigen-antibody complex and adsorbable matter present. There is some evidence that in certain cases the nature and amt. of adsorbable matter present may be such as to cause removal of excess antibody from the supernatent liquid. In such cases the adsorbable matter, not the antigen-antibody complex, may be adsorbent to the excess of antibody. The addn. of adsorbable matter as normal rabbit or guinea-pig serum is a useful method of hastening and facilitating the reading of reactions. JOHN T. MYERS

Observations on Salmonella agglutination and related phenomena. The influence of fresh normal serum on agglutination. P. BRUCE WHITE. *J. Path. Bact.* **34**, 23–37 (1931).—In concns. from 1:20 upward normal rat and rabbit sera inhibit sp. somatic agglutination of *Salmonella* bacilli with certain partial exception of coliform and proteus bacilli. Normal guinea-pig serum has similar properties but is much more apt also to have an agglutinative effect (conglutination). Normal serum has little effect on flagella agglutination. The inhibiting property disappears rapidly at 55°. Killed cultures, particularly alc.-treated ones, are more readily inhibited. Hemolytic complement is necessary for this inhibition, but another more stable factor must be present. Inhibition fails if the NaCl concn. is more or less than 0.85%. JOHN T. MYERS

The effect of variations in the media on the growth of normal and malignant tissues in vitro. F. C. PYBUS AND H. T. FAWNS. *J. Path. Bact.* **34**, 39–44(1931).—Preheating at 55° confers an inhibiting action on normal tissue growth which is not compensated by complement, but favors the growth of carcinoma. Pregnant serum has a stimulating effect on tissue growth. Embryonic and testis ext. stimulates the growth of embryonic tissues, the amt. of growth in 24 hrs. being double that in control cultures. J. T. M.

Schwartzman's phenomenon of local skin reactivity to bacterial products. F. M. BURNET. *J. Path. Bact.* **34**, 45–60(1931). A substance can be obtained by washing young bacterial cultures with isotonic NaCl soln., which on intradermal injection in rabbits produces a transient modification of the locally infiltrated tissues so that when the same substance is injected intravenously about 24 hrs. later an acute purpuric and necrotic reaction appears over the infiltrated area 2 or 3 hrs. later. This substance closely resembles bacterial endotoxins. Formalin-treated exts. give typical reactions when used as a skin preparatory agent but will function as the intravenous provocative agent. JOHN T. MYERS

Observations on melanosis coli. M. J. STEWART AND ELLA M. HICKMAN. *J. Path. Bact.* **34**, 61–72(1931).—Melanosis coli is due to the deposition of a melanin-like pigment within large mononuclear cells in the mucous membrane of the intestine, limited usually to the large intestine and appendix and ranging in color from gray or buff through dark gray or brown to inky black. Metastasis of the pigment may occur into the submucosa and the mesenteric lymph glands. The most acceptable theory of the mode of formation of this pigment is that of Pick, *i. e.*, that aromatic protein disintegration products are absorbed from the colon and converted into melanin within the connective tissue cells by the action of a tyrosinase-like enzyme. JOHN T. MYERS

The intermediate zone phenomenon encountered in certain Br. abortus agglutinating sera. F. W. PRIESTLEY. *J. Path. Bact.* **34**, 81–9(1931).—The nature of the agent causing inhibition at certain zones is obscure. It is pptd. from serum with the agglutinin in the globulin fraction and is removed by the homologous organism. An increase in NaCl concn. will remove the zone; this indicates that the zone is due to an in-

sufficient reduction of potential at that point and not to a decrease of cohesive force.
JOHN T. MYERS

The hypochlorhydria of asthma in childhood. GEORGE W. BRAY. *Quart. J. Med.* 24, 181–97(1931).—Asthmatic children, in general, show a markedly diminished power of secreting acid gastric juice in response to a test meal. Acid therapy should be combined with allergic treatment.
JOHN T. MYERS

The electrical charge of the virus of foot and mouth disease. IRMENGARD SICHERT-MODROW. *Zentr. Bakt. Parasitenk.*, I Abt., 119, 12–7(1930).—The virus carries a neg. charge. It is not known whether this is an actual property of the virus or of some substance which acts as a carrier.
JOHN T. MYERS

Lipoid antibodies. IV. The origin and proof of syphilitic blood changes. FELIX KLOPSTOCK. *Zentr. Bakt. Parasitenk.*, I Abt., 119, 78–84(1930); cf. *C. A.* 22, 3453.—There are lipoid compds. in the spirochetes which produce specific antibodies in rabbits and horses. The infected human patient acquires the power of combining with these substances during the early course of the disease so that antibodies may not appear till later.
JOHN T. MYERS

Hypoglucemic intoxication in trypanosomiasis, etc. KURT SCHERN. *Zentr. Bakt Parasitenk.*, I Abt., 119, 297–302(1931). —In exptl. animal trypanosomiasis, liver function is disturbed. No yeast-fermentable substance can be extd. from the liver. Only minimal quantities of sugar remain in the liver and blood.
JOHN T. MYERS

The influence of bacteriophage on the partial antigens of several microörganisms. MINORU TOYODA. *Zentr. Bakt. Parasitenk*, I Abt., 119, 350–3(1931).—After soln. by bacteriophage, the partial antigens remain in the lysate; their structure is not changed appreciably.
JOHN T. MYERS

Enzyme studies on the virus of foot and mouth disease. K. POPPE AND G. BUSCH. *Zentr. Bakt. Parasitenk.*, I Abt., 119, 398–406(1931). —The virus contained amylase, lipase and oxidase, but catalase, reductase and urease were not found. Virulence increases with the amt. of lipase, oxidase and amylase. In infected guinea pigs there is an increase of blood amylase but not of catalase.
JOHN T. MYERS

The true sugar content of skin and of muscle in diabetic and non-diabetic persons. HARRY C. TRIMBLE AND BENJAMIN W. CAREY, JR. *J. Biol. Chem.* 90, 655–63(1931).—In non-diabetic individuals the true (fermentable) sugar content of skin and of muscle averaged 56 and 28 mg. %, resp., and in diabetics 144 and 51 mg. The elevation of blood sugar is thus accompanied by a marked absolute increase of the quantity of sugar in the skin and a much smaller elevation in muscle. In diabetics who had received insulin at short intervals previous to operation, the sugar content of the muscles averaged almost the same as in the group in which externally administered insulin was no longer believed to be exerting an effect. These results are similar to those obtained by Folin, Trimble and Newman (*C. A.* 22, 267) using exptl. animals.
A. P. LOTHROP

The oxidation by potassium ferricyanide of certain constituents of the serum in anemia. G. PAYLING WRIGHT AND BARBARA ARTHUR. *J. Biol. Chem.* 90, 757–69 (1931).—Unsatd. fatty acids are oxidized by $K_3Fe(CN)_6$, and when these substances are present in the blood in any quantity as in anemia, the Haldane method for blood O_2 detns. is unsatisfactory and recourse must be made to Van Slyke's modification in which the ferricyanide-serum mixts. present a much smaller surface of contact with the O_2, which in turn is at a low partial pressure. The progress of an anemia produced by hemorrhage is accompanied by an increase in the I absorption value of the serum fats and by an almost quant. similar increase in the oxidizability of the serum by $K_3Fe(CN)_6$. After oxidation of the serum the I absorption values of the serum fats fall. The oleic acid present in the serum is probably only in a minor measure responsible for the oxidation reaction with $K_3Fe(CN)_6$, other more highly unsatd. fatty acids accounting for a greater part of it.
A. P. LOTHROP

The increase in production of tetanic antitoxin by addition of non-specific substances to the antigen. G. RAMON AND E. LEMÉTAYER. *Compt. rend. soc. biol.* 106, 71–4 (1931).—The addn. to the antigen of certain non-specific substances, such as alum, $CaCl_2$ and tapioca, exerts considerable stimulation on the development of antitoxic immunity and on the production of sp. antitoxin.
ALBERT L. RAWLINS

Tests on the relation between the increase of production of antitoxin and the hyperleucocytosis provoked. V. SORTUZ. *Compt. rend. soc. biol.* 106, 77–9(1931).—The production of tetanic antitoxin is greatly increased by the addn. to the antigen of a substance capable of producing at the same time a strong leucocytosis (for example, alum, $CaCl_2$ and tapioca). The antitoxin production is greatest when the leucocytosis reaches its highest level.
ALBERT L. RAWLINS

The ionic equilibrium of serum. Relations between the concentration of the salts

and the equilibrium of the albumin–globulin system. P. LECOMTE DU NOÜY. *Compt. rend. soc. biol.* **106**, 85–7(1931).—Results are given which were obtained in studying quantitatively the phenomenon of pptn. following the diln. of salt concn. by the addn. of distd. water to normal, heated and unheated, serum. ALBERT L. RAWLINS

Icteric bradycardia with hyperpotassemia. DUMITRESCO-MANTE, DULUGEA AND IONESCO-CRAIOVA. *Compt. rend. soc. biol.* **106**, 116–7(1931).—Four cases of icteric bradycardia are reported in which the blood modifications were characterized by hyperpotassemia, two of the cases being accompanied also by hypercholemia. A. L. R.

p_H and antigen of McIntosh in the Bordet-Wassermann reaction. B. ZABLOCKI AND S. SIERAKOWSKI. *Compt. rend. soc. biol.* **106**, 129–30(1931).—The action of the antigen of McIntosh is not affected by variations in the p_H between 3.5 and 9.0. When the reaction is acid a cloudiness appears, which diminishes as the soln. is made alk. At p_H 3.5 floccules appear; after centrifuging, the clear, supernatant liquid does not give a reaction with the positive serums; on the other hand, the sediment gives a pronounced reaction. These floccules appearing at p_H 3.5 may be divided into large and small floccules by centrifuging, the latter giving the stronger reaction with serum. ALBERT L. RAWLINS

p_H and the reaction of Kahn. S. SIERAKOWSKI AND B. ZABLOCKI. *Compt. rend. soc. biol.* **106**, 130–1(1931).—The emulsion of the antigen of Kahn, properly mixed with a soln. of physiol. serum, has a p_H of 5.8–6.5. After acidification, starting from about p_H 5.0, the antigen gives a positive reaction with a negative serum (*i. e.*, a non-specific result); this is explained by the fact that the antigen itself gives a sediment which is insol. after neutralization by the serum. In this respect the antigen of Kahn differs fundamentally from the antigen of Sachs. The antigen of Kahn made alk. with NaOH gives sp. but more feeble results, thus acting like the antigen of Sachs. Acidification or alkalization of the antigen of Kahn has no influence on the final p_H of the reaction, the buffering power of the antigen being quite strong, but weak in comparison to the great buffering power of the serum; the mixt. of the antigen and serum causes neutralization. The best results have been obtained with emulsions of Kahn having p_H 6.0–6.5. An antigen giving bad results can be corrected by the addn. of 0.5% of AcONa directly to the alc. soln. of antigen. The action of serum on the reaction of Kahn shows positive results in all cases after acidification starting at p_H 5.5; after alkalization to p_H 9.0, more feeble results are obtained with the positive serums; starting with p_H 10.6, all positive serums give negative results. ALBERT L. RAWLINS

p_H and the reaction of Sachs-Georgi. S. SIERAKOWSKI AND J. MELZAK. *Compt rend. soc. biol.* **106**, 132–3(1931).—See *C. A.* **25**, 739. A. L. RAWLINS

Physicochemical studies in gallstone formation. I. The method of the determination of the streaming potential and the applicability of Schulze-Hardy's rule. Appendix: The relation between the ζ-potential and coagulation. NOBORU FURUTANI, TSUKASA KUROKOCHI AND YOSHIO ASODA. *Japan J. Gastroenterol.* **2**, 148–57 (1930).—An app. is described for measuring the e. m. f. set up by the flow of aq. solns. of electrolytes through a glass capillary under pressure. The e. m. f. is proportional to the pressure but independent of the diam. and length of the capillary, within the limits of the expts. The streaming potential decreases in the order of KCl, $BaCl_2$, $AlCl_3$ and $Th(NO_3)_4$ in the same mol. concn. (cf. *C. A.* **22**, 4345). Lyophobic sols are coagulated by a soln. of electrolyte when the streaming potential of the latter becomes sufficiently low. This corresponds to a high concn. of univalent electrolytes, a lower concn. of bivalent, and an even lower concn. of tervalent and quadrivalent electrolytes. Crystal violet behaves like the latter. **II. The lyotropic series and the influence of acids and alkalies. Appendix: The relation between the ζ-potential and adsorption.** *Ibid* 158–61. The streaming potential of cations of the same valence decreases in the order Li, Na, K, Rb, NH_4 and Cs—and Mg, Ca and Ba, all tested as chlorides. The potential of HCl attains a much higher max. with increasing concn. than any of the salts tested. The max. potential of NaOH is much higher than that of HCl. The order for the adsorption of univalent cations (cf. Oden, *C. A.* **5**, 3535) is the same as that for their potential increasing from Li to Cs. **III. The influence of anions and halogen group. Appendix: Physicochemical consideration of gallstone formation.** *Ibid* 162–5.—The streaming potential decreases in the order $^1/_4$ $K_4Fe(CN)_6$, $^1/_3$ $K_3Fe(CN)_6$, $^1/_2$ K_2SO_4 and KCl, as well as I, Br, Cl, combined with either Na or K. An increase in the Ca content of bile may be expected to decrease the stability of the cholesterol sol. C. T. S

Studies in carbohydrate metabolism. II. Glucose-lactic acid cycle in diabetes. HAROLD E. HIMWICH, WM. H. CHAMBERS, Y. D. KOSKOFF AND L. H. NAHUM. *J. Biol. Chem.* **90**, 417–26(1931); cf. *C. A.* **23**, 4729; **24**, 1412.—Analyses for lactic acid and glucose contents of the blood of depancreatized and of phlorizinized dogs indicate that

during exercise, and also in rest, the muscle adds lactic acid to the blood and removes hexose from it, while the liver acts reciprocally. In resting depancreatized dogs the muscle adds approx. 8 mg. % of lactic acid to the blood and removes 17 mg. % of hexose; the liver removes 10 mg. % of lactic acid and adds 23 mg. % hexose. Correction for the loss in the lymph and comparison of equal vols. of blood show that the liver absorbs the whole of the lactic acid added by the muscle, but the muscle in return absorbs only 13 mg. % of the total 21 mg. % of hexose added by the liver. Most of the remaining hexose is lost in the urine. The interdependence of muscle and liver in muscular activity and recovery, both in normal and diabetic animals, is emphasized. K. V. THIMANN

The acid-base equilibrium of the blood in pathological conditions. I. Changes observed in the toxemias of pregnancy. EDWARD MUNTWYLER, NATALIE LIMBACH, ARTHUR H. BILL AND VICTOR C. MYERS. *J. Biol. Chem.* 90, 607 17(1931).—In 26 cases of toxemias of pregnancy a lowering of the alk. reserve of the plasma, similar to that of normal pregnancy, was observed. There was a corresponding decrease in total base from 153.8 to 144.7 millimols. per l. (cf. Oard and Peters, *C. A.* 23, 2469). The bicarbonate increased considerably *post partum*, and in many cases also the total base. The lowering of alk. reserve is ascribed to hyperventilation. K. V. THIMANN

Glucemic curve in malignant tumors, before and after surgical treatment and radium therapy. G. CERUTI AND F. BENSO. *Arch. ital. chir.* 27, 82–94(1930); *J. Am. Med. Assoc.* 96, 149.—Ten days after surgical intervention and after radium therapy there was an approach and later an actual return to the normal values of the glucemic curve. R. C. WILLSON

Calcium, magnesium, potassium, sodium and chlorine in blood after cranial injuries. G. SICILIANI. *Arch. ital. chir.* 27, 95(1930); *J. Am. Med. Assoc.* 96, 149.—Cranial injuries more or less grave (commotio, fracture of the base) cause a const. but transitory disturbance, for not more than 36 hrs., of the electrolytic equil., characterized by a diminution in Ca and an increase in K and P, while the remaining electrolytes behave in an inconst. manner. These changes were more pronounced when the trauma affected the area of the base of the cranium. R. C. WILLSON

H—PHARMACOLOGY

A. N. RICHARDS

Use of 7% carbon dioxide and 93% oxygen in the treatment of carbon monoxide poisoning. C. K. DRINKER AND J. SHAUGHNESSY. *J. Ind. Hyg.* 11, 301–14(1929).—The treatment of persons suffering from acute CO poisoning is best carried out by the inhalation during the first 5 to 20 min. of mixts. contg. 7% of CO_2 and 93% of O_2, followed by the usual mixt. contg. 5% of CO_2 and 95% of O_2. B. C. A.

Solution of dextrose and sodium chloride for obliterating varicose veins. HOWARD M. KERN. *Ann. Surgery* 93, 697 706(1931).—A study of 464 cases in which an equal mixt. of 50% dextrose and 30% NaCl solns. was used almost exclusively. R. B.

The action of gold preparations in tuberculosis. FRANZ WIRZ. *Z. Tuberk.* 65, 489 91(1930).—The author used Aurophos and Lopion in two cases of skin tuberculides originating hematogenously, and there resulted new lesions from this Au treatment. It is, therefore, concluded that the Au prepns. are not parasitotropic, and it is suggested that the chemical industries seek new combinatons to overcome this deficiency. H. J. CORPER

An attempt to use leucocytes as a mechanical vehicle for transporting therapeutic agents to the lungs. PHILIPP SPANIER. *Beitr. klin. Tuberk.* 73, 210–31(1929).—S. verified the observations of Christeller and Eisner that heterogeneous living leucocytes introduced into the blood stream of an animal mostly are retained in the pulmonary capillary while they pass the capillaries of all the other organs. This idea is utilized for transporting therapeutic agents. The leucocytes were obtained from dogs in which sterile turpentine oil abscesses were produced. The substances to be phagocyted were introduced either *in vivo* by injecting into a 3-day old abscess and removing the pus one-quarter hr. after introduction or *in vitro* by shaking the leucocytes at 37° with an equal vol. of isotonic soln. prepd. in 0.85% NaCl and 1.5% Na citrate used in equal amts. The suspension was given in 1 cc. amts. to rabbits or dogs intravenously. In these expts. trypan blue, iron prepns., I and contrast media such as $BaSO_4$ were utilized. H. J. CORPER

Benzene-oil treatment in tuberculosis. JONAS KAIRIUKSTIS. *Beitr. klin. Tuberk.* 73, 456–9(1930).—The author used a 30% sterile soln. of benzene in olive oil by intramuscular injection in amts. of 0.1 to 0.2 cc. This caused a focal reaction in tuberculous individuals which resulted in a favorable action upon the course of the disease. The

results in surgical tuberculosis appeared to be better than those in pulmonary tuberculosis. The clinical data are given in summarized form. H. J. CORPER

Therapeutic experiments with ascaridole. JOHANNES ZSCHUCKE. *Arch. Schiffs-Tropen-Hyg.* **34**, 472–80(1930).—Good results are reported in the treatment of *Necator* and *Ascaris* infections. H. EAGLE

The treatment of children's dysentery with Rivanol. D. TEITEL. *Arch. Schiffs-Tropen-Hyg.* **34**, 481–6(1930).—Rivanol taken in the mouth in doses of 5 mg. 3–6 times daily has a marked therapeutic effect upon amebic dysentery. If unsuccessful after 5–7 days, it should be supplemented by 2–3 injections of emetin. H. EAGLE

The treatment of surra with benzenearsonic acid "Höchst 4002." OTTO NIESCHULZ AND F. K. WAWO-ROENTOE. *Arch. Schiffs-Tropen-Hyg.* **34**, 662–9(1930).—Unsatisfactory results were obtained in the treatment of experimentally inoculated rats, mice and guinea pigs. H. EAGLE

The chemotherapeutic effect of gold compounds upon mice inoculated with Spirochaeta crocidurae, with particular reference to treatment with mixtures of neoarsphenamine and Solganal. W. MENK. *Arch. Schiffs-Tropen-Hyg.* **35**, 97–107(1931).—Solganal is much more effective than neoarsphenamine as a sterilizing agent in inoculated mice. M. recommends the use of a mixt. of the 2 in the treatment of recurrent fever and suggests a possible application in the treatment of syphilis. H. E.

Cholosulin. L. R. GROTE. *Arch. Verdauungskrankh.* **48**, 1–24(1930).—Cholosulin (an addn. compd. of insulin with the Na salt of desoxycholic acid) is supposed to be an insulin which can be taken by mouth. G. found it effective in only 2 out of 16 cases of diabetes. H. EAGLE

Can the retention of foods in the human stomach be affected by the administration of various kinds of beer or of their carbon dioxide and bitter contents? A. BICKEL AND F. FLEISCHER. *Arch. Verdauungskrankh.* **48**, 28–42(1930).—Beers cause a delayed emptying time of the stomach because of their alc. content, rather than their CO_2 or bitters contents. H. EAGLE

The effect of ephedrine upon gastro-intestinal activity. F. TRAKHTENBERG. *Arch. Verdauungskrankh.* **48**, 69–95(1930).—Ephedrine inhibits the motility of the stomach and intestines for 3–4 hrs., preceded by a short period of excitation (8–10 min.). The gastric acidity is unaffected, but the total Cl^- is increased. Its therapeutic use is indicated in gastric or duodenal ulcer, gastric hypertonicity and hypermotility, spastic obstipation, etc. H. EAGLE

The insulin-sensitivity of nondiabetic humans and its relationship to the vegetative nervous system. ERNST STAMM. *Arch. Verdauungs-Krankh.* **48**, 104–24(1930).—The intravenous injection of $^1/_{10}$ unit of insulin into normal subjects causes a maximal fall in blood sugar of 26.5 mg. %. In vagotonic subjects, this may be as high as 45.6 mg. %, in hypothyroidism it averages 47.2 mg %. On the other hand, in subjects with increased sympathetic tone (*e. g.*, with hyperthyroidism) there is less sensitivity to insulin with an av. fall of only 16.9 mg. % under the same conditions. H. EAGLE

The ingestion of vinegar and lemon juice in their relationship to the morphological character of the blood. ADOLF BICKEL AND GERHARD LISS. *Arch. Verdauungs-Krankh.* **48**, 158–66(1930); cf. *C. A.* **24**, 2169.—Continued ingestion has no harmful effect upon the blood picture. H. EAGLE

Excretion of alcohol in gastric juice following the rectal administration of alcohol. ARTHUR LUKAS. *Arch. Verdauungs-Krankh.* **48**, 332–45(1930). H. EAGLE

Histamine. ANTON KÜPPER. *Klin. Wochschr.* **9**, 2137–40(1930); cf. *C. A.* **24**, 5378.—The possible role of histamine in intestinal intoxication is discussed. As little as $^1/_2$ mg. injected subcutaneously into humans causes an increased secretion of gastric juice contg. both acid and pepsin. Intravenous injection is effective only if it is given very slowly. In approx. $^1/_2$ the cases which are diagnosed as achylia gastrica, histamine causes an active gastric secretion. It is to be emphasized that a pos. histamine test does not exclude organic gastric lesions, notably cancer; nor does an absence of secretion mean irreparable anatomical damage. This stimulating action of histamine upon gastric secretion is due to a direct action on the secreting cells. Histamine is found in all tissues, and in very high concn. in the lungs, presumably as an intermediary product of metabolism. The close similarity between anaphylactic shock and the pharmacological effects of histamine suggests the etiological role of the latter. H. EAGLE

Chemistry of uroselectan. A. BINZ AND C. RÄTH. *Klin. Wochschr.* **9**, 2297–8(1930).—2-Pyridone-5-arsonic acid was found to be less toxic than any known org linkage of As, in particular, the arsonic acids of the benzene ring. I introduced instead of the arsonic acid also resulted in a compd. of very slight toxicity; its Na salt was intro-

duced in 1927 as a therapeutic agent ("Selectan") in the treatment of streptococcal mastitis in cows. The Na salt of 1,2-dihydro-5-iodo-2-keto-1-pyridineacetic acid is uroselectan, sol. up to 35%, the lethal dose of which is 3.37 g. per kg. when injected intravenously into the rat. H. EAGLE

Cholesterol and lecithin in the water and acid-base economy. RUDOLF DEGKWITZ. *Klin. Wochschr.* 9, 2336–44(1930).—Cholesterol and lecithin have antagonistic and mutually neutralizing effects upon the hemolysis of red cells by water, acid or alkali. In general, cholesterol increases the resistance of the cell, possibly because, being a hydrophobic substance, it promotes a protoplasmic change in the nature of a water-in-oil dispersion, in which effect it would be, and is, aided by Ca^{++} and Mg^{++}. Lecithin, on the other hand, being hydrophilic, might promote an oil-in-water dispersion, which would be aided by Na^+ and K^+. Cholesterol injected into rabbits causes a transport of H_2O and Cl^- from the tissues into the blood and urine, with polyuria, and very high blood and urine $[Cl]^-$. Hyperlecithinemia, on the other hand, causes a low plasma and urine $[Cl]^-$, and a retention of H_2O and Cl^- in the tissues. Paradoxically, the prolonged peroral administration of cholesterol causes water and Cl^- retention, and decreased urinary excretion. H. EAGLE

The effect on the experimental animal of injection of a liver extract, prepared according to the method of Gänselen. W. EDERLE AND H. KRIECH. *Klin. Wochschr.* 10, 25–6(1931).—The ext. had a very favorable effect in white rats with a *Bartonella* anemia, whose spleen had been removed. H. EAGLE

Relationships between insulin and adrenaline in the human organism. BERNHARD KUGLEMANN. *Klin. Wochschr.* 10, 59–62(1931).—If the blood sugar falls below 60 mg. % following the intravenous injection of insulin, there is a considerable rise in systolic pressure and fall in diastolic pressure, the pulse pressure being doubled or even tripled. As the blood sugar returns to normal, there is a concomitant return of blood pressure to normal values. The administration of glucose prevents the blood pressure change, which is only observed if the blood sugar falls below 60 mg. %. Simultaneous with the rise in pressure there is a moderate leucocytosis, with a particular rise in lymphocytes; and, in patients with an enlarged spleen, there is a marked decrease in its size. Since all three of these phenomena (blood pressure, blood count and splenic changes) are observed following the injection of adrenaline, K. concludes that in insulin hypoglucemia there is a mobilization of adrenaline as a compensatory factor, tending to restore the blood glucose to its normal values. H. EAGLE

Adenosinephosphoric acid and cardiac activity. A contribution to the component of muscle extract which affects the heart. HANS ROTHMANN. *Klin. Wochschr.* 10, 67(1931). —Adenosinephosphoric acid causes slowing of the heart rate, and induces a more regular and stronger action in pathological conditions. Since it can be demonstrated in muscle exts., it is concluded that it is the active constituent in such exts. as regards cardiac function. H. EAGLE

The analysis of the action current curve of the heart into chemical phases. I. Relation between the action current and the formation of lactic acid. RUDOLF SIEGEL AND Z. UNNA. *Klin. Wochschr.* 10, 72–3(1931).—Monoiodoacetic acid is known to prevent the formation of lactic acid in striated muscle. In mice and rabbits small doses cause a change and broadening of the *T*-wave of the electrocardiogram while larger doses cause its complete disappearance without affecting the *Q R S* complex. S. and V. suggest that the *T*-wave and the formation of lactic acid are due to the same process; moreover, that the formation of lactic acid begins 0.05 sec. after the beginning of contraction (*Q R S* complex) and continues through systole. **II. Contractions without after-waves in the electrocardiogram.** *Ibid* 171.—After poisoning with CH_3ICO_2H, the ventricles continue to contract despite the absence of the *T*-wave in the electrocardiogram. H. EAGLE

The excretion curve of iodine from the blood following the administration of sodium tetraiodophenolphthalein under normal and pathological conditions in the animal experiment. H. EITEL AND A. LOSSER. *Klin. Wochschr.* 10, 109–11(1931). H. E.

The locally limited action of hormones, particularly that of pituitrin, upon the water exchange. ARISTID KISS. *Klin. Wochschr.* 10, 162–5(1931).—Pituitrin has an effect upon the connective tissue of the skin, causing an increased water absorption. The degree of its effect depends upon the conditions of the skin, which is apparently under the control of the liver. H. EAGLE

Comparative actions of sympathomimetic compounds: Influence of cocaine and certain related compounds upon the actions of a group of sympathomimetic amines. M. L. TAINTER. *Quart. J. Pharm. Pharmacol.* 3, 584–08(1930); cf. *C. A.* 24, 894.—The cocaine sensitization-desensitization was applied to a group of sympathomimetic

amines. Dihydroxyphenylethylamine and dihydroxyphenylpropylamine were sensitized by cocaine and reversed by ergotoxine, and thus were sympathicotropic, in common with the other catechols hitherto studied. The substitution of nitro, chloro or carbethoxy groups in the para position of phenylethylamine or the replacement of the Ph by a thiophene group produced pressor compds. which were desensitized by cocaine, and hence were pseudo-sympathicotropic. *p*-Carboxyphenylethylamine, Ph_3EtN and "salvamin," a trihydroxy product, were inactive on blood pressure. Psicaine, benzoylpseudotropeine (tropacocaine) and *β*-eucaine, which are closely related to cocaine chemically, did not reproduce the cocaine sensitization-desensitization. Cyanides, by interfering with the oxidative processes, depressed the response to adrenaline, tyramine and pituitary equally, and therefore did not resemble the cocaine action. Also, smooth muscle depression sufficient to lower the blood pressure, from large doses of papaverine, did not depress the action of these pressor drugs. It therefore seems unlikely that interference with oxidative processes or smooth muscle depression can be essentially involved in the phenomena. Cocaine increased the hyperglucemic responses of rabbits to adrenaline, and decreased those to ephedrine. The typical cocaine sensitization-desensitization phenomena can, therefore, be seen in functions not involving a smooth muscle response. W. O. E.

An unsuccessful abortion attempt or suicide by means of arsenic. A. SARTORI. *Chem.-Ztg.* 55, 105–6(1931).—Investigation into the death of a pregnant woman at first presented a picture of ergot poisoning. Later a bag contg. a gray powder was found. Analysis showed powd. C and As_2O_3. RUSSELL C. ERB

Effect of various concentrations of nicotine in tobacco on the growth and development of fowls. J. E. HUNTER AND D. E. HALEY. Penna. Agr. Expt. Sta., *Bull.* 258, 9(1930); Abstract; *43d Annual Report of the Director.*—When a high nicotine strain of tobacco is used in the feed of chicks, remarkably large amts. of nicotine can be tolerated. By building up a tolerance to tobacco in baby chicks, as much as 1.2% of pulverized tobacco can be included in the ration without noticeable injury. In fact there appears to be a stimulation due to the tobacco and better growth gains are made than by the controls. It is believed that continuous tobacco treatment will effectively control *worm infestation.* C. R. FELLERS

Pharmacological action of irradiated proteins and protein derivatives. P. HOLTZ *Arch. ges. Physiol.* (*Pflügers*) 226, 559–77(1931).—Serum irradiated with ultra-violet light has a dilator action on the blood vessels of the frog. Irradiated euglobulin, glycine, leucine, histidine and tyrosine show the same action. The action of the irradiated serum is attributed to HCNO, AcH and imidazole derivs., whose presence in such serum was demonstrated. The stimulating effect of irradiated sera on the intestine was similarly attributed to the presence of histamine or another imidazole deriv. A. G.

The effect of irradiated serum on sugar elimination by the isolated liver of warm-blooded animals. P. HOLTZ. *Arch. ges. Physiol.* (*Pflügers*) 226, 578–84(1931).—Irradiated serum markedly affects sugar elimination by the liver of guinea pigs, cats and dogs. In most cases the elimination is reduced. ARTHUR GROLLMAN

The changes in the stimulation time-tension curves by narcosis, cold and veratrine. CHUNG LIEN HOU. *Arch. ges. Physiol.* (*Pflügers*) 226, 676–88(1931). A. G.

Mode of action of compounds of insulin with bile acids on subcutaneous administration. R. STEPHAN. *Deut. med. Wochschr.* 56, 88–91(1930).—Sodium desoxycholate, coupled with insulin, shows the same action when administered subcutaneously as after oral administration. The clinical action of the combination is, however, different from that of insulin. ARTHUR GROLLMAN

The present status of chemotherapy, particularly in the treatment of tropical diseases. C. SCHILLING. *Deut. med. Wochschr.* 56, 955–8(1930).—An address dealing with the modern trend of chemotherapeutic research. ARTHUR GROLLMAN

Cholosulin and the daily blood sugar curve. RICHARD KÜHN. *Deut. med. Wochschr* 56, 1341–2(1930).—Cholosulin, a combination of insulin and the Na salt of desoxycholic acid, produced no change in the blood sugar curves of diabetics. A. G.

The initial insulin hyperglucemia. A. v. KORÁNYI. *Deut. med. Wochschr.* 56, 1683(1930).—The initial hyperglucemia which follows the injection of insulin is attributed to a demobilization of sugar in response to the rapid depletion of the sugar in the muscles. ARTHUR GROLLMAN.

The effect of soporifics on the basal metabolism in Basedow's disease. A. BORNSTEIN. *Deut. med. Wochschr.* 56, 1861–2(1930).—The increased metabolism in thyroid toxicoses is due to nervous stimulation and to an increased metabolic activity on the part of the cells. The former fraction of the metabolic increase is abolished by the use of soporifics; the latter remains unaffected. ARTHUR GROLLMAN

Is lactic acid absorbed through the skin? E. E. BAUER. *Deut. med. Wochschr.* **56**, 1869–70(1930).—No evidence is available to indicate that lactic acid or other nutrients may be absorbed through the skin. ARTHUR GROLLMAN

Distribution between blood plasma and red blood corpuscles of some substances used in therapeutics. R. FABRE. *Bull. soc. chim. biol.* 12, 954–64(1930); cf. *C. A.* **25**, 1591.—In dog blood, diethylmalonylurea and allylisopropylmalonylurea showed a distribution between red corpuscles and plasma of 6 mg.:3.6 mg. and 19.1 mg.:1.93 mg., resp., per 100 g. blood. Quinine and hydrastine were about equally distributed between corpuscles and plasma but were retained longer by corpuscles. C. G. KING

Pharmacological influence of the substitution of a methyl group in the β-carbon of methylaminomethyl(*p*-hydroxyphenyl)carbinol. RAYMOND-HAMET. *Compt. rend.* **192**, 450–2(1931).—The action of methylaminomethyl(*p*-hydroxyphenyl)carbinol has been studied in double suprarenalectomized dogs which have been treated with cocaine or yohimbine. Its action has been compared with that of *p*-hydroxyephedrine and ephedrine. The substitution of a methyl group in the β-position has endowed the drug with an adrenaline-like action, which it lacked. G. H. W. LUCAS

Investigation on the pharmacological action of the vessels of the pigeon's wing. I. The influence of the changes in concentration of sodium, calcium and potassium chlorides, as well as in the hydrogen-ion concentration in the perfusing Ringer solution. TOMONORI MANABE. *Folia Pharmacol. Japon.* 11, 225–37; Breviaria 17(1931).—The vessels in the pigeon's wing were perfused with Ringer soln. in which the chloride content and p_H were varied. Excess NaCl increases persistently the discharged quantity but a large excess causes a decrease. The vessels are dilated and the osmotic pressure is increased. The decrease in flow is due to a swelling of the endothelium in the small vessels, especially the capillaries. The tissues also are affected. The addn. of $CaCl_2$ causes a dilation of the vessels with small amts. and a constriction with larger quantities. Absence of $CaCl_2$ in Ringer soln. produces a dilation. The addn. of KCl produces a dilation or a constriction, depending on the quantity. Alk. Ringer soln. causes a dilation, as does a highly acid one. G. H. W. LUCAS

The experimental investigation of Panax ginseng. IV. The virulence of some nerve poisons and the poison phenomena brought about in rats fed on Panax ginseng. PIUNGKI MIN. *Folia Pharmacol. Japon.* 11, 238–55; Breviaria 18(1931); cf. *C. A.* **24**, 5869.—The nerve poisons adrenaline, physostigmine and pilocarpine act synergistically, while atropine and adrenaline act antagonistically in ginseng-fed rats. **V. The comparative study on the chemical constituents and the general action of Panax ginseng and Panax quinquefolius.** *Ibid* 256–60; Breviaria 19(1931).—The chief constituents of each plant were quantitatively prepd. Panax ginseng contains more panacene, panax acid, phytosterol and glucoside than *Panax quinquefolius*. Alc. exts. of both plants injected into mice produced tail symptoms (the tail being carried erect), convulsions and death. Panax gensing exts. were more potent. G. H. W. LUCAS

The antiphlogistic action of drugs on inflammation produced by streptococci. HIROSHI SUZUKI. *Folia Pharmacol. Japon.* 11, 276–86, 287–98; Breviaria 20–1(1931); cf. *C. A.* **25**, 740.—Antipyrine, quinine, erycon, salicylic acid, sinomenine, casein, rabbit serum, streptococcus serum and streptococcus vaccine exert an antiphlogistic action on the inflammation produced by streptococci-salt soln. in the rabbit eye. The action of antipyrine, quinine, erycon and sinomenine on inflammation produced by streptococci is weak, while that of salicylic acid, casein, rabbit serum and staphylococcus is scarcely antiphlogistic. The action of the drugs is stronger on the inflammation produced by streptococci than on that produced by chem. or phys. stimulation. Drugs act but slightly on the inflammation produced by cold in the rabbit eye. G. H. W. LUCAS

The pharmacology of benzoylglucuronic acid. SHINZO SAKATA. *Folia Pharmacol. Japon.* 11, 299–324; Breviaria 21–2(1931).—Warm-blooded animals are protected from poisoning by chloral hydrate, camphor, phenol, naphthol, borneol, antipyretica and morphine by the formation of a conjugated compd. with the glucuronic acid in the body. The conjugated glucuronic acid in the urine is thus increased. The conjugated acid belongs to the glucoside type, whereas the benzoyl derivs. are of the ester type. Phenylglucuronic acid, urochloralic acid and the conjugated ester type await investigation. The action of benzoylglucuronic acid was measured on rabbits and toads. On the hearts of these, tonus is increased and contraction height decreased by small doses; large doses cause a fall in tonus. The rate is unchanged and the heart stops in diastole. The action appears on the muscle itself. In small doses the drug causes a dilation of vessels in the rabbit ear and in the frog extremities. In large doses a constriction follows. It has some diuretic action in rabbits and toads; kidney vessels are dilated. A transient hydremia follows its administration. The diuretic action

is present in the toad after the ligature of the kidney portal vessels. Small doses stimulate and toxic doses paralyze isolated rabbit organs. G. H. W. LUCAS

A contribution on the pharmacology of phenylpyroracemic acid. TADASHI ISEKI AND HIROTO MATSUSHIMA. *Folia Pharmacol. Japon.* 11, 261–75; Breviaria 20(1931).—Various amino acids and their intermediate metabolic products possess some influence on certain hormone actions in animal organs. The intermediate product of phenylalanine, phenylpyroracemic acid, was studied. On perfused toad livers, it increased sugar. It produced no action on the pupil. On the surviving rabbit intestine it had a depressing action. On subcutaneous injection into rabbits, it increased blood sugar and was not synergistic with adrenaline. On the isolated hearts of toads and rabbits it had a paralyzing effect, its action being on the muscle itself. G. H. W. LUCAS

The relationship between the action of some cardiac tonics on the embryonic chicken heart and its stage of development. SAKURO KIRILARA. *Folia Pharmacol. Japon.* 11, 325–33; Breviaria 22–3(1931).—The action of coramine, digitalein, cardiazole and adonidin on 2 to 10 day old chicken embryo heart has been followed. A 2 day old embryo is stimulated by these heart tonics. The sensitivity increases up to max. where it remains unchanged for about 10 days. The action of these drugs on the stage of development was also studied. G. H. W. LUCAS

The influence of various conditions on the resorption of sodium salicylate from the pleural cavity as well as on the manner of resorption of these drugs. II. MASAYOSHI OGAWA. *Folia Pharmacol. Japon.* 11, 334–45; Breviaria 23(1931); cf. *C. A.* 25, 1286 The right lung was inflamed with $AgNO_3$. 0.1 g. Na salicylate per kg was injected in the pleural cavity and the rate of resorption followed. Relatively slight inflammation resulted in good absorption, but marked inflammation slowed up the rate on account of damage of the capillaries. Respiratory movements facilitated resorption. Secretion of exudate following damage to vessels lowers the concn. of the applied material **III.** *Ibid* 346–58; Breviaria 24–5.—The lungs were treated in the normal and in an inflamed condition, and the blood in the lung veins was examd. for Na salicylate. Low-grade inflammation assists resorption, whereas high-grade hinders it A closed pneumothorax hinders resorption The disturbance in resorption is more marked in the pleura pulmonalis than in the pleura parietalis G. H. W. LUCAS

The relationship between the vomiting-, blood-sugar- and uric-acid-regulating centers from a pharmacological standpoint. II. The influence of emetica on the uric acid excretion. MOKKIU MUN. *Folia Pharmacol. Japon* 11, 359–69; Breviaria 25 (1931); cf. *C. A.* 25, 1284. Comparative expts. were performed by injecting dogs subcutaneously with emetica and following the uric acid excretion. Morphine-HCl was used as a control. Following the injection of apomorphine-HCl, emetine-HCl, wine of Sb, $CuSO_4$ and erycon the uric acid excretion was increased over the control Na salicylate and antipyrine lowered the temp. and blood sugar stimulated vomiting and promoted the formation of uric acid. The centers regulating vomiting, blood sugar and uric acid are in close relationship with each other. G. H. W. LUCAS

Effects of insulin and adrenaline on the blood acetone in fasting children. LEIF SALOMONSEN. *Am. J. Diseases Children* 40, 718–24(1930). The antiketogenic action of insulin appears to be secondary to the influence of insulin on sugar metabolism. The administration of insulin to children whose blood sugar has been reduced by fasting reduces the concn. of acetone in the blood, the reduction being less marked the lower the sugar concn. The administration of adrenaline increases the concn. of acetone, the increase being more marked the lower the concn. of blood sugar. The injection of adrenaline is usually followed by an increase in the fatty acid content of the blood E. R. MAIN

The effect of phosphorus in rickets. I. Röntgenologic changes in rickets following administration of phosphorus. EDWARD L. COMPERE. *Am. J. Diseases Children* 40, 941–67(1930).—The administration of a combination of small quantities of elementary P and cod-liver oil to infants with severe cases of rickets has a much greater therapeutic effect than cod-liver oil alone. The administration of P alone is not sufficient to cause the healing of severe cases of rickets. The studies were made during the late fall and winter months. **II. The chemical changes in the blood in rickets following administration of phosphorus.** *Ibid* 1177–92.—The administration of a combination of cod-liver oil and P is followed by a marked increase in the Ca and P contents of the blood serum and in the product of the two. The administration of cod-liver oil alone to infants with severe rickets is followed by a slow but definite increase in the product of the Ca and P contents. The administration of P alone causes no significant changes in the Ca or P contents or in the product of the two. The healing of rickets does not appear to be assocd. with changes in the p_H of the blood serum. E. R. M.

Coffee as an intestinal disinfectant. Ernst G. Dresel and Harald Lotze. *Arch. Hyg.* **104**, 144–55(1930).—Broth infusions of finely ground coffee or prepns. from which the caffeine has been removed do not permit the growth of typhus bacilli or cholera vibrio; they inhibit the growth of Flexner bacilli and kill Shiga-Kruse bacilli. Finely ground coffee appears to be a more effective agent in its action against the pathogenic microörganisms of the intestinal tract than the com. prepns. of C.
E. R. Main

The blood in experimental benzine poisoning. L. P. Bryullova, A. S. Brussilovskaya, N. V. Lazarev, M. P. Lyubimova and D. I. Stalskaya *Arch. Hyg.* **104**, 226–38(1930).—No marked or characteristic chem. or histologic changes appear in the blood of lab. animals poisoned with benzine vapor. E. R. Main

Paths of absorption and excretion of sodium tetraiodophenolphthalein. A. J. Delario. *J. Lab. Clin. Med.* **16**, 329–40(1931).—Na tetraiodophenolphthalein appears to be absorbed by both the small and large intestines following oral or rectal administration to dogs. It leaves the blood within 2 to 4 hrs. after intravenous administration. The liver excretes from 60 to 70% of the dye, apparently unchanged; the large intestine about 25%. From 5 to 10% is eliminated in the urine partly in an inorg. state. Some of the dye may be rendered insol. by contact with pancreatic juice or fat present in the small intestine. The results are based upon the detn of I after oxidation of the blood, urine, etc. E. R. Main

The effect of calcium-precipitating substances on the ciliated epithelium of the maxillary sinus. W. F. Wenner. *J. Lab. Clin. Med.* **16**, 341–6(1931).—The movement of the cilia of the excised fragments of ciliated epithelium of the maxillary sinuses of rats and rabbits ceases when alizarin, citrate or oxalate solns. are added to the medium in which the tissues are immersed. E. R. Main

Some effects of amytal anesthesia. J. M. Olmsted and George Giragossintz. *J. Lab. Clin. Med.* **16**, 354–61(1931); cf. *C. A.* **25**, 140. The intravenous injection of amytal into dogs is not followed by an increase in the blood sugar content of dogs that have been fed a diet of lean meat. A slight increase may follow if the dogs have been fed a diet rich in carbohydrates. The hyperglucemia which accompanies the administration of morphine is prevented when amytal is injected simultaneously with the morphine. The increase in blood sugar that normally follows a short period of asphyxia is prevented by amytal. In man, the non-protein N and urea contents of the blood are markedly increased, the blood pressure is reduced and the heart rate increased after the administration of amytal. The gastric secretion of dogs is inhibited during amytal anesthesia. E. R. Main

The glucemic reaction with minimum quantities of adrenaline administered intravenously. L. Cannavo. *Boll. soc. ital. biol. sper.* **5**, 810–3(1930).—Small variable doses of adrenaline were injected intravenously into normal persons, and into patients afflicted with various diseases. The results showed that the glucemic effect of insulin is variable and is connected with the constitutional state of the subject and the sympathetic-parasympathetic equil. In some individuals there was a fall in blood sugar 5 min. after the injection and then a rise. Adrenaline, when injected intravenously, may cause appreciable changes in the glucemic titer in doses as low as 1/400 mg. Patients with hepatic lesions showed no noticeable difference to the action of adrenaline in contrast to normal or to patients affected with other diseases. Peter Masucci

Qualitative and quantitative studies on the penetration of the lungs by atomized drugs. Pompeo Spoto. *Boll. soc. ital. biol. sper.* **5**, 815–7(1930).—A method is described for studying the penetration of atomized drugs in the lungs of the dog. The substances tested were methylene blue, iodized oil colored with Sudan III, and colloidal Ag. From the results obtained, it is shown that the penetration of atomized liquids does occur if the mouth is kept open and the nares are closed; the atomized liquids may reach the alveoli of the lungs but only in small amts. and so unequally distributed that parts of the lung are not reached. Peter Masucci

Quantitative studies on the fixing power of the hepatic reticulo-endothelium apparatus. G. Orestano. *Boll. soc. ital. biol. sper.* **5**, 818–9(1930).—Colloidal Ag_2S was injected intravenously into rabbits. After different intervals of time the animals were killed and the Ag fixed by the liver was detd. After 9 min. 1/4 of the Ag injected was found in the liver. With longer intervals after injection, the velocity of fixation diminished; 1/4 was fixed in 2 hrs. and about 1/2 after 8 to 10 hrs. PbS gave similar results; after 2 hrs. 1/2 of the Pb was found in the liver. Peter Masucci

The relation between the action on the hemopoietic tissue and fixation of colloidal copper sulfide in the reticulo-endothelial apparatus. Gerlando Lo Cascio. *Boll. soc. ital. biol. sper.* **5**, 819–22(1930).—The injection of 10 cc. of an 0.8% soln. of col-

loidal CuS into rabbits resulted in the presence of 23,000 nucleated erythrocytes in 24 hrs. If, however, the injection of CuS is preceded by the injection of HgS (0.3 to 1 cc. of 1% soln.) the erythroblastic reaction diminished in proportion to the HgS injected. India ink and lithiocarmine gave similar results but HgS was the substance which produced the most complete, permanent and innocuous block of the reticulo-endothelial app. of the bone marrow, spleen and liver. PETER MASUCCI

The action of quinine on the reticulo-endothelial system. A. LEVI AND E. BELLODI. *Boll. soc. ital. biol. sper.* 5, 857–8(1930); cf. *C. A.* 24, 2176.—Quinine in relatively high doses (1–2 mg.) inhibits the development of the reticulo-endothelial system in mice; in smaller doses, (0.5 mg.) equal to those used in inhibiting the development of tumors, it stimulates the growth of this system. PETER MASUCCI

The resistance of the corpuscles after using antipyretics. A. LEVI AND R. BASSI. *Boll. soc. ital. biol. sper.* 5, 859–60(1930).—The repeated administration to rabbits of antipyretics (antipyrine, pyramidone, melubrin, cryogenin, maretin) in therapeutic doses (0.50 g.) does not give rise to variations in the resistance of the corpuscles and does not cause hemolysis. Toxic or mortal doses do exert a slight change in resistance. The above antipyretics may, therefore, be satisfactorily used in therapy. P. M.

The neuromuscular junction in curarized frogs and in frogs treated with quinine. G. M. PICCININI AND C. DELFINI. *Boll. soc. ital. biol. sper.* 5, 861 2(1930).—The gastrocnemius of the normal, of the curarized and of the quinine-treated frog when examd microscopically showed no sp. changes in the terminal motor app. P. M

The pharmacodynamic posology of quinine for frogs and the course of the spontaneous and reflex motility. G. M. PICCINNI AND C. DELFINI. *Boll. soc. ital. biol sper.* 5, 862-6(1930). Quinine-HCl.$2H_2O$ was injected into the dorsal lymph sac of (*1*) hibernating and (*2*) summer *Ranae esculentae*. Doses of 0.10, 0.08, 0.05, 0.03 g in weak solns. (1:300, 1:500, 1:1000) injected into frogs of 40, 30, 20, 12 g. were all lethal. The m. l. d. was 0.25 mg. per g. of frog. All the lethal doses produced a depression followed by a general paralysis. Under these conditions weak elec. stimuli applied to the skin contracted the muscles energetically. The reflex motility gradually decreased but lasted up to 24 hrs. Doses approaching the m. l. d. (0.2 to 0.07 mg.) produced the same toxic symptoms which were often preceded by a transitory excitation. The frogs were only apparently dead but within 24 hrs. became normal again. Moderate doses (0.06–0.04 mg.) always produced excitation phenomena of varying duration and intensity. Sub-specific doses of 0.0061–0.04 mg. showed nothing definite but did increase muscular work. The effects of injecting concd. solns. were also investigated and are discussed PETER MASUCCI

The action of insulin on the muscle contraction of the frog. G. BUCCIARDI AND A. DE NIEDERHÄUSERN. *Boll. soc. ital. biol. sper.* 5, 870 2(1930). Insulin injected into the frog causes an increase in the amplitude of muscle contractions and muscular work. The increase in the capacity for work coincides with a diminution of muscular glycogen. Insulin convulsions cause a diminution of muscle glycogen and a decrease in muscular work. PETER MASUCCI

Experimental studies on the hypoglucemic action of beer yeast administered enterically. AURELIO COSTA. *Boll. soc. ital. biol. sper.* 5, 878–81(1930).—Beer yeast administered in 5-g. doses by stomach tube to rabbits, as a general rule, produced slight hyperglucemia. It did retard, however, the hyperglucemic peak usually obtained when glucose is injected intravenously into rabbits. PETER MASUCCI

The action of insulin on thermoregulation. GIULIO CERUTI AND ENNIO SAPEGNO. *Boll. soc. ital. biol. sper.* 5, 905–6(1930).—Under the action of insulin, if the dose has been insufficient or due to the peculiar condition of resistance of the individual animal the hypoglucemia does not reach below a certain level, the internal temp. does not vary markedly. However, if the dose has been sufficiently large to produce a marked lowering of blood sugar approaching the convulsive dose (0.06–0.05%) then there is a rapid fall of temp. which is related to the glucemic titer. The fall of temp. is arrested by the injection of glucose. The temp. was detd. by a thermocouple method. PETER MASUCCI

The mechanism of action of colloidal sulfur. G. RASTELLI AND A. CASAZZA. *Boll. soc. ital. biol. sper.* 5, 939–42(1930).—Egg albumin and blood serum have the power to transform S into H_2S; the greater the dispersion of the S, the less is the reduction to H_2S. Colloidal S when injected into the circulation exerts a double action. The portion of the S which exists in the true colloidal state dets. the anaphylactic type of shock, while the portion which exists in a state of flocculation and which is present in all preparations, becomes reduced to H_2S which dets. the toxic effect. P. M.

Radium emanations and the physiologic action of certain drugs. P. MASCHERPA

AND G. BELLUZZI. *Boll. soc. ital. biol. sper.* 5, 944–6(1930).—The expts. were made on frogs and mice kept in a closed container into which circulated air that had been bubbled through a soln. of $RaBr_2$. Morphine-HCl was injected into frogs in 0.01 g. doses and into mice in 0.004 g. doses and strychnine sulfate into frogs in 0.00002 g. doses and into mice in 0.00005 g. doses. It was observed that in the animals treated with the Ra emanations the toxic picture brought on by the 2 alkaloids reached greater degrees of violence and appeared much more rapidly than in the control animals. Often the doses administered were lethal to the radioactivated animals. PETER MASUCCI

Biochemistry of magnesium narcosis. EMILIO MARTINI. *Boll. soc. ital. biol. sper.* 5, 946–8(1930).—The narcotic efficiency of Mg salts depends on the alk. reserve of the blood. The higher the alk. reserve, the less is the Mg content, or the greater is the Ca content of blood of the awakened animal. M. makes the deduction that an increase or a diminution of the alk. reserve corresponds to an increase or decrease, resp., of the narcotic efficiency of Mg. PETER MASUCCI

The action of bulbocapnine, injected intravenously on the local reflexes of posture of man. U. DEGIACOMO AND A. SEVERINO. *Boll. soc. ital. biol. sper.* 5, 965–6(1930); cf. *C. A.* 25, 742.—Bulbocapnine injected intravenously into dementia precox and phrenetic patients produced always an initial somnolence phase with a tendency for postural reflexes to become attenuated or to disappear. In the 2nd phase which is of longer duration and more characteristic, and which might be called "the catalexis phase," the postural reflexes are more or less exaggerated. PETER MASUCCI

The hypoglucemic action of "bean tea." G. SORGE. *Boll. soc. ital. biol. sper.* 5, 967–9(1930).—An aq. ext. of the pericarp of beans was made and administered to normal and diabetic subjects. 150 cc. of an infusion from 20 g. of powd. pericarp lowered the blood sugar of fasting normals 15.5–38.6% in 1 hr. and 8.7–26% after 2 hrs. The same dose of infusion given to diabetics under analogous conditions caused a const. lowering of blood sugar, 12–29% after 1 hr. and 20.4–37% after 2 hrs. The same dose administered to normal subjects along with 50 g. glucose *per os* or ½ hr. before the injection of 1 mg. adrenaline produced a const. and marked diminution of sugar and prevented the appearance of hyperglucemia. The exts. may be added to small doses of pancreatic hormone in the treatment of diabetics (synergic action). P. M.

The cure of intestinal lambliasis with naphthalene. G. SORGE. *Boll. soc. ital. biol. sper.* 5, 969–71(1930).—S. found naphthalene a satisfactory therapeutic agent in the treatment of *Lamblia intestinalis*. The administration of 50 cg. per day in 3 capsules, one after each meal for 6–7 days, is recommended. PETER MASUCCI

The influence of acetylcholine on insulinemia. FILIPPO CONDORELLI. *Boll. soc. ital. biol. sper.* 5, 977–9(1930).—C. concludes that insulinemia diminishes after the injection of medium doses of acetylcholine PETER MASUCCI

The inability of the bird organism to condense urea with glyceric acid. G. RUSSO-BIONDI. *Boll. soc. ital. biol. sper.* 5, 980–1(1930).—Neither glyceric acid nor glycerol administered *per os* to chickens or geese caused the slightest increase in the amt. of uric acid excreted, even if simultaneous to the administration of glyceric acid, urea (1–1.5 g.) was injected into the pectoral muscles. The urea injected was found mostly in the excrements, while a small quantity was transformed into NH_3. Therefore, the bird organism does not have the capacity to transform urea into uric acid. P. M.

Relations between glucemia and phosphorus of the blood under the action of uranyl salts and extracts of thyme. MARIANO MESSINI AND ARISTIDE POLI. *Boll. soc. ital. biol. sper.* 5, 982–4(1930).—The injection intravenously of uranyl acetate (0.00012–0.00024 g. equiv. per kg. of rabbit) causes a diminution of the blood phosphates and simultaneously hyperglucemia without glucosuria. This is followed by a second hyperglucemic phase with glucosuria and anuria. The injection of thyme exts. is also followed by a diminution of blood phosphates and hyperglucemia. A lowering of the blood phosphates is apparently followed by an increase in the glucemic titer. P. M.

The behavior of the phosphates and glucose of the blood in normal dogs and in dogs deficient in adrenaline-producing tissue by the action of cold baths. IVAN CIACCIO. *Boll. soc. ital. biol. sper.* 5, 997–1001(1930).—The detns. were made on normal dogs and on dogs from which the suprarenal medulla had been removed. The animals were subjected to a cold bath, 5–7°, for 10–15 min. The results showed that hyperglucemia from cold bears no relation to the hyperfunction of the medulla or to the hypersecretion of adrenaline. There was not always a quant. agreement between glucemia and blood phosphates but in general hyperglucemia coincided with a marked lowering of inorg. P. Instead these showed a behavior analogous to that observed after the administration of glucose. PETER MASUCCI

The behavior of phosphagen and phosphates in muscles after cold baths. GIUSEPPE SOLARINO. *Boll. soc. ital. biol. sper.* 5, 1001–3(1930).—Cold baths caused no variations in the phosphagen or phosphoric acid content of the striated muscles. P. M.

The action of various chemical substances applied directly to the sensomotor cortical centers of the dog. E. MORACCI. *Boll. soc. ital. biol. sper.* 5, 1003–6(1930).—The purpose was to see if any relation exists between the action of certain salts on the sensomotor cortical centers and the position of the relative ions in the Hofmeister series. The salts studied were $(NH_4)_2SO_4$, NH_4Cl, NH_4NO_3, NH_4CNS, K_2SO_4, KCl, KNO_3, KCNS, Na_2SO_4, NaCl, $NaNO_3$, NaCNS, Li_2SO_4, LiCl and $LiNO_3$. In another series, $LiClO_3$, LiI, Li_2CO_3 and Li lactate were studied. The results indicate that the action of the salts on the cortical centers is not a function of the pptg. power of the salts on colloids. With the exception of Li_2CO_3, the Li salts exerted an exciting action, the exciting action of creatine was confirmed. There was an evident analogy between the motor symptoms provoked by Li salts and those induced by creatine. P. M.

The action of certain chemical substances on the motor activity of the intestine. R. DE MARCO. *Boll. soc. ital. biol. sper.* 5, 1006–8(1930).—The motor activity was detd. by observing the length of time a small glass marble took to cross an intestinal loop under normal conditions, and under the influence of adrenaline, atropine, pilocarpine and nicotine. Adrenaline and atropine prolonged the time; pilocarpine caused no changes, while nicotine shortened the time with respect to the normal conditions. PETER MASUCCI

Adrenaline-like substances: their products of oxidation. PIETRO SACCARDI *Boll. soc. ital. biol. sper.* 5, 1010–16(1930).—The substances studied were: $(HO)_2C_6H_3COCH_2NEt_2$ (I) and $HOC_6H_4CH_2CH_2NMe_2$ (II). I was oxidized with Cl_2 water, dried on the water bath, extd. with alc., and the ext. evapd. to dryness (*A*), dissolved in H_2O (10% soln.) and injected subcutaneously into a guinea pig. The urine from the animal was dark, gave all the oxidation reactions analogous to the adrenaline blacks and gave a neg. Thormählen reaction for melanuria, but the Ehrlic diazo reaction was pos. The urine was therefore alcaptonic and not melanotic. The alc. insol. fraction (*B*) if treated with NaOH dissolved, and when injected produced the same phenomena of alcaptonuria. On analysis hydroxyhydroquinone was detected. II when oxidized and treated similar to I did not give rise to indole or pyrrole derivs. It was, therefore, not injected. The conclusion is drawn that oxidizability of these adrenaline-like substances is directly proportional to the no. of OH groups in the nucleus, and therefore the more the nucleus is oxidized, the more it is oxidizable. The hypothesis is advanced that tyrosinase acts on adrenaline-like substances giving red and then black derivs. only if at least one H of the amino group is free. PETER MASUCCI

Vagus function and adrenal insufficiency. GAETANO VIALE. *Arch. fisiol.* 28, 9–24(1930).—In adrenal operated dogs, the vagus function is unchanged; the hemodynamic action of adrenaline is increased and that of choline is decreased. Vagotomy lowers the pressure and the rhythm of the heart. Preventive injections of ergotamine or ergotoxine inhibit the tachycardia caused by vagotomy in normal dogs. Ergotamine, given after vagotomy, causes a decrease of the heart rhythm. Ligation of the adrenals lowers the pressure and retards the rhythm of the heart after vagotomy. Tachycardia caused by vagotomy is due to adrenalinemia. The sympathetic action on the heart is independent from adrenaline. Adrenaline probably exerts a central action on the vagus. A. E. MEYER

The action of heavy metals on the spinal cord. MICHELE MITOLO. *Arch. fisiol.* 28, 89–113(1930). Cu, Fe, Au and Sn have a paralyzing effect on the coördinate sensory centers of the posterior cornu of the spinal cord; they are inactive on the motor centers. Mg, Hg and Pb paralyze the motor centers only. Zn produces depression in both centers. Ag, as $AgNO_3$, has an exciting effect on the coördinate sensory centers but is inactive on the motor centers. A. E. MEYER

Gomether as a general anesthetic. José R. Ríos. *Semana méd.* (Buenos Aires) 1931, I, 396–7.—A mixt. of 80 cc. Et_2O and 10 cc. gomenol is recommended as an anesthetic in pulmonary lesions. A. E. MEYER

Insulin in diabetes of children. PEDRO B. LANDABURE AND FÉLIX PUCHULU. *Semana méd.* (Buenos Aires) 1931, I, 446–50.—The daily doses must be divided into 2, 3 or even 4 injections in suitable relation to the meals. A. E. MEYER

The local application of saturated solutions of magnesium sulfate. S. JOUAN. *Semana méd.* (Buenos Aires) 1931, I, 459; cf. *C. A.* 25, 1909.—The effect on tumefactions, purulent inflammations, stings of insects, etc., is due to osmotic changes. A summary of the beneficent actions is given. A. E. MEYER

Cessation of attacks of auricular paroxysmal tachacardia by the use of calcium.

JOSEPH B. WOLFFE AND SAMUEL BETTET. *Ann. Internal Med.* **4**, 795–803(1931). JOHN T. MYERS

Tribromoethanol anesthesia. RALPH W. WATERS AND G. W. MUEHLBERGER. *Arch. Surgery* **21**, 887–911(1930).—When kept at room temp., 3% solns. of tribromoethanol are stable toward hydrolysis for 24–48 hrs. It has practically the same margin of safety as other commonly used anesthetics, *i. e.*, $^2/_3$–$^3/_4$ of the fatal dose. With proper precautions, 0.1 g. per kg. body wt. can be safely given. It is useful, given intravenously, in very short operations, as it gives quick pleasant induction and recovery without gastro-intestinal disturbance. JOHN T. MYERS

The toxicity of atmospheres containing hydrocyanic acid gas. JOSEPH BARCROFT. *J. Hyg.* **31**, 1–34(1931).—The sp. power of HCN gas to increase the total ventilation is an important factor in detg. the sp. toxicity of the gas. Man is relatively insusceptible to the inhalation of HCN. The time of exposure sufficient for collapse is about one third of the fatal period of exposure. The extreme susceptibility of the canary makes it very valuable as an indicator of lethal concns. where a chem. indicator is not available. Pigeons are as good since they vomit at the lethal concn. for the canary, although their lethal concn. is about twice as great. Treatment consists of artificial respiration, and the administration of glucose and nitrites. JOHN T. MYERS

Experimental dust inhalation in guinea pigs. F. HAYNES. *J. Hyg.* **31**, 96–123 (1931).—Most inhaled particles contain sol. matter at least to a small extent. The solute may be harmlessly active or toxic. If harmless the cell is stimulated to detach itself from the alveolar wall and to remove the dust. If toxic the solute affects the viability of the phagocyte which becomes less able to detach itself. At the same time the solute diffuses into the neighboring tissues with irritation to them and subsequent fibrosis The more sol. form of a substance causes the greater damage; hence the solute has much to do with extent of damage. Si is the dust par excellence in predisposing to tuberculosis. The harmful effects of sol. Si may be neutralized by simultaneous administration of basic dusts as $Al(OH)_3$ or $MgCO_3$ although the latter are harmful when inhaled alone. It is suggested that the respective solutes combine to form monosilicates which are harmless. JOHN T. MYERS

Asbestosis bodies in the sputum: a study of specimens from fifty workers in an asbestos mill. F. W. SIMSON AND A. SUTHERLAND STRACHAN. *J. Path. Bact.* **34**, 1–4 (1931).—The inhalation of asbestos dust in high concns. leads to the appearance of asbestosis bodies in 48 out of 50 workers examd. The sputum is always mucoid in character. It may resemble egg albumin. The bodies seem to be the result of deposition on the asbestos fiber of an Fe-contg. substance elaborated by the cell. No tubercle bacilli were found in any of these cases. JOHN T. MYERS

Experimental liver necrosis from shale oil. CYRIL J. POLSON. *J. Path. Bact.* **34**, 5–12(1931).—Liver necrosis was produced in rabbits and rats by the intraperitoneal injection of shale oil. By graduating the doses it is possible to produce all stages from acute necrosis to cirrhosis. The poisonous action of the non-carcinogenic residue of shale oil is very slight. The liver was not thus affected in other animals. J. T. M.

The effect of oils on gastric secretion and motility. W. MORRELL ROBERTS. *Quart. J. Med.* **24**, 133–52(1931).—The efficiency of oils in inhibiting gastric secretion appears to bear some relationship to the degree of satn. of the constituent fatty acids, less satd. oils being more efficient The relationship between efficiency and sp. gr. and viscosity is less significant. Of related substances, only free fatty acids show inhibitory properties. Oil diminishes the response of the stomach to food or other substances but not to the effect of histamine. Oil inhibits both psychical and chem. stimulation of secretions. Its effect occurs almost entirely after it leaves the stomach. It diminishes the motility of achlorhydria. The effect on gastric motility is not secondary to its effect on secretion. It seems necessary to assume that oil after absorption exerts some restraining influence on the gastric cells and the motility, or that it leads to the formation or the liberation of some substance which acts in a similar manner. JOHN T. MYERS

Cholagog action of a few derivatives of the aliphatic series of low molecular weight. ETIENNE CHABROL, R. CHARONNAT, M. MAXIMIN AND R. WAITZ. *Compt. rend. soc. biol.* 106, 15–6(1931).—A study was made of the effects on the cholagog action caused by substituting various groups and atoms for the Cl and the CO_2H group in Cl_3CCO_2H. Conclusions: (1) The cholagog action disappears when the CO_2H group is replaced by an amide, alc. or Me group. (2) $BrCH_2CO_2H$ causes an immediate and powerful cholagog action, but its toxicity is too great for a prolonged study; glycine in a 2-gr. dose doubled the biliary flow during 1 hr. with a 17.5 kg. dog but was completely inactive in doses of 1 gr. with other dogs; glycolic, cyanoacetic, glyoxalic and malonic acids had no

effect in 1-gr. doses with dogs of about 20 kg.; hippuric acid had a very distinct action on 2 animals. (3) Of the compds. in which both groups are replaced at the same time, EtCl is completely inactive but EtBr or EtI increases the cholagog action when large doses are used; $CHCl_3$ and CCl_4 are completely inactive. ALBERT L. RAWLINS

The cholagog action of chlorine derivatives of acetic acid. ETIENNE CHABROL, R. CHARONNAT, M. MAXIMIN AND R. WAITZ. *Compt. rend. soc. biol.* **106**, 17–8(1931).—There is no close relationship between the cholagog action and the no. of Cl atoms in the Cl derivs. of AcOH. AcOH, $ClCH_2CO_2H$, Cl_2CHCO_2H and Cl_3CCO_2H were tested in molecularly equiv. doses of their Na salts; the acids represented thus amounted to 0.40, 0.60, 0.80 and 1.0 gr., resp. AcOH had no cholagog action; $ClCH_2CO_2H$ gave const. results, at least doubling and sometimes quadrupling the flow of bile and at the same time increasing the concn.; Cl_2CHCO_2H had no action; Cl_3CCO_2H doubled the biliary flow and increased the concn. of bile from 2.70 to 3.15. ALBERT L. RAWLINS

Respiratory stimulation by sodium sulfide. C. HEYMANS, JEAN J. BOUCKAERT AND L. DAUTREBANDE. *Compt. rend. soc. biol.* **106**, 52–4(1931).—Two series of expts. with dogs show that the stimulating action of Na_2S on respiration is largely reflex from the carotid sinus and is only very slightly due to a direct stimulating effect on the respiratory center. ALBERT L. RAWLINS

Carotid sinus and respiratory reactions by cyanide. C. HEYMANS, JEAN J. BOUCKAERT AND L. DAUTREBANDE. *Compt. rend. soc. biol.* **106**, 54–5(1931).—A series of expts. was performed with dogs in which the cyanide was caused to act solely on the carotid sinus and then solely on the centers. The results show that the inhibitory action of cyanide on respiration is due to the sensitiveness of the carotid sinus to cyanide, and not due to the action of the cyanide on the centers. ALBERT L. RAWLINS

The hypoglucemic action of sulfur. Sulfur mineral waters. I. DANIEL AND M. POPESCO-BUZEU. *Compt. rend. soc. biol.* **106**, 106–7(1931).—The action of sulfur water on dogs and normal and diabetic patients is contrasted with the action of distd. water. In all cases where the sulfur mineral water was used there was a pronounced diminution of blood sugar, while distd. water had no effect. The authors believe that the hypoglucemic action should be attributed to the colloidal S and H_2S in the water. ALBERT L. RAWLINS

The action of commercial glucose, comparatively administered by the digestive and intravenous methods, on the glycogen content of the liver, heart and muscles. D. SIMICI, M. POPESCU AND A. CRAIFALEANU. *Compt. rend. soc. biol.* **106**, 112–5(1931). The glycogen content of the liver, heart and muscles was detd. with 12 rabbits administered com. glucose by digestive and intravenous methods following a fast. To increase the liver glycogen the digestive method is more effective than the intravenous while to increase the glycogen content of the muscles, and particularly of the heart, the intravenous method is incomparably superior. ALBERT L. RAWLINS

Pharmacodynamic action of hydrogen sulfide introduced into the digestive tract. F. KMIETOWICZ. *Compt. rend. soc. biol.* **106**, 126–8(1931).—In a study with dogs the following behavior of H_2S was demonstrated: large doses introduced into the intestine first cause an acceleration of respiration and then cessation with death resulting; the blood pressure is raised; the heart rate is lowered, with an increase of amplitude; artificial alkalosis, acidosis and the injection of morphine increase the toxicity of H_2S, alkalosis having the greatest effect. The mechanism of the above actions is discussed. The absorption of H_2S is greater in the small intestine than in the large intestine. H_2S shows analogous but less distinct behavior when introduced by mineral water. ALBERT L. RAWLINS

Action of iodine, calcium and magnesium ions on the oscillometric index and arterial pressure in transcerebral dielectrolysis. GEORGES BOURGUIGNON AND SOCRATE ELIOPOULOS. *Compt. rend.*, **192**, 379–82(1931); *Compt. rend. soc. biol.* **106**, 454–8 (1931); cf. G. Bourguignon, *Rev. Actinologie* **5**, II, 180, March–April 1929. ALBERT L. RAWLINS

"Dial" a surgical anesthetic for neurological operations with observations on the nature of its action. J. F. FULTON, E. G. T. LIDDELL AND D. McK. RIOCH. *J. Pharmacol.* **40**, 423–32(1930).—For cats and dogs 0.5 cc. per kg. administered intraperitoneally was sufficient for surgical anesthesia. The motor cortex still reacted to electric stimulation. From this fact, and from other observations (of chop licking, salivation, vomiting, indicating an effect on the medulla, and of absence of excitement and a resemblance to natural sleep) it is suggested the site of action of Dial is in the hypothalamus and medulla. C. RIEGEL

The calorigenic action of morphine as revealed by addiction studies. H. G. BARBOUR, D. E. GREGG AND L. G. HUNTER. *J. Pharmacol.* **40**, 433–50(1930). Three

of 4 dogs after 7–10 weeks on morphine showed a basal metabolism higher than normal, and this high value dropped on withdrawal of the drug. Basal N excretion was decreased, although total N output increased. Carbohydrate combustion increased, fat combustion decreased. It is suggested that narcotic action may be due to inhibitory impulses arising peripherally from the calorigenic stimulation. C. RIEGEL

The reaction of iodates in vivo. L. C. MAXWELL. *J. Pharmacol.* **40**, 451–5 (1930).—Lethal intravenous dose of $NaIO_3$ was 100 mg. per kg. for rabbits. A dose of 75 mg. caused appearance of toxic symptoms (convulsions, spastic paralysis, irritation of mucus membranes, albuminuria). The toxicity of the iodate increased in the presence of NaI. The toxicity apparently is not due to liberation of I in the tissues. C. R.

Urinary sulfur and thiocyanate excretion in cyanide poisoning. RALPH G. SMITH AND RUSSELL L. MALCOLM. *J. Pharmacol.* **40**, 457–71(1930).—Rabbits on a const. diet were allowed to breathe HCN fumes for certain periods for a number of days. Inorg., and conjugated sulfates, neutral S and thiocyanate excretion in urine were detd. Neutral S increased during cyanide administration, the increase being accounted for by excretion of thiocyanate. Inorg. sulfate decreased in most cases, so that total S was the same, or less. An increase in total N caused an increase in N:S ratio. After intravenous injection of NaCN 61–100% of the cyanide given was recovered in the urine during the 1st three days as thiocyanate. Conclusions: Increased urinary neutral S is due to detoxication of cyanide rather than depressed oxidation processes. Thiocyanate formation is the principal method of cyanide detoxication. C. R.

Hemoglobin production. II. The relief of anemia, due to milk diet, by feeding amino acids. DAVID L. DRABKIN AND H. K. MILLER. *J. Biol. Chem.* **90**, 531–43 (1931).—The effect of the addn. of amino acids relatively free from Fe to anemic rats on a whole-milk diet contg. 0.2 mg. Fe per day was studied. All the prepns. were free from Cu and from other heavy metals. Alanine, alanine-HCl, histidine-2HCl and HCl alone had no effect on hemoglobin production, indicating that in this type of anemia the relief of achlorhydria is not essential (cf. McLester, *J. Am. Med. Assoc.* **95**, 719 (1930)). Arginine and Na glutamate rapidly produce continuous hemoglobin regeneration. Tryptophan, Na aspartate, pyrrolidonecarboxylic acid and a proline mixt. from hydrolyzed gelatin produce a temporary increase in hemoglobin production. It is suggested that the effective substances act as a source for the synthesis of pyrrole rings for the heme mol.; the absence of either Fe or of these substances produces anemia. K. V. THIMANN

A study of electrolyte equilibrium in the blood in experimental acidosis. HENRY N. HARKINS AND A. BAIRD HASTINGS. *J. Biol. Chem.* **90**, 565–95(1931).—The effect of injecting 2–3 cc. *N* HCl per kg. body wt. into dogs was followed by CO_2, p_H, ion distribution and refractive index measurements. The acid caused an anuria so that very little of the excess Cl was excreted. The p_H fell to 6.9 and in 2 cases to 6.1. Hyperpnea began 20 sec. after the start of the injection, but respiration became normal again in 1 min., while the p_H had not returned to normal in 3 hrs. or more. The respiratory center was not inactive, as shown by response to minimal elec. stimulus, and hence the p_H is not a respiratory hormone. The distribution of HCO_3 and Cl ions between cells and plasma was according to the Donnan relation throughout (Van Slyke, Wu and McLean, *C. A.* **17**, 3046), even on the acid side of the isoelectric point of hemoglobin. The refractive index of the serum was increased, and the water content decreased. The water content of the cells, however, and the Cl contents of both cells and serum were increased. Two expts. on blood *in vitro* gave essentially similar results. K. V. T.

The comparative effect of strychnine in the normal and dehepatized frog. J. T. PRIESTLEY. *Proc. Staff Meetings Mayo Clin.* **6**, 71(1931).—Liverless frogs showed a reaction to a given dose of strychnine that was more than twice as severe as that given by normal or splenectomized frogs. Partially dehepatized frogs were distinctly more susceptible to strychnine than normal or splenectomized frogs. R. C. WILLSON

β-Phenylethylamines. I. Mescaline and mescaline-like substances (SLOTTA, HELLER) **10. Some synthetic bases similar to ephedrine** (CHERBULIEZ, *et al.*) **10.**

JOHANNESSOHN, FRITZ: **Kinine in de geneeskundige Practijk aan de Hand van de Gegevens der Pharmacologie.** Amsterdam: Bureau tot Bevordering van het Kinine-Gebruik. 210 pp.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

An outbreak of food poisoning in Staffordshire. I. The clinical manifestations. E. S. CLAYTON AND V. E. MILNE. *Brit. Med. J.* **1930, II, 684–5. II. Bacteriological investigation.** JOHN MENTON. *Ibid* 685–6.—A report is given of a limited outbreak of food poisoning due to eating pie made from pork infected with hog cholera bacillus.
J. B. BROWN

Use of buffers in determination of color by means of titanium trichloride. II. O. L. EVENSON AND R. H. NAGEL. *Ind. Eng. Chem., Anal. Ed.* **3**, 167–9(1931); cf. *C. A.* **22**, 3780.—Analysis of food colors by titration with $TiCl_3$ is made fairly accurate by the addn. of properly chosen buffer catalysts such as Na citrate or bitartrate.
H. F. LEUPOLD

The viscosities of alkali solutions of pure wheat flours and their relation to practical baking research. THEODOR BIÉCHY WITH ROBERT MÜLLER, GRAMS AND NÜCHTER. *Kolloid-Z.* **54**, 194–210(1931).—The viscosities of 0.05 *N* NaOH solns. of wheat flours are const. after 2 hrs. and were detd. at 20° with a Lawaczeck falling-body viscometer. A standard comparison may be made by comparing the viscosity of a soln. in 0.05 *N* NaOH contg. enough flour to contain 1 g. of gluten per 100 cc. The gas-holding capacity of dough was detd. at 32° with the Tillmann app. The following relation was found to hold for the wheat flours tested: [Teiggärkraft × standard viscosity]/Bread vol. (100 g. flour) = const., where Teiggärkraft is the difference between original and final dough vol.
ARTHUR FLEISCHER

Bakers' yeast. I. Influence of age upon the fermentation time of the yeast. E. ROSENBAUM. *Z. Untersuch. Lebensm.* **59**, 607–12(1930).—The manuf. of yeast cake from beet-sugar molasses is described. Analytical data on 20 samples of yeast are given. The moisture contents as detd. by heating 4 hrs. at 105–8° were 72–3%. High moisture content is assocd. with poor keeping quality. Keeping quality was detd by the time required for the cake to soften when heated at 35°, the times varied from 55 to 105 hrs. The N contents varied from 1.81 to 2.52% of the dry substance, corresponding to protein contents of 41.38–57.25%. The fermentation time is the time taken by a dough of standard compn. pressed into a mold of fixed dimensions to rise 5 times in succession to a height of 7 cm. above the mold. The sum of the 5 periods, or total fermentation time, showed great variation, 176–271 min. The fermentative power of the yeast decreases rapidly on storage, but deterioration is reduced by storage at low temps.
C. R. FELLERS

Development and heat economy of the gas bakery oven. W. RAISS. *Arch Wärmewirt.* **11**, 381–6(1930).—The development of the various German types of gas ovens for baking bread is discussed. A successful gas oven will not imitate the models for solid fuels, but must have a min. of wt. and good insulation.
E. W. T.

Milk considered as a complete and biologically balanced food. RAOUL LECOQ *Bull. soc. hyg. aliment.* **18**, 481–509(1930).—A review.
A PAPINEAU-COUTURE

The pigments of milk. MARTIN LUNDBORG. *Biochem. Z.* **231**, 274–89(1931) The natural yellow color of butter fat is due to carotene, as can be ascertained by the carotene spectrum of the unchanged fat. The tintometric detn. of the carotene according to Lovibond is unreliable because of the very min. quantities present. More reliable results are obtained from studies on the sapon. residue. Five cc. of a freshly prepd. 20% alc. KOH is used for the sapon. per g. fat, and the sapon. is carried out for 45 min. over a boiling water bath in an Erlenmeyer flask provided with a long reflux tube. The reaction mixt. is dild. with 10 vols. of H_2O, and this is then extd. 4 times with $^1/_4$ its vol. of ether. The combined ether exts. are dried 2 hrs. with anhyd. Na_2SO_4 and evapd. at 50–55°, the last stages *in vacuo*. The residue is transferred quantitatively to small measuring cylinders with small quantities of anhyd. chloroform, and the tintometric detns. are made on these solns. For this purpose the chloroform soln. is layered over $SbCl_3$ soln., and the contents are carefully mixed and examd. in the tintometer. Direct extn. of the milk fat is impossible; the extn. of the fat with petr. ether from milk acidified with lactic or acetic acid is also full of difficulties, since the acid destroys the carotene when the petr. ether is evapd.
S. MORGULIS

Determination of milk fat. A. C. ANDERSON. *Z. Untersuch. Lebensm.* **59**, 600–2 (1930).—In the detn. of fat in milk which is in an incipient state of decompn., sepn. of the fat as in the Roese-Gottlieb method may lead to low results because of sapon., even if $K_2Cr_2O_7$ has been added as a preservative. It is preferable to use the Schmid Bondzynski-Ratzlaff method as follows: Ten g. of milk is mixed with 10 cc. of HCl,

d. 1.19, and boiled for 4–5 min.; heat is applied as gently as possible to avoid discoloration. After cooling, the mixt. is extd. with 10 cc. of alc., 25 cc. of Et_2O and 25 cc. of light petroleum as in the Roese-Gottlieb method. C. R. FELLERS

Determination of the milk proteins. III. Proposed modified method for casein. GEORGE M. MOIR. *Analyst* **56**, 147–9(1931); cf. *C. A.* **25**, 1597.—The following modified method is proposed for the detn. of casein: Dil. 10 ml. of milk with 50 ml. of water which has been heated to 40–42°. Add at once 1.5 ml. of 1.67 *N* AcOH and stir by rotating the contents of the beaker 4 times against a stirring rod. After 20 min. add 4.5 ml. of 0.25 *N* NaOAc soln. and filter after it has stood an hr. or more. Wash promptly and det. the N content of the casein by the Kjeldahl method with Na alizarine sulfonate as indicator in the final titration. The directions are given in detail together with several important explanatory notes. W. T. H.

The determination of the calcium, magnesium and acid-soluble phosphorus of milk by means of trichloroacetic acid filtrates. GEORGE P. SANDERS. *J. Biol. Chem.* **90**, 747–56(1931).—The proteins of milk can be completely ppted. by [illegible] can be used for the detn. of Ca and Mg with a high degree of accuracy, and 1 working day is saved in the prepn. of samples. The procedure should also be of value in studying P combinations in milk with particular reference to casein and lipide P. In several milk samples 68.4 to 81.9% of the P was found to be acid-sol. There was no definite correlation between the amt. of acid-insol. P and the casein content, but in general milk high in casein was high in acid-insol. P. A. P. LOTHROP

Determination of the volatile fatty acids in the milks of the cow, goat and sheep. VITTORIO BORRA. *Pediatria rivista* **39**, 102–9(1931).—In the course of his investigations on the origin of the anemia resulting from the use of goat milk, B. made comparative analyses on the quantity of volatile fatty acids present in the milks of cows, sheep and goats. The Reichert-Meissl no. for the milks of the goat, cow and sheep was 7.72, 3.58 and 2.55, resp., while the Polenske no. was 3.76, 1.49 and 0.87, resp. G. S.

Simple calculation of the limit of value of the microscopical examination of milk for tubercle bacilli. D. R. WOOD. *Analyst* **56**, 179–80(1931); cf. *C. A.* **24**, 5387.—Without concn. (and the concn. methods are not really successful) from 10 to 500 bacilli per cc. can be detected by microscopical examn. If cases are excluded in which there is a bulky deposit, characteristic of tubercular mastitis complicated by streptococcal mastitis, and if the attention is confined to milk giving a normal deposit of not more than 2.5 cc. in a vol. of 100 cc., the microscopic detection is limited to the detection of not less than 10–50 bacilli per cc. and is, therefore, less than 1/500 as sensitive as the biological method. W. T. H.

Crystallization of lactose in sweetened condensed milk. B. SEGAL. *J. S. African Chem. Inst.* **13**, 33–40(1930). The texture of sweetened condensed milk is a function of the size of the lactose crystals. In the cooling of condensed milk during manuf. the immediate production of a large no. of crystal nuclei, rather than the growth of crystals around a small no. of centers, should be the aim. B. C. A.

Studies on the use of dry skim milk in manufacturing ice cream. C. D. DAHLE AND J. I. KEITH. *Ice Cream Trade J.* **27**, No. 1, 33–5(1931).—When dry skim milk of good quality was used in place of condensed skim milk in ice cream mixes contg. cream and milk, the resulting ice cream scored as high as the condensed skim milk controls. When dry skim milk was used in conjunction with butter, the score of the ice cream was lower than when cream was used. Mixes contg. butter and skim-milk powder yielded the desired overrun more slowly than mixes contg. cream and powder. From the standpoint of flavor, texture and body dry skim milk of good quality can be successfully used as a substitute for condensed skim milk in mixes contg. cream and fluid milk as a source of fat One half lb. of dry skim milk can be successfully used in one gallon ice cream mix under the conditions mentioned. A. H. JOHNSON

The causes and prevention of cream feathering. F. J. DOAN. *Creamery and Milk Plant Monthly* **20**, No. 1, 33–8(1931).—Fresh unhomogenized table cream rarely exhibits feathering in coffee. Creams which have become acid on account of fermentation and homogenized creams are susceptible to feathering. The feathering of homogenized creams was shown to be due to fat clumping. Homogenization of cream in such a way as to prevent fat clumping reduced the tendency to feather. Cream for prepg. homogenized table cream should be fresh, of low acidity, and should be pasteurized at 160–62°F. for 30 min. or, if a flash method is used, at a temp. of 175°F. The cream should then be homogenized at the same temp. If single-stage homogenization is used, the cream should be rerun at once while hot at about 1000 lb. pressure. When a two-stage machine is used, the pressure on the second valve should not be in

excess of the pressure on the first. If feathering cannot be prevented by these procedures, certain salts such as Na citrate, $NaHCO_3$ and Na_2HPO_4 may be added. The amt. of these salts to be used varies, but 0.025 to 0.10% will usually be sufficient. The salt should be added prior to homogenization. A. H. JOHNSON

The hygienic supervision of butter. A. D'AMBROSIO. *Ind. olii minerali e grassi* **10**, 169–71(1930); cf. *C. A.* **24**, 5888.—On 114 samples of butter taken between December and April when the cows were fed with dry hay, only 8 had the value of the sol. volatile acids under 26. Feed, such as grass, richer in volatile acids, produced butter richer in these. The stage of lactation has an effect on the production of rich milks. After the period of the colostrum, the quantity of the volatile fatty acids decreases from a very high figure to normal. Other conditions, such as estrus, weaning of the calf, etc., affect the compn. of the milk. Many controlled samples of butter gave the const. limits: Zeiss refractometer reading at 35° 43.2–49.5, sol. volatile acids no. 20.8–35.15, insol. volatile acids no. 1.1–3.0. R. SANSONE

New methods of analysis of oils and fats, with particular reference to butter analysis. S. FACHINI AND G. DORTA. *Atti III congresso naz. chim. pura applicata* **1930**, 683–7. Three and a half g. of butter is melted and filtered; then the sapon. no., sol. fatty acids, fixed fatty acids, I no., mol. wt. and *n* of fixed fatty acids are detd., and the fixed fatty acids are sepd. into a group contg. caprylic, capric and oleic (linoleic) acids not pptd. from soln. in acetone by KOH and a group contg. lauric, myristic, palmitic and stearic acids pptd. from soln. in acetone by KOH. The I no., mol. wt. and *n* of the first group are calcd. From the I no. the content of caprylic and capric acids and the av. mol. wt. of these 2 acids in the mixt. can be calcd. The *n* of the first group, for all grades of butter tested, was 1.4510–1.4500 at 25°; palm oil gives 1.4391–1.4380. E. M. S.

Analysis and composition of vegetable parchment used for packing dairy products. PAUL ARUP. *Analyst* **56**, 149–61(1931).—The following detns. were carried out on 10 com. samples of parchment paper; water, ash, water-sol. ext., reducing material such as dextrose, bursting strength (wet and dry), wt. per ream and power to support mold growth. The methods used are described and the results tabulated. As a result of these detns. the conclusions drawn are: The moisture content should not exceed 10%. The bursting strength, as detd. by the Ashcroft tester, should be at least 25 lb. per sq. in. for parchments weighing 25 lb. per ream and 18 lb. per sq. in. for material weighing 18 lb. per ream. The strength immediately after being wetted should be at least 33% of the strength of the unwetted material. The ash should not exceed 0.45% and the water-sol. ext. 1.30%. The percentages of reducers in the water sol. ext. were calcd. as a guide for the detection of added sugar. Certain standards adopted by Germany (8% of ext. and 3% of ash) are considered too high, being due probably to the addn. of sugar and salt. An unduly high content of ext. renders the paper particularly susceptible to attack by mold. The water-sol. ext. from genuine parchment consists of the decompn. products of lignocellulose and can be characterized by method of Cross and Bevan. W. T. H.

Fatty acids and component glycerides of Indian ghee. R. BHATTACHARYA AND T. P. HILDITCH. *Analyst* **56**, 161–70(1931).—Ghee is clarified butter or cream used in India in place of butter which, because of climatic conditions, is not suited to Indian methods of cooking. To prep. ghee, the thick scum that forms on boiled milk which it is allowed to stand in a warm place is skimmed off, mashed and churned with added cold water toward the end. The resulting buttermilk is removed, and the residual fat is heated gently in an open pan, strained and stored. Two samples of cow ghee and 2 of buffalo ghee were analyzed, one sample from a stall-fed animal and the other from a pastured one in each case. The butter fat content of the cow ghee was similar to that of ordinary butter. The Reichert-Meissl values and the % of butyric acid were toward the lower values obtained by Hilditch and Sleightholme in butter from New Zealand cows, but the oleic acid content was normal. The stearic acid content is higher in the fat from the stall fed cow than from the pastured animal, and the palmitic acid value is normal for butter fat or beef tallow. The corresponding specimens of buffalo ghee were not very different, although there is distinctly more butyric acid which corresponds to somewhat higher Reichert-Meissl and Kirschner values. The most apparent difference lies in the increased content of stearic acid and the presence of arachidic acid. Broadly speaking, it would appear that the main characteristics of the fatty acids in a fat are fairly well defined for a given species of animal, subject to minor variations due to varying climatic and feeding [illegible] With respect to the glyceride structure of the ghee, it is of the mixed "heterogeneous" type. There is no evidence of segregation of any fatty acid into a simple triglyceride, and all the satd. fatty acids are found, in more or less the same ratio, in each part of the fat. It

is doubtful whether triolein is present in appreciable amt., and the tripalmitin or tristearin present must be small if any. The 4 fats studied were of first quality, comparable in flavor and odor to the best butter fats. W. T. H.

The botany and chemistry of the soy bean. W. Riede and B. Rewald. *Landw. Vers. Sta.* **110**, 291–304(1930).—Seven samples of soy bean raised in Germany analyzed N 5.97–6.02, protein 36.59–41.37, fat 14.67–17.39 and phosphatides 1.02–2.53%. These figures are reduced to a basis of 12% H_2O. John R. Hill

Determination of moisture in soy beans. L. Jolson. *Mém. Univ. État Extrême-Orient* **13**, No. 6, 1–23(1929); *Chimie & industrie* **25**, 145(1931).—From a study of drying at 100–5° and at 120–60°, of distn. in presence of xylene, and of the effects of the fineness of grinding, wt. of samples and temp. and time of drying, J. concludes that all 3 methods give satisfactory results provided the conditions are properly selected and strictly adhered to. He recommends grinding to pass a 1.5–2.5-mm. mesh sieve and drying 5 g. for 20 min. at 130°. Drying at 100–5° requires 5–8 hrs. and should not be continued to const. wt. A. Papineau-Couture

Mineral, nitrogen and fat content of some varieties of mature bean seed and of string beans. J. S. McHargue and W. R. Roy. *J. Nutrition* **3**, 479–81(1931).—Twelve samples were analyzed for protein, fat, etc., as well as for mineral content. Both string beans and ripe beans are very rich in mineral constituents and S. It is probable that the curative property of beans for beri beri is assocd. with their relatively high mineral content. C. R. Fellers

Carbohydrates of the lotus rhizome. Teizo Takahashi and Hatsunao Yokoyama. *J. Agr. Chem. Soc. Japan* **6**, 870–2(1930).—The lotus rhizome is a common food in Japan. Most of the sugar fraction was non reducing sugar. From the hot alc. ext. of the rhizome powder sucrose was isolated. Raffinose, galactose and galactane could not be detected. The polysaccharides were mostly starch and cellulose. Y. K

Vitamin B content of raw and canned beef. Yoshio Umishio. Imp. Zootech. Expt. Sta (Japan), *Bull.* **25**, 12 pp.(1930).—For normal growth of rats, the min. daily requirement of vitamin B is supplied by an alc. ext. of 20 g. raw or 40 g. canned beef. The vitamin B content of canned beef is not diminished during storage for 4–5 years. K. Kitsuta

Detection of the onset of decomposition in meat by the content of ammonia in the form of salts. F. M. Litterscheid. *Z. Untersuch. Lebensm.* **59**, 599–600(1930).—The effect of NH_3 gas from a leaky NH_3 system for cold storage on the appearance and quality of meat is described. NH_3 contamination may be detected by testing the rinsing water with Nessler's soln. In conducting the Glassmann-Rochwarger test (*C. A.* **24**, 3063) for incipient putrefaction and for the detection of NH_3 in flesh, L. recommends that the outer and inner portions of the meat be examd. separately to det. whether the meat has been exposed to NH_3 gas or has been dressed with NH_4 salts as preservatives. C. R. Fellers

Citrus fruit production in the Lower Rio Grande Valley of Texas. Hamilton P. Traub and W. H. Friend. Texas Agr. Expt. Sta., *Bull.* **419**, 60 pp.(1930).—Very complete pomological, phys. and chem. data for grapefruit, oranges, lemons, kumquats, tangerines, etc., are given. For grapefruit, total sol. solids range from 8.3 to 10.5%, total sugars from 5.8 to 7.0, total acidity as citric from 0.96 to 1.4, p_H from 3.1 to 3.3, protein from 0.42 to 0.53 and ash from 0.19 to 3.0. C. R Fellers

Acid to sugar ratio in oranges. D. J. R van Wijk. *J. S. African Chem. Inst.* **13**, 52–8(1930).—Examn. of 3 typical varieties of oranges shows that maturity as commonly judged from the ratio, acid degrees Brix of the juice, is unsatisfactory. A better basis of comparison is the ratio acid: "calcd. sugar" (where calcd. sugar = degrees Brix − acid − 1.75). The value 1.75 represents the contribution of extraneous matter, other than acid and sugar, to the d. of the juice and is fairly const. for all samples examd. B. C. A.

Banana—a challenge to chemical investigation. H. von Loesecke. *J. Chem. Education* **7**, 1537–43(1930).—Bananas soften on ripening because of the change of protopectin into pectin. When overripe the pectin has changed to acids. Ethylene has little effect on ripening bananas except on "dormant fruit." Banana vinegar compares favorably with cider vinegar. Ripe banana flour has some therapeutic value. Bananas are rich in vitamin A and C and also contain B, G and E. Ann Nicholson Hird

Effect of solid carbon dioxide upon transportation diseases. Charles Brooks. *Phytopathology* **21**, 103(1931).—It is possible by the use of solid CO_2 to secure a CO_2 content of the atm. of a car within 30–60 min. which will check rotting and softening of warm fruit as much as would a 30–40° drop in temp. It is essential that the gas escape within the next 18–24 hrs. or injury to flavor may result, especially with peaches,

red raspberries and strawberries. Dewberries, blackberries, cherries and plums are more resistant to injury. Grapes, sweet corn, peas and beans offer the greatest promise of beneficial effects without harm to the product. JOSEPH S. CALDWELL

Photoactivity of honey. J. STITZ. *Z. Untersuch. Lebensm.* **59**, 606–7(1931); cf. *C. A.* **23**, 2223.—The possibility of Ra in the ash of honey was investigated by placing the ash as well as natural honey in both glass and quartz containers and subjecting them for 30 days to contact with photographic plates. Other samples were irradiated with ultra-violet light and Röntgen rays and similarly exposed. All results were neg. for Ra. C. R. FELLERS

A rapid method for the determination of crude fiber. U. H. PURANEN AND E. S. TOMULA. *Acta Chem. Fennica* **3**, 85–9(1930).—The Weede method consisted in treating 3 g. of the crude fiber with ether to remove fats, boiling for $^1/_2$ hour with 200 cc. of 1.25% H_2SO_4, filtering and washing until wash water was neutral. The residue was boiled for $^1/_2$ hour with 1.25% KOH, washed, dried and ignited. The process took several days due to the colloidal nature of the soln obtained and the difficulty in filtration. If the vol. fell below 172–181 cc. on boiling, the analysis showed 23.64% crude fiber (theoretical 26.08%), while if the vol. was 223–227 cc., the result was 26.53%. A later method involved the direct neutralization of the acid with KOH so that a large excess of KOH was present during the second boiling. The results were always high. The proposed method was to reflux 3 g. of finely ground fiber with 50 cc. of 5% H_2SO_4 and 150 cc. of H_2O for $^1/_2$ hr. The flask was allowed to cool somewhat and 20 cc. of 28% KOH was added with a pipet. After refluxing $^1/_2$ hr., cooling, filtering on asbestos, washing with hot H_2O, with 1.25% acid, again with hot H_2O, and finally with alc. and ether or acetone, the residue was dried at 105° and ignited. S. A. KARJALA

New procedure in the chemical investigation of fodder and foodstuffs. J. KÖNIG, F. BARTSCHAT AND B. STEMPEL. *Z. Untersuch. Lebensm.* **59**, 564–72(1930).—The deficiencies in the normal methods of recording the constituents of foodstuffs are enumerated, and a systematic scheme is presented for analysis and sepn. into the following groups: water content; fat (Et_2O ext.); crude protein (amide + pure protein, both H_2O-sol., and sol. or insol. in 2% HCl); water-sol. carbohydrates (acid as lactic acid + sugar-reducing powers before and after inversion + dextrin + residue); starch; protocellulose and hemicellulose (including hemipentosans); *o*-cellulose and *o*-lignin including *o*-pentosans; insol. lignin, cutin and suberin; mineral matter (H_2O-sol., and sol. or insol. in 2% HCl). The results of analyses of wheat, flour and bran are tabulated as examples. C. R. FELLERS

A new method for the "sand determination" in the presence of silicic acid in feed stuffs. W. LEPPER. *Landw. Vers. Sta.* **110**, 305–11(1930).—Five g. of the substance is ashed over a small flame. Twenty cc. NaOH (15%) is added to the ash in a Pt or porcelain dish which is covered with a watch glass and heated on a water bath for $^1/_2$ hour It is then washed into a beaker, dild. to 400 cc., and 100 cc. HCl (1:1) is added to it. The mixt. is stirred and filtered and the ashed residue is the "sand." JOHN R. HILL

Report on the work of the laboratories of the Central Experiment Station on feeding. I. Bioenergetics laboratory. J. LEFÈVRE AND A. AUGUET. *Bull. soc. hyg. aliment.* **18**, 328–39(1930). **II. Biological chemistry laboratory.** M. JAVILLIER. *Ibid* 339–43. **III. Physiological laboratory.** L. RANDOIN. *Ibid* 369–89. **IV. Laboratory and experiment station for investigations on livestock feeding.** J. ALQUIER. *Ibid* 390–435.—A review of the investigations carried out to date in the various labs., the results of which have already been reported to the Fr. Dept. of Agr. A. P.-C.

Fodder and quality of milk in meadow fertilization with calcium cyanamide. L. HERMANN. *Milchwirtschaft. Forsch.* **9**, 142–60(1929).—In a study on feeding fodder from land fertilized by Ca cyanamide the changes in acidity, density and fat content were observed. GEORGE R. GREENBANK

Determination of nitrite and sulfite in the presence of one another in meat products (SZABÓ) **7**. Vitamins and palm oil in margarine (EPSTEIN) **27**. Determination of Ca, Mg and P in feedstuffs (MORRIS, *et al.*) **7**. Determination of cholesterol and lecithin. Evaluation of egg products (TILLMANS, *et al.*) **11B**. Treatment of canning wastes (ANON.) **14**. Organic peroxide for oxidizing or decoloring (of cereals, cereal products, etc.) (U. S. pat. 1,793,917) **27**. Waterproof fibrous products for making milk bottles, etc. (U. S. pat. 1,793,839) **23**. Apparatus and procedure for spray desiccation of milk (U. S. pat. 1,794,978) **1**. Obtaining protein material from seeds (U. S. pat. 1,794,105) **27**.

Fumigating flour mills with nicotine vapors. BRABENDER ELEKTROMASCHINEN

GES. Brit. 337,311, March 1, 1929. A web of paper impregnated with nicotine is heated (as by passing it between elec. heaters which are at a temp. of 300–350°) without causing ignition but with carbonizing of the paper. App. is described.

Bread. STANDARD BRANDS, INC. Brit. 337,930, Oct. 11, 1929. A small quantity of urea (suitably with conjoint use of urease if desired, which enables a lesser proportion of urea to be employed) is mixed with the flour, yeast and other ingredients, and corn sugar, pure maltose and other sugars can be used in doughs contg. urea, with production of a satisfactory crust color. A small quantity of a slightly sol. acid substance such as mucic acid (with or without an admixture of acid Ca phosphate) may be added to counteract the effect of liberated NH_3 on the p_H of the mixt. The urea, urease and mucic acid may be preliminarily distributed in a filler such as flour, sugar or corn starch or soy-bean meal (which when used as a filler supplies urease).

Diastase baking powder. CARL H. MEYER. Swiss 141,861, Feb. 4, 1929. Malt flour is mixed with powd. dextrose, preferably maize dextrose.

Milk sterilizer. BERGEDORFER EISENWERK A.-G. ASTRA-WERKE. Ger. 517,217, July 11, 1929.

Apparatus for sterilizing milk and similar treatments. BERGEDORFER EISENWERK A.-G. Brit. 338,422, Jan. 9, 1929. Structural features.

Apparatus for pasteurizing milk, etc. ISAAC E. COLVIN, GRANT N. MANISON and HUGO G. WALTERS (to Pfaudler Co.). U. S. 1,794,670, March 3. Structural features.

Apparatus for pasteurizing milk. CORNELIUS MORTENSEN. U. S. 1,793,631, Feb. 24 Structural features of an app. with jacketed tubes.

Apparatus for drying milk, etc. HANS LÜBER. Ger. 514,785, Jan. 11, 1928. App. with roller driers for milk and colloidal liquids is described.

Thin brittle shell material for encasing ice cream, etc. WILLIS D. THOMPSON (one-third to Carl H. Crawford). U. S. 1,794,741, March 3. A compn., which is brittle when chilled to below 22°, is formed of a suitably selected asphalt mixed with over 3 times as much paraffin and with a small proportion of stearin.

Butter. E. G. N. SALENIUS and E. S. SALENIUS. Brit. 337,778, May 7, 1929. Whole milk or cream, during its passage from a centrifugal drum, is subjected to a vacuum of different degrees in different parts of the app. (various details of which are described). Cf. *C. A.* **25**, 546.

Purifying butter, margarine and other fatty materials. R. BENDLIN and O. URBASCH. Brit. 338,053, Jan. 9, 1929. Cleansing and working is effected by extrusion of the material into vermicelli-like threads which are immediately broken up by a jet of water, and the material is then passed to a settling vat and afterward is centrifuged. The washing may be repeated and alk. or acid solns. used if necessary. The procedure may be applied to removal of excess of salt which has been added to butter as a preservative. App. and various details of procedure are described.

Preserving meat by brine injections. G. BEISSER. Brit. 338,011, July 29, 1929. Various details of app. and procedure are described relating to injection of brines such as those contg. NaCl, sugar and water in specified proportions into the vascular tracts of meat carcasses such as those of pigs.

Meat-curing composition. ERNEST H. WRIGHT. U. S. 1,792,561, Feb. 17. A meat-curing material is obtained by distg. hard wood at a temp. of about 28–70° and discharging to the atm. the gases released at these temps., and then gradually increasing the temp. to about 480° and condensing the vapors evolved at these higher temps. App. is described. Cf. *C. A.* **24**, 2513.

Apparatus for sterilizing fruit juices. BERNHARD HUG. Swiss 143,205, Nov. 18, 1929. Addn. to 133,461 (*C. A.* **24**, 443). The juices are heated by immersed electrodes.

Treatment of fruits and vegetables. F. KIDD and C. WEST. Brit. 337,422, July 31, 1929. For storage, transport or ripening, fruits or vegetables are placed in chambers of metal, glass or other materials provided with apertures covered with permeable material such as rubberized fabric of such character as to control the diffusion and dependent concn. of gases such as O, CO_2 and C_2H_4 in contact with the fruits or vegetables.

Preparing fresh fruit such as citrus fruits for market. ERNEST M. BROGDEN and MILES L. TROWBRIDGE (to Brogdex Co.). U. S. 1,795,275, March 3. For prevention of blue-mold decay, the fresh fruit is treated with a warm aq. mold-inhibiting soln. of an alk. hydroxide (such as a 2% NaOH soln.) having a degree of alkalinity at least as high as that equiv. to 2 oz. of Na_2CO_3 per gal., and sufficient amt. of the soln. is allowed to dry on the fruit to exert a decay-preventing action. Cf. *C. A.* **24**, 174.

Cellulosic coatings on articles such as fruits and vegetables. GEORGE W. BEADLE (to Cellacote Co.). U. S. 1,794,751, March 3. A liquid hydrated cellulose prepn. such as cellulose xanthate soln. is applied successively to different portions of the arti-

cle completely to cover it, and the article is then treated successively with a soln. of a neutral salt such as $(NH_4)_2SO_4$ and an acid soln. such as H_2SO_4 soln. and is washed and dried. App. is described. Cf. *C. A.* 24, 2292.

Preventing blue mold of fruits such as citrus fruits. ERNEST M. BROGDEN and MILES L. TROWBRIDGE (to Brogdex Co.). U. S. 1,794,346, Feb. 24. In prepg. fruit for the market, it is treated with a warm aq. mold-inhibiting soln. such as Na_2CO_3 of a degree of alkalinity at least as high as that of a soln. of Na_2CO_3 2 oz. per gal. of water. Cf. *C. A.* 24, 901.

Apparatus (with a plurality of superposed conduits) for roasting coffee, cereals, etc. WM. L. PHILLIPS and JAMES R. NEAL (to Maxwell House Products Co.). U. S. 1,793,009, Feb. 17. Structural features.

Purine bases from cacao, etc. C. F. BOEHRINGER & SOEHNE. Brit. 338,057, Jan. 7, 1930. Natural materials such as cacao are extd. with liquid SO_2 (suitably in a rotatable pressure vessel at a temp. of about 45°), and by filtering and cooling an ext as thus prepd., a soln. of theobromine and caffeine and a layer of sepd. fat are obtained. The extn. may be repeated several times (preferably at higher temp., such as 100–105°) Tea dust may be similarly extd. for obtaining caffeine and theophylline, and mention is also made of the extn. of ground cacao shells. The material may be preliminarily treated with an alk. soln. Cf. *C. A.* 25, 775.

Irradiating chocolate with ultra-violet. ERNST OPPENHEIN. Swiss 141,862, April 9, 1929.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Technology and industrial research. O. MANFRED. *Caoutchouc & gutta-percha* **28**, 15375–6(1931).—A general discussion is given of the importance of research as evidenced by various cases which are cited. C. C. DAVIS

Our foreign trade in chemicals in 1930. OTTO WILSON. *Ind. Eng. Chem.* 23, 430–4(1931). G. G.

American Society for Testing Materials, Standards. 1930, two parts, 2214 pp. *Standard specifications* are given for: open-hearth C-steel rails; manuf. of open-hearth steel girder rails; splice bars of various types of C steel; track bolts and spikes of various kinds of steel; steel screw spikes and tie plates; structural steel of various types and uses; rivet steel for boilers and for ships; boiler and firebox steel, steel plates of structural and of flange quality for forge welding; billet-steel and rail steel concrete reënforcement bars; cold-drawn steel wire for concrete reënforcement; com. hot-rolled bar steels; com. cold-finished bar steels and shafting; C-steel bars for railway springs with and without special Si requirements; C-steel bars for vehicle and general-purpose springs; silico-Mn-steel and chrome-V-steel bars for railway springs; helical springs and elliptical springs for railways; C-steel and alloy-steel forgings and blooms, billets and slabs for forgings; quenched-and-tempered C-steel and alloy-steel forgings for locomotives and cars; C-steel car and tender axles; cold-rolled steel axles; wrought solid C-steel wheels for railways; steel tires and castings; C-steel castings for railroads; lap-welded and seamless steel and lap-welded Fe boiler tubes; welded and seamless steel pipe; C, high-speed, and alloy tool steel; C-steel castings for valves, flanges and fittings for high-temp. service; alloy-steel bolting material for high temp. service; forged or rolled steel pipe flanges and lap-welded and seamless steel pipe for high-temp. service; Zn coatings on structural steel shapes, plates and bars and their products; Zn-coated (galvanized) sheets, telephone and telegraph line wire, tie wires, fencing, barb wire and steel wire strand; welded wrought-Fe pipe; staybolt, engine bolt and extra-refined wrought-Fe bars; hollow-rolled staybolt Fe; common Fe bars, wrought-Fe plates; wrought-Fe rolled or forged blooms and forgings for locomotives and cars; Fe and steel chain; foundry pig Fe; cast-Fe pipe and special castings, soil pipe and fittings, locomotive cylinders, and wheels; malleable castings; gray-Fe castings; the arbitration test bar and tension test specimen for cast-Fe; W powder; spiegeleisen; ferro-Mn; ferro-Si; ferro-Cr; ferro-V; wire bars, cakes, slabs, billets, ingots and ingot bars of lake Cu and of electrolytic Cu; slab Zn; rolled Zn; pig Pb; Ni; Al for use in the manuf. of Fe and steel; Al ingots for remelting; Al sheet; phosphor Sn, phosphor Cu; silicon Cu; hot-rolled Cu rods for wire drawing; Cu wire of various kinds; bare Cu cable; bronze trolley wire; an alloy of Cu 88, Sn 10 and Zn 2%; sand castings of an alloy of Cu 88, Sn 8 and Zn 4%; bronze bearing metal; bronze castings, compn. brass or ounce-metal sand castings; yellow brass sand castings; Mn-bronze

sand castings and ingots for sand castings; Al-bronze castings; solder metal; Ag and brazing solders; white metal bearing alloys (Babbitt metal); lined car and tender journal bearings; Cu plates for locomotive fireboxes; Cu bars for locomotive stay-bolts; seamless boiler tubes of Cu and of brass; seamless admiralty condenser tubes and ferrule stock; seamless condenser tubes and ferrule stock of 70–30 brass and of Muntz metal; Muntz metal condenser-tube plates; Cu pipe and seamless tubes; brass pipe and forging rods; free-cutting brass rod for use in screw machines; cartridge brass; cartridge brass disks; naval brass rods for structural purposes; sheet high brass; non-ferrous insect-screen cloth; portland cement; natural cement; CaO and $Ca(OH)_2$ for structural purposes and for use in the cooking of rags for paper manuf.; CaO for use in the manuf. of sulfite pulp; $Ca(OH)_2$ for the manuf. of varnish; CaO and $Ca(OH)_2$ for use in the textile industry, for the manuf. of SiO_2 brick, and for use in water treatment; gypsum; calcined gypsum; calcined gypsum for use in prepn. of dental plasters; Keene's cement; gypsum plasters for various uses; gypsum plastering sand, wall board, plaster board and partition tile; building brick; paving brick; clay sewer brick and pipe; clay fire brick for various uses; cement-concrete sewer pipe; drain tile; specifications and test for hollow burned-clay wall tile, floor tile and fireproofing, partition and furring tile; raw linseed oil; Perilla oil; gum spirits of turpentine; steam-distd. and destructively distd. wood turpentine; Zn oxide; leaded Zn oxide; basic carbonate and basic sulfate white leads; red lead; mineral Fe oxide; ocher; lithopone; lampblack; bone black; chrome yellow; pure chrome green; reduced chrome green; chrome oxide green; Prussian blue; ultramarine blue; com. para red; materials for cement grout filler for brick and stone block pavements; materials for cement mortar bed for brick, stone block, wood block, asphalt block and other block pavements; block for various types of granite pavement; gravel for bituminous concrete base; broken stone and broken slag for various uses for roads; sand for sheet asphalt and bituminous concrete pavements; high-C and low-C tar for surface treatment (hot and cold application); high-C and low-C tar cements; coal-tar pitch for stone block filler; gas and coking coals; foundry coke; structural wood; wooden paving blocks; asphalts and primer (for use with asphalt) for use in damp-proofing and waterproofing; high-C coal-tar pitches and high-bitumen coal-tar pitches for use in damp-proofing and waterproofing; high-C coal-tar pitch and high-bitumen coal-tar pitch for use in constructing built-up roofs surfaced with slag or gravel; creosote oil for priming coat with coal-tar pitch in damp-proofing and waterproofing; asphalt mastic for use in waterproofing; acid-resisting asphalt mastic; bituminous grout for use in waterproofing; woven cotton fabrics and burlap satd. with bituminous substances for use in waterproofing; asphalt roll-roofing surfaced with powdered talc or with granular talc; asphalt roll-roofing and asphalt shingles surfaced with mineral granules; asphalt-satd. and coal-tar-satd. roofing felts for use in waterproofing and in constructing built-up roofs; asphalt-satd. asbestos felt for use in constructing built-up roofs; air hose for use with pneumatic tools; wrapped cold-water hose; rubber gloves for elec. workers; rubber matting for use around elec. app. or circuits; rubber pump valves; friction tape for general use for elec. purposes; textile testing machines; tolerances and test methods for single and plied cotton yarns, for elec. cotton yarns, for cotton sewing threads, for certain light and medium cotton fabrics, for tire fabrics other than cord fabrics, for tire cord (woven and on cones), for elec. silk and cotton tapes and for asbestos yarns; tolerances for numbered cotton duck, for 23/5/3 carded American tire cord and for hose ducks and belt ducks; specifications and tests for Osnaburg cement sacks; A. S. T. M. partial-immersion thermometer for general use for various temp. intervals; sieves for testing purposes. *Standard methods* are given for: sampling rolled and forged steel products for check analyses; chem. analysis of plain C steel, of alloy steels, of ferro-alloys, of slab Zn (spelter), of pig Pb, of Ni, and of alloys of Pb, Sn, Sb and Cu; chem. analysis of Mn bronze, of gun metal, of brass ingots and sand castings and of bronze bearing metals; detg. wt. of coating on Zn-coated articles and on Sn, terne, and Pb-coated sheets; test for magnetic properties of Fe and steel; testing Zn-coated (galvanized) Fe and steel wire and wire products; sampling and chem. analysis of pig and cast Fe; sampling ferro-alloys; battery assay of Cu; test for resistivity of metallic materials for resistors; test for change of resistance with temp. of metallic materials for elec. heating; metallographic testing of Fe and steel and of non-ferrous metals and alloys; verification of testing machines; Brinell hardness testing of metallic materials; testing cement; chem. analysis of limestone, quicklime and hydrated lime; sampling, inspection, packing and marking of quick-lime and lime products; testing gypsum and gypsum products; making and storing compression-test specimens of concrete in the field; making compression tests of concrete; securing

specimens of hardened concrete from the structure; tests for unit wt. of aggregate for concrete, for detn. of voids in fine aggregate for concrete, for org. impurities in sands for concrete, for sieve analysis of aggregates for concrete, for approx. apparent sp. gr. of fine aggregate, for approx. percentage of voids in inundated fine aggregate, for surface moisture in fine aggregate, for refractory materials under load at high temps., for porosity and permanent vol. changes in refractory materials, and for softening point of fire-clay brick; ultimate chem. analysis of refractory materials, including chrome ores and chrome brick; sampling and testing turpentine; test for sp. gr. of pigments; test for coarse particles in dry pigments and coarse particles and skins in mixts. of pigments and vehicles; testing oleo-resinous varnishes; test for flash point of volatile inflammable liquids; routine analyses of white pigments, of white linseed oil paints, of dry red lead, of Ti pigments, of dry Cu_2O and of dry HgO; routine analysis of yellow, orange, red and brown pigments contg. Fe and Mn; routine analysis of yellow and orange pigments contg. Cr compds., blue pigments and chrome green; analysis for the color characteristics of paints in terms of fundamental phys. units; test for detn. of toluene-insol. matter in rosin (chiefly sand, chips, dirt and bark); abridged vol.-correction table for petroleum oils; analysis of grease; tests for burning quality of kerosene oils, of long-time burning oil for railway use, and of mineral seal oil; tests for C residue of petroleum products (Conradson C residue), for cloud and pour points of petroleum products, for detection of free S and corrosive S compds. in gasoline, for the detn. of autogenous ignition temps., for the distn. of natural-gas gasoline, for flash point by means of the Pensky-Martens closed tester, for flash and fire points by means of open cup, for m. ps. of paraffin wax and petrolatum, for sapon. no., for steam emulsion of lubricating oils, for S in petroleum oils heavier than illuminating oil, for thermal value of fuel oil, for viscosity of petroleum products and lubricants, for water in petroleum products and other bituminous materials, for water and sediment in petroleum products by centrifugal means, and for the distn. of gasoline, naphtha, kerosene and similar petroleum products; testing gas oils (sp. gr., distn., S, C residue, pour point, viscosity, water); tests for abrasion and toughness of rock and for apparent sp. gr. of coarse aggregates and of sand, stone and slag screenings, and other fine non-bituminous highway materials; decantation test for sand and other fine aggregates; test for quantity of clay and silt in gravel for highway construction; test for the detn. of moisture equiv of subgrade soils in the field; sampling stone, slag, gravel, sand and stone block for use as highway materials; mech. analysis of broken stone, broken slag, sand or other fine highway material or mixts. of materials, except aggregates used in cement concrete form of specifications for certain com. grades of broken stone; test for the detn. of bitumen; test for the detn. of proportion of bitumen sol. in CCl_4; tests for loss on heating of oil and asphaltic compds., for distn. of bituminous materials suitable for road treatment, for penetration of bituminous material, for softening point of bituminous materials (ring and ball method) and for softening point of tar products (cube-in water method); float test for bituminous materials; test for sp. gr. of road oils, road tars, asphalt cements and soft tar pitches; test for sp. gr. of asphalts and tar pitches sufficiently solid to be handled in fragments; sampling bituminous materials; sampling coal; lab. sampling and analysis of coal and coke; tests for fineness of powd. coal, for sieve analysis of crushed bituminous coal and of coke, for cu. ft. wt. of crushed bituminous coal and of coke, and for vol. of cell space of lump coke; shatter test for coke, tumbler test for coke; testing small clear specimens of timber; conducting static tests of timbers in structural sizes; sampling and analysis of creosote oil; tests for coke residue and distn. of creosote oil; chem. analysis of $ZnCl_2$; testing bituminous mastics, grouts and like mixts.; test for steam distn. of bituminous protective coatings, testing felted and woven fabrics satd. with bituminous substances for use in waterproofing and roofing; testing molded insulating materials, elec. porcelain, elec. insulating oils, rubber products and woven textile fabrics; verification of testing machines. *Recommended practices* are given for: annealing of rolled and forged C-steel objects; heat treatment of C-steel castings; carburizing and heat treatment of carburized objects, radiographic testing of metal castings; laying sewer pipe. *Standard definitions* are given for: terms relating to heat-treatment operations, to wrought-Fe specifications, to metallography, to methods of testing, to sp. gr., to lime, to the gypsum industry, to refractories, to sewer pipe, to hollow tile, to paint specifications, to materials for roads and pavements, to coal and coke, to timber and to textile materials; the terms sand and slate; clay refractories. *A standard rule* is given for governing the prepn. of micrographs of metals and alloys, including recommended practice for photography as applied to metallography. G. G

American Society for Testing Materials, Tentative Standards. 1930, 864 pp.

Tentative specifications are given for: steel track spikes; open-hearth Fe plates; steel marine-boiler plates; cold-rolled strip steel; heat-treated C-steel helical springs; C-steel locomotive forgings; elec. cast-steel stud-link anchor chain; austenitic Mn-steel castings; black and hot-dipped Zn-coated welded and seamless steel pipe; Zn-coated chain-link galvanized fence fabric; chilled-tread cast-Fe wheels; fire-refined Cu other than lake; Al-alloy (duralumin) sheet; Al-Mn alloy sheet; Al-base casting alloys in ingot form; Al-base and Mg-base alloy castings; sand castings of an alloy of Cu 80, Sn 10 and Pb 10%; Cu-base alloys in ingot form; seamless Cu tubing; tests for compressive strength of portland-cement mortars; high-early-strength portland cement; sand for use in lime plaster; gypsum sheathing board; concrete aggregates, building brick and pipe; fire tests of building construction and materials; boiled linseed oil; tung oil; soy-bean oil; petroleum spirits; glazier's putty; dry-bleached and orange shellacs; Al-bronze and Au-bronze powders; toxic ingredients in anti-fouling paints; sol. nitrocellulose; synthetic AmOAc, AmOH and Et lactate; EtOAc; BuOAc; BuOH; Bu propionate; com. sizes of broken stone, broken slag, sand and gravel for highway construction; broken stone for waterbound and bituminous concrete bases; $CaCl_2$ for dust prevention; asphalt cement of various penetrations and for various uses; high- and low-C tar cements for use cold in repair work; asphalt filler for brick pavements; mineral filler for sheet asphalt and bituminous concrete pavements; timber piles; wooden boxes of various constructions; asphalt for roof coverings; rubber insulating tape; insulated wire and cable; specifications and test methods for asbestos tape for elec. purposes; rubber-lined cotton fire hose; steam hose; tolerances and test-methods for rayon and for knit goods; tests for Cuban (jute) raw-sugar bags; chafer tire fabrics; thermometers for Engler viscometers. *Tentative methods* are given for: chem. analysis of Al, light Al alloys, rubber products and metallic materials for elec. heating; accelerated life test for metallic materials for elec. heating; test for thermo-elec. power; flexure tests of concrete; testing brick for compression, flexure and absorption; tests for resistance of fire-clay brick to thermal spalling action; tests for alky. or acidity, for bleeding, for hygroscopic moisture and for oil absorption of pigments; sampling and testing shellac, lacquer solvents and diluents; detn. of Me_2CO ext. in dry lampblack and bone black; test for detn. of polishing lubricant in Al powder for paints; sampling petroleum and petroleum products; tests for color of lubricating oils and of petrolatum by means of the Union Colorimeter; test for color of refined petroleum oil by means of the Saybolt Chromometer, tests for dilu. of crankcase oil, for distn. of crude petroleum, for expressible oil and moisture in paraffin waxes, for neutralization no. of petroleum products and lubricants, for penetration of greases and petrolatum, for pptn. no. of lubricating oils, and for vapor pressure of natural gasoline; test for gr. of petroleum and its products by means of the hydrometer; test for S in motor fuels, naphthas and illuminating oils; tests for abrasion of gravel, for consistency of portland-cement concrete, for ductility of bituminous materials and for residue of specified penetration; testing bituminous emulsions; test for size of anthracite; test for the detn. of the sp. gr., 38°/15.5°, of creosote fractions; test for coarse particles in bituminous materials by means of elutriation; testing asphalt roll-roofing surfaced with talc or mineral granules, likewise asphalt shingles surfaced with mineral granules; analysis of roofing felt for fiber compn.; compression testing of natural building stone; test for absorption and apparent sp. gr. of natural building stone; test for water absorption of slate; flexure testing of natural building stone and of slate; test for detg the insulating qualities of slate; testing insulating varnishes, cable splicing and pothead compds., insulating paper, laminated sheet insulating materials, and varnished cloths and tapes; testing sheet and tape insulating materials for dielec. strength; testing elec. insulating materials for power factor and dielec. const. at frequencies of 100–1500 kilocycles; test for comparing the thermal conductivities of solid elec. insulating materials; testing insulating materials for resistance to impact; test for resistivity of insulating materials; test for hardness of soft rubber; testing grease wool, etc., for scoured content; identification of textile fibers and their detn. in mixed goods; tension testing and compression testing of metallic materials. *Tentative recommended practice* is given for: bituminous-paving plant inspection; thermal analysis of steel. *Tentative definitions* are given for: terms relating to magnetic testing, to the gypsum industry, to refractories, to petroleum, to timber preservatives, to textile materials and to methods of testing; the terms aggregate, coke and screen (sieve). *Tentative rules* are given for inspection of concrete and reinforced concrete work. *Tentative revisions* are given of standard specifications for steel track spikes, structural steel for ships, alloy-steel bolting material for high-temp. service, high-test gray-Fe castings, chilled cast-Fe wheels, bronze bearing metal in ingot form, various types of condenser

tubes and ferrule stocks, portland-cement, hydrated lime for structural purposes, cement-concrete sewer pipe, broken slag for waterbound base and wearing course, shovel-run or crusher-run broken slag for waterbound base, block for various types of granite pavement, rubber pump valves, and tolerance and test methods for cotton fabrics; of standard methods of test for magnetic properties of Fe and steel, chem. analysis of Mn bronze, test for softening point of fire-clay brick, making and storing specimens of concrete in the field, testing woven textile fabrics, sampling and analysis of creosote oil, test for distn. of creosote oil, testing elec. insulating oils and testing rubber products; of standard definitions of the term sand, of terms relating to the gypsum industry, refractories, paint specifications, coal and coke, textile materials and methods of testing. G. G.

Standards and specifications for nonmetallic minerals and their products. JOHN Q. CANNON, JR. AND A. S. MCALLISTER. Bureau of Standards, *Miscellaneous Pub.* No. **110**, 680 pp.(1930).—Standards and specifications are given for: coal and coke; coal-tar products and bituminous materials; charcoal; petroleum and its products; fuel and illuminating oils; lubricating and insulating oils and greases; asphalt and other bituminous materials; stone and stone manufactures; sand, gravel and slag; sand-lime brick; gypsum and other plasters; magnesite; cement and concrete; lime; construction work; flat glass; glass containers; table glassware; lighting globes and shades; lenses; chem. glassware; mirrors; clay; china and porcelain ware; earthenware and stoneware; bricks and tiles; natural and artificial abrasives; asbestos; chalk; mica; rare minerals; precious stones and imitations; S; magnesia; salt; graphite; fluorspar and cryolite; feldspar; silica. G. G.

Specifications and materials control for aircraft construction. H. A. BACKUS *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 109–18(1930). E. H.

The relative merits of gas, oil and electricity for industrial purposes. P. HOPKINSON. *Gas World* **94**, Ind. Gas Suppl. 3(1931).—The subject is discussed from the viewpoint of the furnace engineer. F. H. BERGEIM

Wooden barrels in the chemical industry. II. LOUIS F. HORN. *Chem. Markets* **23**, 285–8(1931); cf. *C. A.* **25**, 1603. E. H.

Research in drying. M. LURJE. *Arch. Wärmewirt.* **12**, 21–3(1931).—L. gives very brief descriptions of the drying investigation of various German drier constructors, and of the Moscow drying lab. ERNEST W. THIELE

The process of evaporation. A. V. BLOM. *Farben-Ztg.* **36**, 873–5(1931).—The phys. laws governing evapn. are discussed. For single and mixed solvents, the rates of evapn. are expressed by the equations, $y = \alpha t^n$ and $y = \int_0^\infty \beta(a-y)dt$, resp., in which y = amt. of liquid evapd. in time t; a, the original amt. of liquid; α, β and n, consts. which depend upon the conditions of evapn. The value of α is independent of the presence or absence of non-volatile matter. G. G. SWARD

Industrial poisoning with aniline and similar substances. ANGELO BONZANIGO *Deut. Z. ges. gericht. Med.* **16**, 242–5(1931).—Cases are described of poisoning with aniline, nitro- and dinitrobenzene, nitrochloro- and dinitrochlorobenzene, phenylhydrazine and phenetidine and benzene. FRANCES KRASNOW

Poisoning with dilute tin chloride solution. R. ZEYNEK AND H. WAELSCH. *Deut. Z. ges. gericht. Med.* **16**, 184–9(1931). FRANCES KRASNOW

Carbon monoxide poisoning. H. HUG. *Deut. Z. ges. gericht. Med.* **16**, 72–88 (1931).—Case report. Discussion. FRANCES KRASNOW

Observations of carbon dioxide poisonings in the disaster at Neurode. G. W PARADE. *Deut. med. Wochschr.* **56**, 1385–8(1930).—Clinical observations were made after the mine disaster at Neurode. ARTHUR GROLLMAN

Comparison of heat-insulating materials for industrial furnaces and boilers. VICTOR PASCHKIS. *Arch. Wärmewirt.* **12**, 9–11(1931).—If k is the heat cond. of any substance, and p its price per unit vol., then for an infinite flat plate the most economical material (other things equal) is that which has the lowest value of kp. For actual solid bodies, especially furnaces of small dimensions, a higher power of k is required. In continuous use, k^2p does well; in most cases k^3p is still better as a discriminating quantity. ERNEST W. THIELE

Rosin in cable-impregnating compounds. J. P. MILLWOOD. *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 828–31(1930).—Saturants used to impregnate the paper windings around the Cu conductor of a cable have usually contained rosin or rosin oil or both, dissolved in petroleum oils or greases. The rosin serves to improve consistency and tack of the compd., secures more complete and lasting impregnation and better retention of the saturant, prevents "bleeding" when the ends are cut, prevents move-

ment of the saturant within the cable, and diminishes ionization troubles. The use of rosin, however, serves to limit the operating voltage and current loading of the cable contg. it, because of the low dielec. strength and high dielec. loss of rosin, causing the cable to become and remain hot when heavily loaded. When processed and blended with the proper oils, however, this effect is minimized. The use of rosin has been found to result in the formation of small, rather than large voids within the saturant. Small voids are preferred, because gas contained in them is less apt to ionize than gas in larger voids. Properties which rosin, to be used in cables, should possess are: (1) dryness, (2) absence of oxidized rosin, (3) freedom from dirt, turpentine and abnormally insol. rosin, (4) constancy of the above and other properties. H. K. SALZBERG

Separating liquids. A.-G., FÜR SPECIALBAUTEN. Swiss 142,335, Oct. 29, 1928. Addn. to 134,551 (*C. A.* **24,** 1684). App. is described for sepg. liquids lighter than water, *e. g.*, C_6H_6, from waste water.

Filtering alkaline liquids. ALUMINIUM-INDUSTRIE A.-G. Brit. 337,559, Jan. 17, 1929. See Ger. 502,430 (*C. A.* **24,** 4876).

Clarifying suspensions. ISIDOR TRAUBE. Ger. 517,055, Feb. 22, 1925. The settling of suspensions is accelerated by treating them in turn with a plant ext. such as carrageen moss and a salt of Ca or Sr, particularly $CaSO_4$. The treatment of ores is referred to.

Distillation of volatile substances. I. G. FARBENIND. A.-G. (Hans Franzen, inventor). Ger. 514,740, Feb. 9, 1928. In the sepn. of volatile substances from non- or difficultly volatile substances by distn. with a liquid whose b. p. lies below the distn. temp., part of the liquid is added, while the other part forms a heat-insulating layer between the liquid being distd. and the liquid about to be added. App. is described. The method is useful for refining oils and fats.

Solvents for cellulose esters and ethers, resins, fats, waxes and rubber. DEUTSCHE FARBENWERKE A.-G. Ger. 517,097, Nov. 27, 1928. Esters of cyclopentanone carboxylic acid with monohydric alcs. are used, alone or with other solvents, etc. The esters may be prepd. by treating esters of adipic acid with NaOEt.

Mixing materials for cement, pigment, fertilizer, acid phosphate or dye manufacture, J. H. MORROW (to Fuller Co.). Brit. 338,123, Oct. 3, 1928. In prepg. materials, as for cement manuf., blending is effected by passing the material from a mill cyclically to a plurality of "silos" or bins (a thin layer being successively added to the contents

of each of these) and by suitable withdrawal and redistribution of the material. Various details of app. arrangement are described.

Projecting hydrolyzable fluids such as titanium chloride into contact with air. JOHN T. REMEY. U. S. 1,792,929, Feb. 17. The fluid is discharged into the air (by a device which is described) simultaneously with a surrounding sheath of another non-reactive fluid such as dry air, CO_2 or CCl_4 in order to avoid clogging of the exit nozzle.

Gas filters for breathing purposes. GERHARD K. E. H. STAMPE (to Otto H. Dräger). U. S. 1,792,939, Feb. 17. Filters for removing NH_3 and H_2S are formed with Cu_2Cl_2 on a solid carrier substance such as activated charcoal treated with Pb nitrate soln.

Absorbent for ammonia in refrigerating apparatus. RALPH M. BUFFINGTON (to Frigidaire Corp.). U. S. 1,792,628, Feb. 17. $SrCl_2$ and NH_4NO_3 are used together. Cf. *C. A.* **25**, 1926.

Condenser (suitable for refrigerating apparatus). ROLLIN M. HYDE (to McCord Radiator & Mfg. Co.). U. S. 1,794,692, March 3.

Forming sheet insulating material such as wall board comprising a filter cake and associated deposit. FRANK W. YOUNG. U. S. 1,794,433, March 3. Materials such as fibrous pulps may be used and app. and various details of manuf. are described.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Sterilization of drinking waters at Saigon and at Cholon. J. GUILLERM. *Arch. inst. Pasteur Indochine* **1929**, No. 10, 36–55; *Chimie & industrie* **25**, 69(1931).—A description of the water supply, its treatment and control. The water, which is obtained from an underground sheet which is imperfectly protected from contamination by an overlying layer of clay of varying thickness and insufficient impermeability, is rendered perfectly safe by chlorination with bleaching powder at a cost of 0.0008 franc per m.³ Sterilization is controlled by counts of the aerobic and anaerobic bacteria, test for (and count of, if present) indole-forming *B. coli* and identification of other species of bacteria and protozoa. A. PAPINEAU-COUTURE

St. Louis has model water system. L. A. DAY. *Water Works Eng.* **83**, 731–2, 819–24(1930); cf. *C. A.* **24**, 5899.—This well-illustrated article with diagrams and statistics gives detailed descriptions of the equipment, treatment, operation and maintenance of the Chain of Rocks and the Howard Bend purification plants and their systems of distribution. C. H. BADGER

New York to rebuild century-old Croton Aqueduct as a safety measure. WM. W BRUSH. *Water Works Eng.* **83**, 736–8, 851(1930). A brief history of the old Croton Aqueduct is given and its present condition discussed. The daily demand on the municipal water system within the city is 900 m. g. d., while at times outside communities need 30 m. g. d. The yearly growth of demand will average 30 m. g. d. The present sources of supply are the Catskill system delivering 600 m. g. d., the New Croton Aqueduct, 280 m. g. d., and local sources of Long Island and Richmond, 120 m. g. d. To avoid a possible water shortage, since a new large source of supply will not become available for at least 6 or 7 years, the weak sections of the old Croton Aqueduct will be rebuilt so that its present delivery of 40 to 45 m. g. d. can be doubled. The probable cost will be between 1 and 2 million dollars and the work will be finished in 1931. C. H. B

Toronto constructing $14,000,000 tunnel. EARLE W. GAGE. *Water Works Eng* **83**, 654(1930).—The new filtered water tunnel, across the city, will follow the shore-line of Lake Ontario. It will be 7 ft. in diam. for more than 5 miles and 6 ft. in diam for nearly 4½ miles. The first section will deliver 90 m. g. d. into the heart of the city and 50 m. g. d. will be received at its western end. In addn., 60 m. g. d. will go directly into the city mains from high lift pumps at Victoria Park. A pure water reservoir here will hold 12,000,000 gal. and a new service reservoir in the northern part of the city will contain 50,000,000 gal. C. H. BADGER

Observations of water supplies of London and Paris. EDWARD BARTOW. *J. Am Water Works Assoc.* **23**, 267–71(1931).—In one of the plants visited excess lime treatment was used and the plant operation included lime recovery and removal of tastes and odors by activated C. In others compressed air for filter washing and ozone for purification were considered novelties. D. K. FRENCH

Unusual construction problems met in two Far Eastern water works. M. E. BARNES. *Water Works Eng.* **83**, 625–6, 658–61(1930).—Engineering difficulties in the

Far East are discussed. Every building in Bangkok, located 40 km. from the sea on the Menam Chao Phya River, is built on mud. This river carries enormous loads of silt and directly receives the sewage of Bangkok via its many canals and the pollution of many thousands who live in house-boats. Its chief objection as a source of water supply is that the water is made brackish from the flow of sea water past Bangkok upstream in the dry season. The water supply is taken from a natural reservoir created out of a branch stream 41 km. above Bangkok. A canal, policed to prevent diversion and pollution, carries the water to a modern water works erected on the outskirts of Bangkok. This plant contains sedimentation tanks, Jewell filters and equipment for distribution at an equalized pressure. It has proved its value in cholera outbreaks. By a suitably placed dam, a large catchment area located in that part of the Federated Malay States adjacent to the Island of Singapore was drawn upon for impounding purposes.

C. H. BADGER

Increasing supply of mountain city uncovers some unique problems. GEORGE D. NORCOM. *Water Works Eng.* **83**, 629-30(1930).—The water consumption of Bluefield, W. Va., has averaged about 1.2 m. g. d. Because of an 18 months' drought in 1925–6 the supply became inadequate. Since then the storage water capacity has been increased an addnl. 127 m. g. by construction of a dam and reservoir at the mouth of Horton Hollow. This reservoir now receives also the Gravity Springs supply which formerly was usually improperly chlorinated because of its remoteness and fed directly into the mains. The reservoir supply now flows by gravity to the Ada filtration plant, which also treats water obtained from a 45-m.-g. earth reservoir supplied by Ada Spring. The treatment consists of aeration, coagulation, sedimentation, rapid sand filtration and chlorination. Ada Spring is unusual because of its size and flow, which has varied from 0.175 m. g. d. to over 30 m. g. d. Provision was made against leakage through the soft limestone rock on which the new Horton dam was built by cleaning and grouting all weak spots in the rock and forcing cement grout into deep holes drilled into the rock to fill seams and crevasses. The Beaver-Pond-Bailey supply, which also was formerly chlorinated and pumped directly into the mains, has been retained as an auxiliary source in case of interruption to the Ada-Horton development. Daily chem. and bacteriol. tests are made for the control of purification.

C. H. BADGER

Water differences—geographically speaking. C. C. HUMPHREYS. *Southwest Water Works J.* **12**, No. 11, 15(1931).—H discusses unusual water conditions and turbidity, acid, Fe and phenol at Pittsburg, Pa., and algae at Ithaca. At Tampa, Fla., 300 p. p. m. color is removed by SO_2 and Cl_2.

O. M. SMITH

How the planets affect our water supply. CALEB M. SAVILLE. *Water Works Eng.* **83**, 735, 847-8(1930).—A general discussion is given of the long-period studies of climatology and meteorology. There is a greater tendency for rain in the quarter after full moon, especially with the moon in perigee, than with it in apogee. While the correlation between tree growth, as shown by tree rings, *e. g.*, the giant Sequoia, and climatic cycles seems to be definitely established, that between sun-spot phenomena and terrestrial climate has not as yet been accepted.

C. H. BADGER

Waterworks intakes and the screening of water. JOHN W. CUNNINGHAM. *J. Am. Water Works Assoc.* **23**, 258-66(1931).—The paper applies principally to flowing streams. For effective screening the design and arrangement of the intake are of great importance. Racks (intake screens (2 to 4 meshes per in.) and fine screens (8 meshes per in. or finer) are considered with reference to their best selection and location. Some reference is made to cleaning.

D. K. FRENCH

Water purification for color removal. A. S. BEHRMAN, R. H. KEAN AND H. GUSTAFSON. *Paper Trade J.* **92**, No. 8, 121-3(1931).—Modern methods of color removal are briefly reviewed, and results are given of an investigation into the nature of the coloring matter in water and new methods of removal based thereon. It was found that: (1) The particles of coloring matter are negatively charged. (2) The particles of coloring matter are of a colloidal nature, though some of them may approach mol. dimensions and consequently be in true soln. (3) The coloring matter in surface waters is essentially org. in nature. (4) In many cases the color deepens considerably with increase in p_H of the water, particularly when passing from acid to alk. conditions. (5) The color is destroyed to a considerable, but variable, extent by chlorination. The excess Cl must be removed after destruction of the color in order to prevent corrosion; and with all the waters tested it was found that dechlorination by filtration through granular hydrodarco removed not only the Cl, but also the whole of the residual color. Filtration through hydrodarco, without previous chlorination, removed all or nearly all the color; but owing to the necessity of revivification, it is usually more economical to remove as much color as possible by coagulation and filtration under carefully controlled

p_H conditions, followed by chlorination and then dechlorination if necessary. An attempt is being made to find a method of revivification that will be so simple as to make it practical and economical to decolorize the water directly by treating with hydrodarco, without preliminary coagulation, filtration or chlorination. A. P.-C.

Treatment of water for ice manufacture. DANA BURKS, JR. Univ. Ill. Eng. Expt. Sta., *Bull.* No. 219, 114 pp.(1930).—This work done in coöperation with the Utilities Research Commission embraced a study of methods for producing clear ice from natural waters high in dissolved salts, particularly Na_2CO_3 and $NaHCO_3$. With neutralization of the water with alum or H_2SO_4 to convert the carbonates to the less troublesome sulfates and with the use of a specially designed ice can providing ample and effective air agitation, a marketable ice fairly free from opaque zones was produced If, however, the core water reaches a critical concn. of salts it must be replaced with a new supply. A second line of attack involved the utilization of the exchange properties of Mg zeolite to replace Na salts in the water with the equiv. Mg compds. Subsequent liming, followed by alum or acid treatment, produced from $NaHCO_3$ water supplies one from which satisfactory ice could be made. H. L. OLIN

Galvanized iron pipes for city water supply. J. DE GRAAFF. *Verslag. Mededeel. betreffende Volksgezondheid*, July 1930, 8 pp.—The requirements for galvanized iron piping are discussed. It should be nonporous. A test for porosity of the Zn coating is to pour a 10% gelatin soln. with 1% $K_3Fe(CN)_6$ on a part of the inside of the pipe which has been cut in half. After 24 hrs. at room temp. blue spots in the solidified gelatin indicate breaks in the coating. The thickness of the Zn layer should be sufficient. It is detd. by dissolving the Zn in HCl (d. = 1.2) to which 20 g. Sb_2O_3 per l. has been added. This acid does not attack Fe. A simple app. for the detn. is described: a 2- to 3-cm. Cu tube, 3 cm. long, is filed off to fit the inside of half of the galvanized pipe. Proper sealing is obtained by pouring asphalt around the Cu pipe. Acid is poured in through a funnel in one hole of a double-bore stopper closing the Cu pipe, H_2 evolved escapes through the other hole and is collected and measured in a bottle. A min. of 600 g. Zn per sq. m. of galvanized surface (one side) is required. The Pb content of the Zn used should be less than 0.5%. On the nature of the water depends whether the Zn will be effective in reducing corrosion. If the water causes a $CaCO_3$ deposit after some time, the corrosion chances will be diminished. If no $CaCO_3$ is deposited, the Zn will dissolve in time and corrosion take its course. From an example is shown that in water of low hardness as much as 3.9 mg. Zn per l. is present after standing 1 night in galvanized piping. Water left for 36 hrs. in a new pipe even had 7 mg. per l. Zn gives at best a temporary protection. B. J. C. VAN DER HORVEN

Subsoil management, particularly from the viewpoint of water mains. BRABANT, MOYAERTS, *et al.* *L'eau* **24**, No. 1, 5–8(1931). C. R. FELLERS

Why water mains break. FRANK A. MCINNES. *Water Works Eng.* **83**, 559–60, 589(1930).—Rigid bearing, or uneven settlement of the supporting ground, electrolysis, earthquake, frost, effect of salt-marsh land and abnormal chem. character of the pipe itself are some causes given for the fracture of cast-iron pipes. C. H. BADGER

Iodine content of Lettish waters in relation to the improvement of crops. J. KUPCIS. *Acta Univ. Latiensis Kim. Fakultat. Serija* **1**, 425–48, 449–53(in German) (1930).—K. gives complete analyses for 61 samples of Lettish waters and discusses the sources of the I in the various samples. He discusses the need of I in growing crops and points out various causes for the decrease in the amt. of available I. C. J. WEST

Detailed instructions for the performance of the dissolved oxygen and biochemical oxygen demand tests. EMERY J. THERIAULT. *U. S. Pub. Health Repts. Suppl.* No 90, 34 pp.(1931). J. A. KENNEDY

Method of determination of the chlorine demand of any water. D. K. PATTILLO AND F. D. WEST. *Paper Mill* **54**, No. 5, 4(1931).—Cl demand is defined as the amt of Cl that will combine chemically, or possibly biologically or bacteriologically, with any given water, white water or sewage to so change the state of oxidizable matter that it will not require addnl. O. The method consists essentially in titrating 500 cc. of the sample with hypochlorite soln. contg. 0.0001 g. available Cl per cc. until a blue color is obtained with iodized starch soln. used as outside indicator, adding a further slight excess of Cl and then detg. the residual Cl with a standard colorimetric Cl-testing outfit A. PAPINEAU-COUTURE

Early use of chlorine. WM. BOBY. *J. Am. Water Works Assoc.* **23**, 283–4(1931). A paper published earlier is discussed. The equipment used as well as the results obtained in the first Belgium installation in 1902 are described. The process employed was invented by Dr. Maurice Duyk, official chemist to the Belgian Govt. D. K. P

Progress in superchlorination treatment for taste prevention at Toronto, Ontario.

N. J. HOWARD. *J. Am. Water Works Assoc.* **23**, 387–95(1931).—See *C. A.* **24**, 4878. G. G.

Preammoniation of the filtered water supply of Cleveland, Ohio. J. W. ELLMS. *J. Am. Water Works Assoc.* **23**, 400–7(1931).—See *C. A.* **24**, 4878. G. G.

Eijkman test for the bacteriological examination of water. MARIO MAGALHAES. *Arch. hyg. Rio de Janeiro* **4**, No. 2(1930); *U. S. Pub. Health Eng. Abstracts* **11**, W, 19(Feb. 21, 1931).—Eijkman's method employs a glucose peptone medium, to which the water under examn. is added in the ratio of 1:8 and incubation carried out at 46°. In 18–24 hrs. a distinction can be made between *B. coli* from cold- or warm-blooded animals. In addn. to being selective for *B. coli*, it inhibits common water organisms and bears a correlation with the tests of indole production, the citrate and uric acid reaction, and may thus prevent contamination of water when *B. coli* are of non-human or cold-blooded origin. C. R. FELLERS

Dental deficiencies and drinking water. R. W. KEHR. *J. Am. Water Works Assoc.* **23**, 214–29(1931).—A dental defect, known generally as mottled enamel, is described, and the location of communities in which it is found is mapped. It is thought to be due in some way to the drinking water used by the victims. No explanation can be given at the present time. D. K. FRENCH

Lead poisoning from drinking water in Leipzig. KRUSE AND M. FISCHER. *Deut. med. Wochschr.* **56**, 1814–8(1930).—A clinical account is given of a recent epidemic. ARTHUR GROLLMAN

Water supply of a steel plant. T. J. MCLOUGHLIN. *Proc. Eng. Soc. West Penn.* **46**, 295–305(1930).—Extremely large vols. of water are necessary, one ton of steel requiring 14,000 to 17,000 gallons water. The main intake of a steel plant is one of the most vital spots. Extreme care is exercised to prevent injury by floating débris and ice. Modern variable-speed traveling screens insure freedom from floating material. Much of the water in an iron region, especially the Pittsburgh district, periodically contains considerable free H_2SO_4. A considerable portion of the water must be neutralized with milk of lime to prevent corrosion of the distribution system. Boiler-feed water usually is treated river water. A few of the smaller plants use a hot lime-soda process; some use a continuous cold lime-soda treatment; a few are zeolite plants, but by far the most use an intermittent lime-soda process followed by filtration. Internal treatment is rapidly becoming recognized as an economical and effective method of scale prevention. WAYNE L. DENMAN

Softening a well-water supply. N. T. VEATCH, JR., AND B. L. ULRICH. *J. Am. Water Works Assoc.* **23**, 272–5(1931).—The Manhattan, Kans., supply is softened by lime and alum. With chem. softening alone a hardness of 463 p. p. m. was reduced to 165 p. p. m. With recarbonation in addn. this was lowered to 124 p. p. m. D. K. F.

Water supply for high-pressure boilers. CHAS. R. HAZEN. *Pulp Paper Mag. Can.* **31**, 195–8(1931).—The formation and effects of scale and the factors favoring corrosion are briefly reviewed, and the usual processes of water softening are outlined. They do not furnish a water suitable for the very exacting requirements of high-pressure boilers. The prime essential of such boilers is clean evapg. surfaces; this can be obtained by the properly controlled addn. of NaH_2PO_4, either in the boiler or before feeding, and with or without a preliminary softening treatment according to the nature of the raw water. A. PAPINEAU-COUTURE

Boiler-scale prevention by the use of trisodium phosphate in modern boiler management. PAUL KOEPPEL. *Chem.-Ztg.* **55**, 58–9(1931).—Na_3PO_4 is the ideal softener for use in modern high-pressure boilers. It is inexpensive and efficient and requires no special equipment to add the softener. Contact during only 1 hour at 70° is required to cause pptn. of the Ca and Mg salts. C. R. FELLERS

Developments in the treatment of acid mine drainage. LEWIS V. CARPENTER AND ALFRED H. DAVIDSON. *Bull. West Va. Univ. Sci. Assoc.* **2**, No. 4, 50–7(1930).—The acidity from coal-mine drainage has created a serious problem in West Va. The amt. of drainage is approx. 25% of the rainfall. Ordinarily the flow of mine drainage will be 1000 gal. per day per acre of coal exhausted and is independent of the nature of the season. The acidity cannot be predicted, as often one mine will give an alk. drainage, while another nearby will be highly acid. The conversion of S to acid is rapid and is hard to explain by the chem. process of oxidation. Some hold that the action of anaerobic bacteria is responsible. Treatment has consisted of the addn. of powd. lime, limy marl, limestone and magnesite, but is not used to much extent practically. The Kaplan-Reger process is said to remove all chemicals in the water, forming a blue pigment, but little is known about it. Very little is known concerning the details for proper disposal by dilution. On a cost comparison basis, limestone is the cheapest. If allowance is

made for capitalized cost of the plant, drying of sludge and no return for sale of sludge, the total cost per 1000 gal. is $0.90. At this cost the process is not feasible. To be successful, the process must allow disposal of the by-products. WAYNE L. DENMAN

Eliminating odors and nuisances about the sewage-disposal plant. F. R. HASSLER. *Southwest Water Works J.* 12, No. 10, 17(1931).—The use at Perry, Okla., of NH_3 3 to 7 lbs. per million gals. together with an av. of 25 lbs. of Cl_2 in domestic sewage preceding digestion in sep. sludge digestion tanks removed H_2S odor and produced a stable effluent. O. M. SMITH

Reclamation of treated sewage. R. F. GOUDEY. *J. Am. Water Works Assoc.* 23, 230–40(1931).—By reclamation is meant treatment of such a high grade of efficiency that the water as well as the solids can represent credits in water supply economy. In Southern California this need of reclamation is of the utmost importance. While some work has already been done, much more is necessary before all its difficulties are overcome. D. K. FRENCH

Digestion of sewage solids at high temperature. THEO. F. DOZORS. *Munic. Sanitation* 2, 121–4(1931).—Samples of fresh sewage solids seeded with ripe sludge were digested at the thermophilic temp. of 55° and at room temp. Detns. of the nature and quantity of gas evolved, p_H, dry solids, ash, volatile matter and no. of bacteria were made upon duplicate samples. Thirty days was the optimum digestion period. From 18% to 20% more gas was evolved from solids digested at thermophilic temps. than at room temp. CO_2, O, CH_4 and N were present. The CH_4 and CO_2 contents fluctuated inversely. Gas produced in either case was 65–75% combustible. A p_H of 7.3 was the optimum for digestion at thermophilic temps. Total bacteria present and solid detns show little difference under the 2 conditions. GILBERT L. KELSO

Utilization of sewage gas. H. F. KUISEL. *Monats-Bull. Schweiz. Ver. Gas-Wasserfach.* 10, 293–8(1930).—Sewage gas from settling tanks of the city of Zurich (700,000 m.³ annually) contained 66% of very pure CH_4 (30% CO_2, N_2 and a trace of H_2S). Possibilities for the utilization of CH_4, chlorination, oxidation, conversion into fuel oil, etc., are considered in the light of recent patent literature. K. H. ENGEL

The mechanism of the activated-sludge process of sewage disposal. E. C. C. BALY. *J. Soc. Chem. Ind.* 50, 22–6T(1931).—The sign of the elec. charge on sewage colloids can be detd. by flocculation of suspensions of fine powders of known charge and by means of cataphoresis. Both methods indicate that sewage colloids behave as if they were electropositive when the p_H is less than 8.3 and electronegative when it is over 8.3. Sewage colloids have an isoelec. point at about p_H 4.6 which shifts toward the side of greater p_H in the presence of electrolytes. The colloids in ordinary sewage with p_H 7.4 are therefore electronegative. The bacteria of sewage carry an electronegative charge, and when their concn. is sufficient they are flocculated by electropositive colloids. When their concn. is insufficient they exist as bacteria and colloid complexes, when the colloids are electropositive. The success of the activated-sludge process is due to the much enhanced charge on the bacteria when in their state of max. activity. The necessity for this max. activity would disappear if the colloids were electropositive and operation of the process is proposed at p_H 5.8–6.0. W. H. BOYNTON

Advantage of sludge circulation and vacuum degasification as applied at the Cleburne plant. CLYDE C. HAYES AND CHESTER COHEN. *Proc. 12th Texas Water-Works Short Course* 1930, 161–6; *U. S. Pub. Health Eng. Abstracts* 11, S, 20–1(Feb. 14, 1931); cf. *C. A.* 24, 3301.—The Cleburne plant consists of a grit chamber, Imhoff tank with central gas vent, dosing chamber and Miller siphon and a sprinkling filter unit. Inadequate sludge digestion capacity, 0.5 cu. ft. per capita, foaming difficulties, odor troubles, filter bed clogging and inadequate purification of the effluent were some of the difficulties of operation formerly. Some of the theories advanced for the present hastened digestion with degasification and sludge circulation are: (1) That through the circulation of the digested sludge the end products which are inhibitory to bacterial life and are produced through decompn., are effectively removed in the form of gases distributed through the tank liquor (2) thorough and continuous mixing of the ripe and fresh solids aids in speeding digestion and maintaining a desirable H-ion concn. and secures a thorough mixing of the bacterial flora of the sludge; (3) the entrained gases are more easily liberated through the stirring action and more quickly carried off through the vacuum maintained on the gas vents; (4) the reduction of the gas concn. in the top area of the gas vent through the use of the vacuum system decreases pressure of the gas through the entire body of the liquid; (5) the maintenance of the vacuum on the gas vents serves to further increase the efficiency of the Imhoff slot, and thus tends to prevent belching of solids upward into the sedimentation compartment; (6) the scum and foam which usually accumulate on the top of the gas vents can be mechanically drawn off, at

least partially digested, which saves addnl. labor cost incidental to this process; (7) in spite of the reduced sludge-digestion capacity the tanks are producing a fairly well digested sludge which can be discharged on drying beds, without any fear of odor nuisance or fly breeding. While economic use of captured gas is not considered, as the primary function of the plant is sewage purification, a 4-hp. gas engine can be successfully operated from the sewage gas. Complete details of plant operation are given with description of plant units. Conclusions: The vacuum system of degasification and sludge circulation demonstrated the following advantages: (1) Continuous circulation of the digesting sludge is advantageous in hastening the process of org. decompn.; (2) the circulation of the sludge through the use of the vacuum pump is most economical and satisfactory; (3) the putrefactive odor from the Imhoff tank is entirely controllable; (4) foaming difficulties are avoided; (5) labor cost for scum removal and gas vent control is practically eliminated; (6) the reduced size of tank made possible through this vacuum system and sludge circulation will decrease the cost of Imhoff tank construction, greatly simplify and reduce operating expenses and minimize legal complaints. C. R. FELLERS

The role of protozoa in activated sludge. ROBERT CRAMER. *Ind. Eng. Chem.* **23**, 309-13(1931); cf. *C. A.* **24**, 2819.—Clarification of sewage can be accomplished by aeration if aerobic bacterial life, live protozoa and oxygen in soln. are present. The biochem. nature of the process is indicated. Material decompd. by aerobic and anaerobic bacterial life in sewage would remain in a colloidal, non-settlable state if the protozoa did not resynthesize it. F. W. TANNER

Lagooning sludge. EDGAR WHEDBEE. *Proc. 12th Texas Water-Works Short School* **1930**, 153-6; *U. S. Pub. Health Eng. Abstracts* **11**, S, 18(Feb. 14, 1931).—The sewage-disposal plant at Dallas, Texas, lagoons the sludge drawn from the digestion chambers of the Imhoff tanks as well as scum from gas vents and ski nmings from the surface of the flow chambers or settling basin. During extended rainy weather the sludge beds were filled and the digestion compartments became overloaded, and, when accompanied by foaming, became large septic tanks. The difficulty was remedied by running the excess sludge into a shallow slough or lagoon nearby. No odors came from the lagoon. The yield of wet sludge per million gals. was 7.6–8.0. C. R. FELLERS

Determination of carbon in sewage and industrial wastes. F. W. MOHLMAN AND G. P. EDWARDS. *Ind. Eng. Chem., Anal. Ed.* **3**, 119–23(1931).—The C detn. of Friedemann and Kendall (*C. A.* **23**, 2733) has been applied to domestic sewage and trade waste and can be completed in 3 hrs. *Results with carbohydrates, soap and amino compds.* indicate satisfactory accuracy for the purpose. When org C/total N on raw sewage, corn products, stockyards and tannery wastes is 3.96–42.7, org. C/biochem. O demand is 0.55–0.65. This indicates a relation between org C and 5-day O_2 demand and supports the theory that the first stage of the O_2 demand curve is a C oxidation. An activated-sludge effluent is in a different stage of oxidation and cannot be directly compared, the corresponding org. C/biochem. O demand being 4.1. FOSTER DEE SNELL

Precautions needed in the ammonia-chlorine treatment of swimming pools. A preliminary study. LYLE L. JENNE AND HENRY R. WELSFORD. *Ind. Eng. Chem.* **23**, 32–4(1931).—The use of chloramine for sterilization makes possible a high residual Cl content without the unpleasant taste, odor or irritating effects of free Cl. With the recirculation of swimming pool water as generally practiced, the NH_3 content is cumulative and reduction to NO_2^- occurs in certain concns. These products interfere with the color test for available Cl. Use of an antichlor will destroy chloramine. Excess color formed under such conditions should be ignored when considering Cl values for sterilization. The apparent fallacy of this treatment should not outweigh its advantages. EDWARD S. HOPKINS

Creoline as a larvicide. DURRN. *Ann. soc. belge méd. trop.* **8**, 23–5(1928); *U. S. Pub. Health Eng. Abstracts* **11**, Ma, 2(Feb. 14, 1931).—Lab. expts. made with heavy tar oil showed 200 p. p. m. was the min. effective dosage to prevent mosquito breeding.

The oil must be applied every 10 days. It is of particular value in shallow pools rather than in deep water. C. R. FELLERS

Progress in the treatment and disposal of human wastes. R. E. MCDONNELL. *Munic. Sanitation* 2, 114–8(1931). G. L. KELSO

Treating of canning wastes. ANON. N. Y. State Dept. Health, Div. Sanitation, *Bull.* (unnumbered) 1930, 100 pp.; *U. S. Pub. Health Eng. Abstracts* 11, S, 19–20(Feb. 14, 1931).—Analytical data are tabulated in 28 tables. Suggested treatment plant designs are given. Conclusions: Screening through wire screens having 20 to 40 meshes to the in. is a necessary preliminary treatment in all cases and adequate treatment when the final diln. is greater than 1 to 100. Forty sq. ft. of effective screen area is necessary for a 2-line cannery discharging 100,000 gal. of wastes per working day of 12 hrs. About 80 cu. ft. of screenings are produced per 100,000 gal. of wastes treated. Trickling filters are very effective in the treatment of screened canning wastes when the rate of filtration is less than 0.5 million gal. per day throughout the working day, and this treatment is adequate when a final diln. is greater than 1 to 5. Rates of filtration of 2 million gal per day throughout the working day are sufficient when the final diln. is greater than 1 to 20, provided serious pooling is prevented through the periodic application of lime to the applied wastes to prevent the prolific growth of fungi on the filter. Chem. pptn. of canning wastes with 7–10 lb. of lime and 3–5 lb. of $FeSO_4$ per 1000 gal. of wastes is sufficient treatment when the final diln. is greater than 1 to 25. Although the cost of constructing chem. pptn. equipment may be less than that of trickling filters, nevertheless the cost and difficulty of operation, cost of chemicals and the less satisfactory effluent justify the use of trickling filters in most cases. Final chlorination of filtered or coagulated and pptd. canning wastes modifies the org. matter and is equiv. to the removal of about 30% of the residual unstable org. matter. Final chlorination, therefore, permits of the discharge of filtered canning wastes into streams with final dilns. as low as 1 to 3, provided the rates of filtration of 0.5 million gal. per day are used. Final chlorination of filtered or coagulated canning wastes also materially reduces or entirely suppresses the fungus growths in the streams receiving the effluent, thus eliminating an objectionable result of pollution. The required dose varies from 8 to 30 p. p. m. Cl depending upon the degree of preliminary treatment of the wastes to assure a residual of at least 0.5 p. p. m. in the effluent. Every effort should be made to reduce the water consumption of canneries and to prevent the wastage of the product so as to reduce the strength and quantity of wastes to be disposed of. The relatively high cost of treating these wastes, which are 5–15 times as concd. as raw domestic sewage, makes it very desirable that efforts be made to recover by-products from the wastes and thereby reduce the net cost of their disposal. C. R. FELLERS

Treatment of tannery wastes (ANON) **29.** Corrosion of steel water pipes by stray electric currents (ROTHE) **9.** Titrimetric determination of small quantities of NH_3. KLUT, HARTWIG: **Untersuchung des Wassers an Ort und Stelle.** 6th ed. Berlin J. Springer. 180 pp. M. 7.80.

Apparatus suitable for filtering water through sand, etc. HAROLD D. ELFRETH (to Cochrane Corp.). U. S. 1,794,841, March 3. Structural features.

Softening water with base-exchange material. GEORGE BORROWMAN. U. S. 1,793,670, Feb. 24. The water is percolated through a granular bed comprising lignite or brown coal contg. an exchangeable alkali metal until the latter is "more or less exhausted," and the bed is then revivified by percolating a NaCl soln. through it and washing it, and is then further used for water purification.

Base-exchange compounds. GENERAL ZEOLITE CO. Brit. 337,768, July 27, 1929. Reaction is effected between an alk. metal silicate, an alk. compd. of an amphoteric hydroxide and a non-alk. compd. of an amphoteric hydroxide, to form a gel including substantially the whole reaction mixt.; *e. g.*, a soln. of Al sulfate contg. added H_2SO_4 is mixed with a Na silicate soln. and a soln. of Na aluminate is added. An acid or caustic alkali or both may be added to the reaction mixt. and the use of Na zincate and other materials is also mentioned. The gel may be dried and washed. Cf. *C. A.* 24, 909.

Water-softening apparatus. WALTER H. GREEN (to International Filter Co.). U. S. 1,794,765, March 3. Various structural details are described of an app. operating with a layer of zeolitic material superposed on a layer of non-zeolitic material such as gravel.

Domestic water vessels containing base-exchange material for softening water placed in them. E. Brenil and Établissements Phillips & Pain. Brit. 338,021, Dec. 2, 1929. Various modifications are described of an app. of the general character of that described in Brit. 295,004 (*C. A.* **23**, 1978).

Apparatus for purifying boiler feed water by sedimentation, etc. Edward J. Brock. U. S. 1,794,395–6, March 3. Various structural details are described.

Preventing furring. Jean Schnebbeli. Swiss 141,897, May 24, 1930. Furring is prevented in water heaters by addn. of H_2CrO_4 and a colloid. In the example, an aq. mixt. of H_2CrO_4 and colloidal SiO_2 is added. Cf. *C. A.* **25**, 760.

Preventing furring in boilers. Fritz Hackenbruch. Ger. 514,816, Dec. 3, 1926. Colloids are added to the water which is then made to deposit its fur, by heating under pressure, before admission into the boilers.

Distributor box for sewage-disposal system. John F. Harris. U. S. 1,795,123, March 3.

Settling tank for removing sludge from sewage. Gustav R. Roddy (to Chain Belt Co.). U. S. 1,795,143, March 3.

Apparatus for conditioning air with water sprays, etc. A. T. Lewis, H. P. Gant and R. R. Taliaferro. Brit. 338,018, Nov. 28, 1929. Structural features.

Treating waste liquors to remove sulfidic sulfur. Courtaulds, Ltd., R. S. Jones and S. Pearson. Brit. 337,533, Sept. 23, 1929. The liquor is first treated with acid until neutral or very slightly acid, in the presence of the SO_2 radical, as by the use together of $ZnSO_4$ or $MgSO_4$, $NaHSO_3$ and H_2SO_4, and on mixing the materials part of the S settles out. The remaining liquor is then treated with caustic alkali in the presence of a Zn or Mg salt until it is alk. to phenolphthalein, when $Zn(OH)_2$ or $Mg(OH)_2$ and the rest of the S settle out.

Recovering oil from waste water. Fioravante Cattelan. Swiss 140,639, Sept. 4, 1929. App. for the sepn. of C_6H_6, oil and petroleum from waste water, including a revolving drum with internal compartments, is described.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER AND M. S. ANDERSON

Summary of results of German soil analyses up to 1929. Liehr. *Z. Pflanzenernähr. Düngung u. Bodenk* **9B**, 337–9(1930).—The degree of soil acidity and the P_2O_5 and K_2O contents are given in tabular form. H. B. Siems

The temperature correction in the hydrometer method of mechanical analysis of soils. Charles Richter. *Soil Science* **31**, 85–92(1931).—A study is made of factors affecting the mech. analysis of soils by use of a hydrometer. Soil suspensions of a particular soil at different concns. but at the same temp. will not give identical results when the temp.-correction factor of 0.35 is applied at all concns. Concordant results are obtained only when the correction applied is considerably smaller at the lower range of the hydrometer than at the higher range. A sliding-scale correction table is suggested. M. S. Anderson

Variation of the colloidal material extracted from the soils of the Miami, Chester and Cecil series. R. S. Holmes and Glen Edgington. U. S. Dept. Agr., *Tech. Bull.* 229, 1–23(1930).—A specially designed agitator is described in which the soil suspensions were prepd. A 75% sepn. of the colloidal material from these suspensions was obtained by means of a supercentrifuge. The colloids derived from the various samples of each series show a marked constancy, but they show an equally marked divergence between the different series. The largest amt. of colloidal matter is found in the B horizon. The H-ion concn. is on the acid side in all but 1 horizon. With few exceptions the org. matter, S and P are most abundant in the A horizon. SiO_2 increases with depth in most of the Chester profiles, whereas the reverse is true for the Miami and Cecil series. The active base constituents vary in the Miami profiles in the reverse order to their variations in the Chester and Cecil profiles. The Fe_2O_3 content is higher in the lower horizons of all 3 profiles. The relative constancy in compn. of the colloids of each series is calcd. and discussed. The colloids of the different soil series are, in general, very different. If the series are arranged in the order of the $SiO_2:R_2O_3$ ratio the order becomes Miami, Leonardtown, Chester and Cecil. This order also generally holds for the 4 major constituents if the reciprocal character of the relation is kept in mind. Combined H_2O varies inversely with the $SiO_2:R_2O_3$ ratio. The univalent and bivalent bases do not follow this ratio very closely. J. R. Adams

Interaction between ammonia and soils, as a new method of characterizing soil colloids. AMAR NATH PURI. *Soil Science* 31, 93–7(1931).—Soils react very slowly with bases. Equil. conditions can be reached quickly only when a large excess of alkali is added and the excess removed by leaching or by pptn. as some insol. compn. Completely unsatd. soils will combine with an amt. of NH_3 which may be considered equiv. to the base-exchange capacity. The method used for NH_3 adsorption consists of placing the H-satd. soil in a flat dish in a vacuum desiccator over *N* NH_4OH for 2 days. The dish is then removed and placed over 90% H_2SO_4 in vacuum for 48 hrs. The NH_3 retained is detd. by distn. with lime. The p_H values of soils contg. $CaCO_3$ are about the same after dil. acid treatment and subsequent NH_3 satn. as for the soil in the natural condition. M. S. ANDERSON

Investigations on the organic matter of soils. Their determination and their importance as nitrogen reserves. VINCENT, HERVIAUX AND GAUDIN. *Ann. sci. agron.* 47, 654–71(1930).—Humic materials extd. from a soil vary with the chem. nature of the alk. solvents, their concn., the temp. and the reaction time. The concn. of the alk. soln used affects the concn. of the humus. High alk. concns. break down humic material and too weak solns. produce variable results. The humic materials and humus reduce 0.1 *N* K permanganate solns. in a fairly const. manner. The combinations of N and their probable role in soil fertility are summarized. The necessity of stating precisely, in soil analyses, the existing humic and N combinations is emphasized. The detection and detn. of humic materials are essential. The humate solns. obtained were analyzed for total and sol. humic materials by oxidation by K permanganate. If it is wished to study the ammonification of sol. org. materials, the extn. in the cold for a protracted time with a weak, alk. soln. is preferable. It is advised that 20 g. of finely ground, decalcified soil be agitated mechanically for 2 hrs. with 500 cc. of 1% soda soln followed by 24 hrs. standing with occasional shaking by hand. F. W. MARSH

Some methods for detecting differences in soil organic matter. EDMUND C. SHORBY. U. S. Dept. Agr., *Tech. Bull.* 211, 1–25(1930).—The dark color of the alk. exts. of soils is not due to the absorption of O during the process of extn., and such color cannot be considered an indication of the presence of phenolic compds. Differences in the shades of color of humus exts. are proof of differences in the kind of org. matter, but a comparison of the depth of color of the exts. cannot be used as a measure of the quantity of org. matter present. The N in the various fractions of an alk. ext of a soil and the quantity of O absorbed when air is passed through the ext. vary with the soil. The presence of 2 classes of org. nitrogenous compds. in soils is indicated. These are chitin and its deriv., glucosamine, and some member of the indole group. The results of acid hydrolysis of soils from a N standpoint and the use of alc., water and alternate alc. and water extn. are discussed as means of showing differences in soil org. matter. The formation of azophenine when some soils are heated with $PhNH_2$ is described, and this formation is suggested as a means of showing the presence or absence of some as yet unknown org. soil constituents. A short discussion of a no. of general reactions that may be applied to soil exts. or fractions, such as the pyrrole and fluorescin reactions, are presented. W. H. ROSS

The replaceable cations in the soil and the plant. K. K. GEDROIZ. *Udobrenie i Urozhai* (*Fertilizers and Crops*) 2, 464–75(1930).—A chernozem soil was satd. with the cations, Mg, Ba, Mn, Co, Ni, Cu and H. It was used in pot expts.—700 g. per pot—on mustard with a complete fertilizer and without. No crop was obtained with any one of the enumerated cations. In another series of expts., with the same soils, 10 g. $CaCO_3$ was added, and the exptl. plant was oats. No crop was obtained from Ba, Ni and Co soils. A small crop was obtained with the Cu soil (0.39 g. of dry matter against 5.4 g on the regular chernozem soil with $CaCO_3$), a slightly better crop—1.56 g.—from the Mg soil, and 1.6 g. from the Mn soil. The H soil gave a normal crop. The next series of expts. was conducted with solid satd. with Mg, Ca, Sr, Cd, Fe^{++} and Fe^{+++}, Al and H. All pots received a complete fertilizer and one series received also an addn. of 10 g. $CaCO_3$. Without $CaCO_3$ no crop was obtained from the Cd and Fe^{+++} soils, some small yield was obtained from the Mg, Al and H soils. The Sr soil gave just as good a crop as the soil satd. with Ca, which in turn gave just as good a crop as the chernozem. Apparently Sr can replace Ca in the nutrition of plants. The pots which also received $CaCO_3$ gave a crop with all the cations, except Cd. The crops on the Fe^{++} and Fe^{+++} soils were small, and on the Al and Mg soils they comprised 50% of the normal. Thus the Ca cation is one of the most important exchange cations from the standpoint of plant nutrition. From earlier expts. G. cites the effect of a K-satd. soil. Without Ca the K was not available. On H-satd. soils only $CaCO_3$ brought about a normal crop; addns. of $CaSO_4$ had no effect. This is due to the acid reaction produced by the

formation of H_2SO_4. It was also found that part of the Ca may easily be substituted by Mg without any ill effects. J. S. JOFFE

Determination of the percentage base saturation of soils and its value in different soils at definite p_H values. W. H. PIERRE AND G. D. SCARSETH. *Soil Science* 31, 99–114 (1931).—A comparison is made of the base satn. of soils when detd. by the $Ba(OH)_2$–NH_4Cl method and by the $Ba(OAc)_2$–NH_4Cl method. The $Ba(OH)_2$–NH_4Cl method gives appreciably higher total exchange capacities than does $Ba(OAc)_2$. Soils that have been limed show much smaller differences by the 2 methods. Soils of various origins at like p_H values may show considerable differences in percentage satn. In general, highly weathered soils such as those from the Piedmont Plateau and of the Coastal Plains have a lower degree of satn. than do those from the Coastal Plain Black Belt and the Glacial and Loessial Province. There appears to be no relation between org. matter content of soils or the nature of the bases present in the exchange complex and the percentage base satn. at like p_H values. The avidity or strength of acids present varies with different soils. In general, highly weathered soils have weaker acids than the less weathered ones. There is a good correlation between the avidity of soil acids and the percentage of base satn. of soils at p_H 4.80. M. S. ANDERSON

The buffer capacity of soils, methods of determining it and its practical value. P. KUCHINSKII. *Ann. weissruth. staatl. Akad. Landw. Gory-Gorki* 9, 77–104(1929).—K detd. by the method of Jensen the buffer capacity of the loess-like soil in the vicinity of Gorki. The effect of microrelief on the buffer capacity and the variations in the profile were studied. At the same time the exchangeable bases were detd. by the Kappen method as well as by the hydrolytic acidity. The illuviation horizons had the highest buffer capacity; the eluviation horizons, the lowest. When the clay (particles <0.01 mm.) was removed, the buffer capacity was practically zero. The humus portion of the soil is high in buffer capacity. With the increase in buffer capacity the base-exchange capacity is increased. The higher the buffer capacity, the higher the fertility of the soil. On the slopes the buffer capacity is low; in the depressions it is high. There is a correlation between buffer capacity and hydrolytic acidity. J. S. JOFFE

Soil acidity and its practical significance. I. DE V. MALHERBE. *S. African J. Sci.* 27, 253–69(1930) (in S. African Dutch).—The causes and effects of soil acidity are reviewed. Exchange acidity is detd. according to Daikuhara (*C. A.* 9, 500) with methyl red (or phenolphthalein) as indicator (cf. also Goy *et al.*, *C. A.* 24, 5094); the method consists in shaking 100 g. soil with 250 cc. *N* KCl soln. for 1 hr., filtering and titrating with 0.1 *N* NaOH. Comparative results of this acidity with p_H are given for several soils. The hydrolytic acidity (Kapper, Bodenazidität, Berlin 1929) is detd. by titration after shaking with $Ca(AcO)_2$; it is always higher than the exchange acidity. A table for some 150 S. African soils of different natures gives % rock (>0.04 mm.), % clay + humus, p_H and both acidity values. Of the total, 39% is in the neutral class (p_H >5.99) and does not need lime. Thirty-five % is weakly acid (5.50 to 5.99) and needs slight lime addn. if sandy. The exchange acidity is a good indication for this need; it is higher for the humus soil than for the clay soil because of buffer effects. The same holds for the stronger acid soil groups (19% of 5.00 to 5.49 p_H). As a rule lime is always required for soils with more than 2 cc. acidity. Special cases of fertilization are discussed. The type of crop grown is a decisive factor in the matter of liming; the most acid-sensitive crops are corn, barley, sugar beet, cabbage, beans, peas and lucerne. The amt. of lime required for improvement of the soil is discussed and methods for calcn. are given. Many references are included. R. J. C. VAN DER HOEVEN

Active soil acidity and crop yields. I. T. SOLDATOV. *Ann. weissruth. staatl. Akad. Landw. Gory-Gorki* 9, 141–65(1929).—From a series of field expts. in various rotations the relation between the p_H of the soil and its crop response has been established; for rye 5.94 ± 0.014, for oats 6.05 ± 0.090 and for potatoes 5.92 ± 0.13. J. S. JOFFE

The potassium thiocyanate method for determining soil acidity. YUTAKA KAMOSHITA. *J. Imp. Agr. Expt. Sta.* (Japan) 1, 85–8(1930); cf. *C. A.* 16, 136.—Treatment of soil with an alc. soln. of KCNS produces a red color if the soil is more acid than p_H 6.88, and the depth of color is proportional to the acidity of the soil. At the same p_H values, the color increases with exchangeable acidity, since this is accompanied by increase in Al_2O_3 and Fe_2O_3 and decrease in CaO and MgO brought into exchange. The exchangeable Fe^{+++} of soils is therefore considered responsible for a part of the exchange acidity. K. KITSUTA

Change in soil acidity. E. PAASCH. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 309–26(1930).—On limed soils green manuring lowered the p_H about 0.6–1.0. Physiologically acid and alk. reacting fertilizers increase acidity less. Barn manure did not produce increased acidity. H. B. SIMS

Colorimetric determination of p_H values in alkaline soils. P. KAMERMAN. *J. S. African Chem. Inst.* 13, 59–63(1930).—Colorimetric methods for detg. p_H values gave unsatisfactory results. Discrepancies are probably due to hydrolytic effects brought about by the increased water-soil ratio necessitated by the prepn. of a filtered soil ext. B. C. A.

Production of soil carbon dioxide. TH. OEHLER. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 415–21(1930).—Forced ventilation of soil in pots produced larger amts. of CO_2 than was in soils not so treated. Increased CO_2 production resulted in better plant growth. Aeration of soils by tile drainage may result in greater production of CO_2 through the decompn. of soil org. matter and thus increase crop yields. H. B. S.

Temperature variation of cultivated soils. OTTO HEUSER. *Z. Pflanzenernähr. Düngung u. Bodenk.* 9B, 252–67(1930).—Soil temp. at various depths has an important influence on plant growth. The change in soil temp. at the surface, at depths of 5, 17.5 and 30 cm. with respect to air temp. from January to July, is reported. During July the temp. of the surface and 5 cm. depth was slightly higher than the av. air temp. At 17.5 cm. depth the temp. is nearly equal to the av. daily temp., except when rapid changes in air temp. take place. At 30 cm. depth the temp. is a little lower. Variation in daily soil temp. is also caused by rain, liming of soil, cultivation and covering with straw and paper. H. B. SIEMS

Organic compounds associated with base-exchange reactions in soils. W. T. MCGEORGE. Ariz. Agr. Expt. Sta., *Tech. Bull.* 31, 215–51(1931); cf. *C. A.* 25, 161. The arid soils of the Southwest contain only small quantities of org. matter. The compn. and reactions of this org. matter were investigated. *Lignin* and lignin-like substances are the most abundant and active base-exchange agents in arid soils. The exchange capacity of the lignin present in soils is not a const quantity but varies in different soils. The same is true for ligno-humates, although the range of variation is not so great. The aq.-alkali-sol. ligno-humate has a much higher exchange capacity than the alc.-alkali-sol. lignin. Leaching the lignin and ligno humate with H_2O increases the exchange capacity, probably by hydrolysis. The quantity of lignin extd from soils by alc. alkali represents a comparatively small percentage of that actually present. Max. soly. may be obtained by digesting with aq. alkali at increased pressures. Titration of lignic acid (H-satd. lignin) and ligno-humic acid (H-satd. ligno-humate) with KOH and $Ba(OH)_2$ indicates that the lignin mol. is dibasic, and ligno-humate, tetrabasic. The absorption of the base of an acetate by lignin is equal to that required as hydroxide to neutralize the H-satd. salt. Ionization of the acid and basic salts of lignin and ligno-humates was detd. by measuring the cond. of their resp. solns. at several dilns. The Na and K org. complexes show rather high ionization, while those of Ca, Ba and H are very low. The effect of a common ion on ionization and base exchange in org. matter was studied. The influence of a common ion upon replacement by another base is appreciable, but, except for Ca, it is less outstanding than in inorg. zeolites. Xylan exhibits, to a slight degree, the property of base replacement, but this is not of sufficient magnitude to account for the greater exchange capacity of the ligno-humates as compared with lignin. Synthetic humus, prepd. from xylan or cellulose, like that prepd. from sucrose, yielded materials with rather high base-exchange capacities. Xylan, lignin and ligno-humate absorbed color from basic fuchsin soln., and this color was replaceable by the base of a neutral salt soln. Green manure, from ground dry alfalfa, shows an appreciable base-exchange capacity, a large part of which is not easily destroyed by digestion with H_2O_2. The base-exchange capacity of ground alfalfa was increased 4-fold by spontaneous decompn. Just as with soils, the extn. of ground alfalfa with alc. or aq. NaOH yields a lignin of high base-exchange capacity. The lignin content of org. matter and highly org. soils is a linear function of the base-exchange capacity, while there is no relationship between hemicellulose or cellulose and the exchange capacity. The exchange capacity of the org. fraction increases as the org. matter passes through successive stages of decompn. in the soil. A bibliography is appended. C. R. FELLERS

The exchangeable bases in Malmesbury slate soils. M. H. SLABBER. *S. African J. Sci.* 27, 270–9(1930) (in S. Afr. Dutch).—Loam soil samples from the Malmesbury and Stellenbosch districts were studied; they are of slate origin. Top soil (9" deep) and the next layer (18" deep) were used. The Kelley method was used for detn. of exchangeable base (Kelley and Brown, *C. A.* 20, 2382). The results are tabulated for Ca, Mg, K and Na and include p_H. The av. is 5.8 mg. equiv. total exchangeable base for hill soils; it is 3.5 mg. equiv. for lower grounds. These low figures are due more to the colloidal condition of the soils than to an unsatd. condition; the low humus content is significant. The relative ratios of the bases are discussed; in the low grounds Na and

K predominate. Even if more K is available for plant food, the condition of the soils with high univalent-ion content is generally unfavorable; the clay fraction is largely flocculated. The exchangeable-base content of the soils studied is only an av. of 32% of the total base present in them, a figure lower than customary. B. J. C. v. d. H.

Behavior of water in a drained field. Joh. Rothe. *Z. Pflanzenernähr. Düngung u. Bodenk* **9B**, 512–18(1930).—In certain drained soils 26–29% of the total precipitation was found in the drainage water. H. B. Siems

Further studies on the relationship between the concentration of the soil solution and the physicochemical properties of the leaf-tissue fluids of cotton. J. Arthur Harris and Truman A. Pascoe. *J. Agr. Research* **41**, 767–88(1930).—There is in general a pos. correlation between the salinity of the soil and the osmotic concn. as measured in terms of f.-p. depression, sp. elec. cond., Cl content and sulfate content of the leaf-tissue fluids of both Pima Egyptian and Lone Star upland cotton. The correlation between the elec. resistance of the soil and the concn. of all solutes of the leaf-tissue fluids, as measured by f.-p. depression, is higher in both the upland and Egyptian varieties than the correlation between the salinity of the soil and the cond. of the tissue fluids. In general the correlation between the analytically detd. concn. of the 2 ions studied in the soils and the total solutes of the tissue fluids, measured in terms of osmotic concn., is higher than that between these ions and the various measures of electrolyte content of the tissue fluids. In the upland variety the correlations between the soil resistance and total solutes of the tissue fluids are higher than those between soil resistance and the chlorides of the tissue fluids, while the reverse is true with the Egyptian variety. In the Egyptian variety the correlations between soil resistance and total solutes are higher than those between soil resistance and tissue-fluid sulfate content. This is not as marked and may be reversed in the upland type. J. R. Adams

The determination of assimilable nitrogen in soils by the growth of grasses. Reinhold Wagner. *Wiss. Arch. Landw.*, Abt. A, *Pflanze* **5**, 166–200(1930).—The Neubauer method for detg. P and K is extended to the detn. of assimilable N in soils and fertilizers. Westerwold Raygrass was found to give the best index of the N content of the soil, and to utilize the N supplied in any of the common fertilizers. W. Gordon Rose

Soil nitrates as a guide to the nitrogen needs of vegetable crops. H. D. Brown. Ohio Agr. Expt. Sta., *Bimonthly Bull.* **149**, 55–8(Mar.-Apr. 1931).—The nitrate-N spot-plate test of Morgan (*C. A.* **24**, 3072) was used to advantage in testing N deficiencies in soils cropped to various vegetables. For good crop growth the soil should contain 15 or more p. p. m. of nitrates. Fresh strawy manure usually tested 5–7 p. p. m. of nitrates. A concn. of 60 p. p. m. did not injure spinach. N is often not liberated from so-called rich greenhouse soils fast enough for tomato and cucumber production, the crops suffering from N hunger. The remedy is the application of $NaNO_3$. C. R. Fellers

Determination of plant-food content in soils by the citric acid and other methods. J. Hasenbäumer and R. Balks. *Z. Pflanzenernähr. Düngung u. Bodenk* **9B**, 456–73(1930).—The citric acid method for detg. the available P_2O_5 and K_2O of the soil is practically as good as the biological methods. No method is without objections, but chem. detns. have the advantage that they can be carried out quickly. Each method, however, gives an indication in regard to the deficiency, medium content and abundance of phosphate and potash of the soils. H. B. Siems

Permeability of iodine in some economic plants. R. C. Malhotra. *Protoplasma* **12**, 1–22(1931).—Soil was analyzed for I. Portions were then treated with different amts. of that element and used for growing a variety of plants. Carrots take up the most, tomatoes the least. There is no relation between the amt. stored by the plant and the amt. added to the soil. Root crops take up more than leaf crops. The I is localized chiefly in the roots. A soil p_H of 6 is the optimum. Seventy-two references are appended. B. A. Soule

The nutrition of seedlings and the effect on root formation of cereals. Kleeman. *Z. Pflanzenernähr. Düngung u. Bodenk* **9B**, 433–56(1930).—During the germination of seed, enzymes change carbohydrates, fats and proteins into water-sol. components. After enzymic splitting of the large mols., oxidative enzymes then change the fractions into smaller mols. with the loss of CO_2. If the moisture content of the soil is insufficient for germination, enzyme activity may still proceed with the evolution of appreciable amts. of CO_2, thus decreasing the total solids in the seed. Under these conditions the resultant seedling may be greatly weakened. Growth of seedlings may be promoted if the seed is moistened (35–40% H_2O content) from 2 to 3 days in a satd. atm. at 17–18°. To prevent the action of oxidative enzymes, the seed is best stored in a vacuum. The seed is best moistened by a fine spray and not by dipping it in water to prevent the loss

of water-sol. substances. Seed thus treated gives a better root system and a larger crop yield. H. B. SIEMS

Crop rotation. F. MÜNTER. *Z. Pflanzenernähr. Düngung u. Bodenk* **9B**, 529–52 (1930).—The total plant food and the ratio $N:P_2O_5:K_2O$, representing the plant food removed by different field crops, were not const. for the same plant, but depended on weather conditions, tillage, shading, soil conditions and insect injury. Beets removed the most plant food, nearly twice as much as rye and barley. Potatoes and oats followed beets in amt. of removal. Wheat extd. less K_2O. Leguminous plants removed practically as much P_2O_5 and K_2O as potatoes and oats. H. B. SIEMS

A mathematical study of the decrease of crop yields. J. DUDLEY GREAVES. *Soil Science* **31**, 115–22(1931).—Further study of an equation developed for the study of crop yields tends toward the establishment of the 2 assumptions on which the formula was based: The rate of increase of crop yield with increase of the deficient element is proportional to the magnitude of the deficiency of the limiting nutrient from an optimum concn. The time rate of depletion of a deficient element, provided none is added from an outside source, is proportional to the product of the soils content of the deficient element and crop yield. M. S. ANDERSON

Chemical and microbiological study of Lufkin fine sandy loam in relation to productiveness. E. B. REYNOLDS. Texas Agr. Expt. Sta., *Bull.* **421**, 5–30(1931).—In field expts. the nitrifying power of the soil was correlated positively and significantly with the yields of cotton and corn. The nitrifying capacity was a better index of soil productivity than any other method studied. The nitrifying power of the soil was also positively correlated with the total N, total P_2O_5 and available P_2O_5 of the soil. The nitrifying capacity of the soil in the lab. was not affected by the season. Continuous cropping of the soil to corn lowered the nitrifying capacity. The application of nitrogenous materials, cottonseed meal and manure, and also P_2O_5 as superphosphate or rock phosphate, increased both nitrate production and nitrifying capacity. Liming greatly increased nitrate production. C. R. FELLERS

Influence of various non-nitrogenous compounds on the growth of certain bacteria in soils of low productivity. H. J. CONN AND MARY A. DARROW. N. Y. Agr. Expt Sta., *Tech. Bull.* **172**, 3–40(1930).—Two soils of low fertility were sterilized and inoculated with *B. globiforme* Conn and with 2 related species. This organism has N requirements similar to those of green plants, and it was believed that the test might show why the N in these unproductive soils was not available to plants. The bacteria did not grow in the soils unless NH_4 salts, nitrates or other forms of readily available N were added. The addn. to the soils of the hydroxides, sulfates, carbonates or phosphates of the strong alkali metals also made the N of the soil available for the bacteria. It is probable that the cause of the unavailability of the N is adsorption by soil colloids. In this case the bacteria acted like green plants. C. R. FELLERS

The influence of inorganic iodine compounds on the metabolism of some important soil bacteria. HELMUT KARNAHL. *Zentr. Bakt. Parasitenk.*, Abt. II, **82**, 494–518 (1931).—As much as 1 g. per l. of KI, KIO_3, NaI or $NaIO_3$ decreased the production of CO_2. Concns. of I salts below that gave slight increases of CO_2. The respiration rate was slightly decreased, iodate having a greater effect than iodide. I salt concns. between 1 and 10 g. per l. inhibited denitrification. Below that there was little effect. The results for N fixation and urea destruction were similar. JOHN T. MYERS

Presence of Azotobacter and absence of Thiobacillus thioöxidans in peat soils. C. E SKINNER AND I. J. NYGARD. *Ecology* **11**, 558–61(1930).—*Azotobacter* is active in peat soils only at $p_H > 5.9$. *A. chrobcoccum* was found in the more basic soils and *A. Beijerinckii* in those approaching the acid limit. *Thiobacillus thioöxidans* was not found in peat except where S had previously been used as a fertilizer. B. C. A.

The determination of the potassium needs of the soil by Aspergillus niger. H NIKLAS AND H. POSCHENRIEDER, with the collaboration of G. VILSMEIER. *Wiss. Arch Landw.*, Abt. A, *Pflanze* **5**, 152–65(1930); cf. *C. A.* **24**, 5915.—Ten soils of different types were investigated as to their P_2O_5 and K_2O content by the Neubauer method, and by the *Aspergillus niger* method, and the yields of various crops grown on these soils were detd. (1) without fertilization, (2) with fertilizer deficient in (*a*) N, (*b*) H_3PO_4 and (*c*) K, and (3) with complete fertilization. The results obtained from the *Aspergillus niger* method are to be published later with the crop yields reported in this article. W. GORDON ROSE

Potash content of Pfalz soils and conclusions in regard to fertilizer recommendations. M. KLING AND O. ENGELS. *Z. Pflanzenernähr. Düngung u. Bodenk* **9B**, 409–15 (1930).—The root-sol. K_2O in various soils was detd. by the Neubauer method. Tentative "limiting values" of mg. of K_2O per 100 g. dry soil are given as follows: for grain 30,

vegetables and clover 30, grapes 50, tobacco 50, pastures and meadow grasses 30. In many cases the crop yield could be increased by adding potash to the soil, although the soil contained more than the "limiting value" of potash H. B. SIEMS

Nature of the yield curve [of plants] with increasing applications of potash. H. WIESSMANN AND K. NAUMANN. *Landw. Jahrb.* 72, 105–23(1930).—The yield curve of oats and rye grass with increasing supplies of potash approximated to the logarithmic type of Mitscherlich (cf. *C. A.* 24, 2824). Later sowing of the seed caused slight increases in the "effect factor" of potash. The mean values of the "effect factor" of potash with rye grass and with oats were similar, but with the former crop there was a slightly decreased value with the higher applications of potash. In general, values of the "effect factors" for potash were slightly smaller than those of Mitscherlich. B. C. A.

Utilization of increasing amounts of potash on the crop yield of several varieties of barley. H. LIESEGANG. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 397–409(1930).—Four varieties of barley grown in pots varied in their ability to utilize increasing amts. of potash as shown by crop yields, although the amt. absorbed under the same conditions was practically equal. H. B. SIEMS

The effect of sodium nitrate and ammonium sulfate on the availability of soil potash and soil phosphoric acid. M. GRACANIN. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 300–9(1930).—The amt. of phosphate and potash absorbed by plants from the soil as measured by the Neubauer seedling method is increased noticeably when $(NH_4)_2SO_4$ is added to the soil. On extremely acid or alk. soils this effect was not noticeable and in some cases was neg. $NaNO_3$ caused an increase in absorption of P_2O_5 by plants from all soils except one with a p_H 8.35. The increase in the absorption of potash did not parallel the P_2O_5 absorption in all cases H. B. SIEMS

Remarks concerning A. Nemecs treatise "The evaluation of the results of soil analyses with respect to the need of phosphate fertilization." M. v. WRANGELL. *Wiss. Arch. Landw.*, Abt. A, *Pflanze* 4, 635–40(1930) Polemic Cf. N. (*C. A.* 25, 1935) and *Deut. landw. Presse* 57, No. 23(1930) W. GORDON ROSE

The determination of soluble soil phosphates. B. DIRKS AND F. SCHEFFER. *Wiss. Arch. Landw.*, Abt. A, *Pflanze* 4, 641–51(1930). A discussion is given of the methods available for the prepn. of a soln. contg. the easily sol. soil phosphates and of the factors that must be considered in detg. the amt. of phosphate that must be supplied for various crops W. GORDON ROSE

The mechanical analysis of finely divided natural phosphates. LYLE T. ALEXANDER AND K. D. JACOB. U. S. Dept. Agr., *Tech. Bull.* 212, 1–24(1930).—The pipet method for the mech. analysis of soils (*C. A.* 24, 1452) was successfully applied to the analysis of finely divided natural phosphates. For the analysis of phosphates, pretreatment of the sample with H_2O_2 to remove org. matter is omitted The sp. gr. of the original samples and the mech. fractions of the various types of phosphate rock produced in the U. S. do not vary sufficiently to preclude the use of an av. sp. gr. of 3.0 in calcg. the settling velocities of phosphate particles by means of Stokes formula. An exptl. study of the settling velocities of 5-μ phosphate particles at various temps. showed that the rate of fall is considerably slower than the theoretical rate calcd. by means of the customary form of Stokes formula; this is due apparently to the irregular shape of the phosphate particles. The particle-shape factor in Stokes formula as applied to natural phosphates was found to be 0.154. Results obtained by the pipet method, as modified for the analysis of finely divided phosphates, were in excellent agreement with those obtained when 800-g. samples of the phosphates were sepd. into mech. fractions by sedimentation in water regardless of any theoretical considerations, the progress and efficiency of the sepn. being detd. solely by microscopical examn. of the fractions. The possibility of utilizing the pipet method in the mech. analysis of ground limestone and marls is pointed out. W. H. ROSS

Behavior of tricalcium phosphate in cultivated soils. H. DANNEEL AND K. W. FRÖHLICH. *Landw. Jahrb.* 72, 51–8(1930).—$Ca_3(PO_4)_2$ does not dissolve in water in the mol. form. The ratio $CaO:P_2O_5$ in soln. varied from 1:1.1 at dilns. of 1 in 200 to 1:2.6 at dilns. of 1 in 50,000. The bearing of this on the compn. and soly. of naturally occurring phosphates is discussed. B. C. A.

Technical problems of the superphosphate industry. BRUNO WAESER. *Metallbörse* 21, 75–6, 123–4, 173–4(1931).—If crude phosphate meal is stirred with sufficient dil. H_2SO_4 to form $CaHPO_4$ and convert $CaCO_3$, Fe_2O_3 and Al_2O_3 into sulfates, a part of the impurities is sepd. in the acid filtrate and the residue contains $CaHPO_4$, $CaSO_4$ and undecompd. CaF_2 and silicic acid. $CaHPO_4$ is then changed to $CaH_4(PO_4)_2$ with more H_2SO_4. The prepn. of H_2O-free $CaH_4(PO_4)_2$ is technically possible by the treat-

ment of $CaHPO_4$ with 100% H_3PO_4 in a ball mill. A mixed fertilizer can also be obtained by the reaction $Ca_3(PO_4)_2 + 4HNO_3 = CaH_4(PO_4)_2 + 2Ca(NO_3)_2$. J. R. H.

Effect of fertilizers on phosphoric acid and calcium absorption of various plants. D. MEYER AND P. OBST. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 488–512(1930).—In pot expts. with oats and tobacco, it was found that different forms of inorg. N compds. showed little difference in crop yields. Addn. of lime increased the yields in some cases and in others decreased them slightly. Results indicate that various N fertilizers may increase or decrease P_2O_5 and CaO absorption, the effect depending on the kind of plant and N compd. used. The addn. of $CaCO_3$ to the soil increased the CaO absorption, but the increase depended on the particular plant and N compd. used. Lime and various N fertilizers gave varying results in regard to P_2O_5 and CaO absorption from fertilization with di- and tri-calcium phosphate and no added phosphate. H. B. SIEMS

A field method for determining phosphoric acid in phosphate rock. E. N. ISAKOV AND V. A. KAZARINEVA. *Udobrenie i Urozhai* (*Fertilizers and Crops*) 2, 416–20(1930).—The phosphate rock is ground to pass a 0.5 mm. sieve; 15–20 g. is placed in a weighing dish and dried for 3.5 hrs. at 105°. A 4 g. sample is dissolved in 40 cc. aqua regia by heating for 30 min. It is then made up to a vol. of 250 cc. and further diluted to a dilution of 0.0001. The Denigés method is then used, making up a series of standards in tubes and comparing the unknowns with them in the same way as with p_H detns.—colorimetric method. It was found to be accurate with a max. error not exceeding 2%. J. S. JOFFE

Note on phosphoric acid of barley grain. E. M. CROWTHER. *J. Inst. Brewing* 36, 349–51(1930).—The P_2O_5 contents of various types of barley differed from each other, but no general relationship was found which could be assocd. with the type of fertilizer used in growing the barley or with any other characteristic of the barley. PETER J. F. WERER

Fertilizing experiments with phosphorite. G. TOMMASI AND S. DOJMI DI DELUPIS *Publ. Real staz. sper. chim.-agr. Roma* No. 271(1930); *Chim. ind. agr. e biol.* 7, 33–4(1931).—The Kosseir (Egypt) phosphorite contains moisture 2.85, combined H_2O 0.20, org. matter 0.58, CO_2 6.40, total P_2O_5 29.5, P_2O_5 sol. in 2% citric acid 5.75, SO_3 0.95, Cl 0.25, F 1.40, Fe_2O_3 1.05, Al_2O_3 1.54, CaO 45.50, MgO 1.95, Na_2O 0.52, K_2O 0.10, SiO_2 and sol. silicates 6.50%. Field plot and lab.-fertilizing expts. were made with this material on different soils (the complete mech. and chem. analyses of which are given) and with wheat, lucerne, beans, etc. With neutral soils or soils near neutrality, the results were not very good, but with lucerne on lime-free soils they were excellent. Phosphorite is efficient in grains <0.05 mm.; the results are better if it is mixed with ordinary superphosphates. G. A. BRAVO

"Nitrophoska." W. WERNER. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 339–60(1930).—On heavily limed and very sandy soils with low absorption capacity, "Nitrophoska" may produce $(NH_4)_2CO_3$, which may cause loss of N and plant injury on account of free NH_3. On av. agricultural soils this is not so noticeable except in special cases. The P_2O_5 in "Nitrophoska" present as $(NH_4)_2HPO_4$ is equiv. to superphosphate in regard to crop yields. For sandy soils, the P_2O_5 in superphosphate is superior. In heavier soils, P_2O_5 from "Nitrophoska" is occasionally superior. Physiologically, its reaction is neutral to feebly acid. H. B. SIEMS

Field trials with "Nitrophoska." F. HONCAMP AND H. WIESSMANN. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 361–3(1930).—The 3 grades of "Nitrophoska" alone or supplemented with N as "Leunasalpeter" ($(NH_4)_2SO_4.NH_4NO_3$), K as KCl and P_2O_5 as superphosphate gave good results on potatoes, turnips and oats. The crop yields were as high or slightly higher than in cases where the N, P and K had been used separately on the same field. H. B. SIEMS

Measuring absorbed phosphates and nitrogen. W. J. SPILLMAN. *Science* 73, 215–6(1931).—Small quantities of phosphate and nitrate fertilizers are absorbed by the soil. An excess of fertilizer over that necessary to satisfy this absorptive power of the soil must be added before the growing crops will obtain any beneficial effects from the fertilizer. The quantity of fertilizer made unavailable by absorption is found by detg. the point on the crop-yield curve which corresponds to the observed yield when no fertilizer is added. J. R. ADAMS

Pasture fertilization with nitrogen. MÖLLER. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 363–77(1930); cf. *C. A.* 24, 5099.—A basic application of 60 kg. P_2O_5 and 100 kg. K_2O per hectar was made. Two, and in some cases three, applications of N were made at a total rate of 40, 80 and 120 kg. N per hectar. High N applications were profitable. H. B. SIEMS

"Humunit." K. ECKL. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 378–82

(1930).—A humus-contg. product sold under the trade name "Humunit" was found practically valueless from the standpoint of crop production. H. B. SIEMS

The solubility of water-insoluble phosphates in silicic acid. W. OBST. *Centr. Zuckerind.* **39**, 67(1931).—A discussion of the effect of Thomas' slag meal (fertilizer). J. F. LEETE

Decomposition of organic fertilizers. II. Relations between the chemical composition and decomposition. SIGERU OHSUGI AND SHUSHI YOSHIE. *J. Agr. Chem. Soc. Japan.* **6**, 917–26(1930).—Soy-bean oil cake, rape-seed oil cake, *Astragalus sinicus*, Saatwicken, rice straw, herring cake and bone fertilizer were analyzed. Seventy-five g. of these org. substances mixed with 1.5 kg. soil were kept in the pots (the area is 1/50000 *tan*) under the condition that max. moisture content is 50% and temp. 25°. The decompn. velocity was rapid during the first 17 days. The ether ext. is easily decomposed. The decompn. of an aq. ext., especially of reducing sugars and org. N compds., is generally easy. Water-sol. ash of animal origin becomes insol. with greater difficulty than does that of plant origin. The decompns. of cellulose and hemicellulose are, resp., 70–80% and 60–70% in the presence of abundant N. The decompn. of org. N is under 60%. This may be due to absorption by microorganisms. The decompn. of lignin is difficult. Y. KIHARA

Effect of barn manure on soil conditions. S. GOY. *Z. Pflanzenernähr. Düngung u. Bodenk* **9B**, 481–7(1930).—Soils to which barn manure was applied showed, after a year, a slight increase in hydrolytic soil acidity. Manured plots usually showed, after removal of the crop, more residual root-sol. P_2O_5 and K_2O than did the check plots as shown by the Neubauer seedling method. Although the manure added more N than the plants absorbed, there was a definite loss of N as shown by König's method. H. B. SIEMS

The influence of drying manure on the nitrogen losses and on crop yields. I. P. MAMCHENKOV AND I. F. ROMASHKEVICH. *Udobrenie i Urozhai* (*Fertilizers and Crops*) 2, 394–7(1930).—Manure was taken to the field and either plowed under immediately or after 1, 2 and 5 days. The manure which was not to be plowed under immediately was placed in the field either in piles or scattered. It was found that the manure became almost air-dry. Analyses showed that the manure in the piles lost more N than the scattered manure. In the scattered manure the losses consisted primarily of NH_3, which escapes during the first 2 days. Expts. with oats have shown that the manure which was allowed to dry out in the field was slightly inferior. In pot expts. both fresh and dried manure gave the same results. When lime was added to the manures the dry manure was not so effective. J. S. JOFFE

A comparison of the various methods of storing manure. I. P. MAMCHENKOV. *Udobrenie i Urozhai* (*Fertilizers and Crops*) 2, 284–91(1930).—Three methods were tried. (1) loose throwing together of manure, (2) compacting, (3) the Krantz method (cf. *C. A.* **21**, 3493). In all cases the manure was cow manure with the addn. of 12% fresh horse manure. The various batches were kept in specially prepd. pits. In the 1st case the manure was piled up loosely 1.25 m. deep and kept that way. For the Krantz method the manure was piled up to 1 m., allowed to heat up to 55° and then compacted. After that another layer 1 m. deep was placed and again allowed to heat up to 55° and compacted. Two series were run: one with straw, the other with peat-moss as bedding. Detns. were made for NH_3 N on a water ext.; then the manure was treated with MgO to det. the combined N. Besides that, a sep. sample was treated with 0.05 *N* HCl and the ext. distd. over for total NH_3. In the fresh manure there was found, on the basis of 100 parts of abs. dry wt., 2.7% total N, of which 1.773% was protein N, 0.818% NH_3 N and the rest other forms. This was for the manure with straw. For the manure with peat the following was found: total N 3.3, protein N 1.877 and NH_3 N 1.248%. After 4 months the pits were opened and analyses made on the manure batches. The loosely packed manure lost 27.3% dry matter with the straw and 23.0% with the peat; the compacted, 9.9% and 3.4%; the Krantz manure, 21.0% and 10.2%. The N losses were: with method (1) 36.7% with the straw and 34.66% with the peat; method (2) 12.59% and 25.94%; method (3) 26.3% and 19.0%. The distribution of the forms of N in the manure kept by the 3 methods was: in (1) total N 2.35 with the straw and 2.8 with the peat, protein N 1.752 and 2.296, free NH_3 and $(NH_4)_2CO_3$ N 0.346 and 0.152, combined NH_3 N 0.152 and 0.164, NO_3 N 0.0016 and 0.009; in (2) total N 2.62 and 2.53, protein N 1.698 and 1.222, free NH_3 and $(NH_4)_2CO_3$ N 0.308 and 0.436, NO_3 N 0.0016 and 0.0022; in (3) total N 2.520 and 2.97, protein N 1.587 and 1.824, free NH_3 and $(NH_4)_2CO_3$ N 0.415 and 0.829, combined NH_3 N 0.434 and 0.208, NO_3 N 0.0018 and 0.0018. Thus in the loosely packed and Krantz manure there is a transformation of mineral N into protein N, but there is a greater loss of N. Pot expts. (5 kg.

of soil per pot) were conducted with the variously stored manures on oats. $NaNO_3$ was used as the check pot. All received similar amts. of P and K. It was found that $NaNO_3$ gave better results than did the manures. The mineral N from the manure is immediately available, whereas the protein N is not. It is concluded that the system of packing down the manure is the best one, since it preserves the mineral forms of N.
J. S. JOFFE

The use of excess molasses. H. CLAASSEN. *Deut. Zuckerind.* 55, 1377–8(1930).—The author discusses the use of beet molasses as *fertilizer* and recommends further experimentation. J. F. LEETE

Floating factories. H. HAUPTVOGEL. *Chem.-Ztg.* 53, 786–7, 806–7(1929).—A detailed, illustrated description is given of vessels equipped to catch and prep. fish and produce *fertilizer* from the waste. The modern, floating *whale oil* plants are described briefly. E. M. SYMMES

Organic fertilizers for oats and flax. Z. V. LOGVINOVA AND A. P. SHCHERBAKOV. *Udobrenie i Urozhai* (*Fertilizers and Crops*) 2, 476–82(1930).—N sources from meat scrap, horn meal, horn shavings, burned horn meal, blood meal, slime from intestines, feathers and down, oil meal, tobacco dust and wool combings were compared in pot expts. with $NaNO_3$ and $(NH_4)_2SO_4$ on oats and flax. Two sets of pots with 4.5 kg. of soil were set up. One set received 0.5 g. N, the other, 1.0 g. All pots received P in the form of Na_2HPO_4 and K in the form of K_2SO_4. The results with the oats were: the slime gave almost as good results as the mineral forms of N. The meat scrap, horn meal, horn shavings, burned horn, blood meal, feathers and down and oil meal fell behind the mineral N when 0.5 g. of N was added. With the double quantity of N these materials were just as efficient as the mineral N. The dried blood, tobacco dust and wool combings were far behind the mineral N even when 1.0 g. of N was added. The residual effects of the various org. forms of N on the succeeding crop were far superior to those of the mineral N. With flax the 0.5 g. of org. N was just as good as the mineral N; with the 1.0 g. quantity the org. N was superior to the mineral forms of N. The second crop on the flax pots was oats, and since the flax did not utilize the mineral N, it was effective on the oats giving higher yields than the residual org. N. The quality of the flax was also better with the org. forms of N. J. S. JOFFE

Fertilizing tomatoes, sweet potatoes and muskmelons in a three-year rotation. J. W. LLOYD. Ill. Agr. Expt. Sta., *Bull.* 364, 18 pp.(1931).—Field expts. continued for 6 years showed that P is especially important in the production of tomatoes. The most efficient form of P was steamed bone meal. K decreased the yield of melons and was of little or no benefit to tomatoes or sweet corn. Com. N in the form of $NaNO_3$ or dried blood increased the yield of tomatoes but decreased the yields of melons and corn. $(NH_4)_2SO_4$ decreased the yields of all crops. Dried poultry manure increased the yields of tomatoes and corn. Limestone, when used with manure, increased the yields of tomatoes, sweet corn and melons, 7, 14 and 25%, resp., as compared with the use of manure alone. For a 3-year rotation of melons, tomatoes and corn, limestone and manure should be added the first year, steamed bone and dried blood the second year, and no fertilizer is required for the third year. C. R. FELLERS

Fertilizing of mildewed vines. HENRI ASTRUC. *Prog. agr. vit.* 94, 499–502(1930).—A. recommends treating vine maladies brought on by a wet season by judicious fertilizing. He favors mixts. of org. and chem. fertilizers rather than only the easily sol. chem. fertilizers which are rapidly removed from the root zones. Such mixts. should furnish nourishment during the entire vegetating season. A N excess should be avoided, as this overstimulates foliage production and thus encourages mildew growth.
F. W. MARSH

Use of manganese in vegetable greenhouses. I. C. HOFFMAN. Ohio Agr. Expt. Sta., *Bimonthly Bull.* 149, 58–62(Mar.-Apr., 1931).—See *C. A.* 24, 5102.
C. R. FELLERS

Results obtained by two winter sprayings and one spring spraying on the vegetation of trees and the quality of fruits. L. CHASSET. *Prog. agr. vit.* 94, 502–5(1930).—These 3 treatments produced the best results. The first winter spraying was with a mixt. of anthracene oil, formol and schist oil, followed a few days later by lime-sulfur. In the spring a Cu arsenical spray was used. F. W. MARSH

Solubility of Bordeaux. GEO. L. HOCKENYOS. *Phytopathology* 21, 231–4(1931).—The colorimetric method of Callan and Henderson (cf. *C. A.* 24, 312) for detecting Cu, which is sensitive to 1 part in 25,000,000, is applied to the detn. of the percentage of Cu in a series of Bordeaux mixts. contg. various ratios of Cu to hydrated lime. When the Cu:Ca ratio was 1:0.169, 0.04% Cu was present in soln.; with a ratio of 1:0.27 it fell to 0.00009%; with a ratio of 1:0.67 the sol. Cu was found to be 0.00013%, and it remained

at this level when the ratio was made 1:1 or 1:2. The detn. is made by adding to 17.5 cc. of the soln. to be tested 0.5 cc. NH_4OH and 2 cc. 1% Na diethylthiocarbonate and comparing in a Duboscq colorimeter with 2 cc. 0.0002 *N* $CuSO_4$ soln. diluted to 17.5 cc. and similarly treated. JOSEPH S. CALDWELL

Factors influencing the character of Bordeaux mixture. W. NEWTON, F. B. JOHNSTON AND C. YARWOOD. *Proc. Can. Phytopath. Soc.* 1929, 21–6(1930); *Rev. Applied Mycol.* 10, 118.—The ideal spray is probably obtained when the solids are in a state of max. dispersion. Best results and slowest settling is obtained when the reacting solns. are as cold as possible, when the $CuSO_4$ soln. is poured slowly into the lime suspension rather than conversely and when the $CuSO_4$ is as dil. and the lime suspension as concd. as practicable. Addn. of Na silicate, fresh skim milk, various alcs., wheat flour, whale oil soap, various washing soaps, agar, alkali, or sodium resin soap failed to improve the Bordeaux mixt., while 0.15 to 0.5% Ca caseinate, 0.5% gelatin, Crystal White brand soap, or potassium resin soap did improve the Bordeaux somewhat. ODEN E. SHEPPARD

Analysis of commercial lime-sulfur materials. TETSUNOSUKE ONOUE. *J. Imp. Agr. Expt. Sta.* (Japan) 1, 89–90(1929).—High. sp. gr. of lime-sulfur soln. does not always indicate high sulfide-S content. The quality should be detd. by detn. of active-S content and not by sp. gr. K. KITSUTA

Determination of barium fluosilicate spray residue. R. H. CARTER. *Ind. Eng. Chem., Anal. Ed.* 3, 146–7(1931).—The apples are washed by immersion for 30 sec. in a boiling 3% NaOH soln. and rinsed with slightly acidulated H_2O. The rinsings and washing soln. are cooled, made strongly acid with HCl and rapidly filtered. The filtrate is then made strongly alk. with NaOH, and the Ba is pptd. as $BaSO_4$ with an excess of H_2SO_4. The $BaSO_4$ is then calcd. to Ba fluosilicate. This method is fairly rapid and gives reproducible results which are sufficiently accurate for comparative work. J. R. ADAMS

Tests of treatments against the apple worm. PEYRIÈRE. *Prog. agr. vit.* 95, 81–3 (1931).—The treatment of apple trees with Cu-arsenical sprays 3 times during the progress of flower formation proved effective. F. W. MARSH

The fungicidal action of ultra-violet radiation. W. A. R. DILLON WESTON AND E. T. HALNAN. *Phytopathology* 20, 959–65(1930).—The work in part parallels that of Fulton (cf. *C. A.* 24, 1926). Cultures on potato agar were irradiated for varying periods with a quartz Hg-vapor (Alpine sun) lamp through covers of Vita or Sanalux glass. The effect was to inhibit the growth of the mycelium, and when radiation ceased, growth was renewed at a rate proportional to the time and distance of the previous radiation. Under weaker dosage, growth of the mycelium at the surface ceased but persisted deep in the medium. Concordant results were obtained with 12–14 species. J. S. C.

Physical and chemical action of ultra-violet rays on sublimed sulfur. FONZES-DIACON. *Prog. Agr. vit.* 95, 155–8(1931).—Expts. showed that ultra-violet rays did not effect the retrogradation of sublimed S. The reason for the action of S on oidium is discussed. F. W. MARSH

The relation of pentathionic acid and its constituents to the toxicity of sulfur fungicides. O. NEAL LIMING. *Phytopathology* 21, 131–2(1931).—At summer temps. over 10% of the S on a dusted surface may pass off within 2 weeks. S vapor is not toxic to fungus spores. H_2S is present only in traces and is non-toxic in those concns. Pentathionic acid is present in concns. toxic to fungus spores, and its formation is enhanced by mild oxidizing agents and possibly by H_2S. It is stable in both acid and weak alk. solns., but toxic only in the former. It is not sufficiently volatile in dil. solns. to be toxic at a distance. The toxic action is governed by the condition of the fungus rather than by that of the pentathionate ion. JOSEPH S. CALDWELL

Sulfuring apricots. GEO. QUINN, C. G. SAVAGE, A. V. LYON AND W. R. JEWELL. *J. Dept. Agr. S. Australia* 34, 513–4(1931).—The authors, serving as a comm., recommend in detail a procedure for sulfuring fruits. M. S. ANDERSON

Fumigating tomato houses with hydrocyanic acid gas to destroy white fly (Trialeurodes vaporarium). GEO. QUINN. *J. Dept. Agr. S. Australia* 34, 519–20(1931).—A detailed procedure is given for the use of HCN as a fumigant. M. S. ANDERSON

Mercury in the disinfection of seeds. VITTORIO CASUBURI. *Industria chimica* 5, 1474–82(1930); cf. *C. A.* 25, 1942.—The various Hg compds. previously studied are compared, and the conclusion is that *Dry Tan* is the most efficient, both as an insecticide and in the promotion of germination. A. W. CONTIERI

Disinfection experiments on cotton seeds with the dusts Tillantin R and ceresan. F. FORSTENEICHNER. *Nachr. über Schädlingsbekämpf* 5, 136–47(1930); *Rev. Applied*

Mycol. 10, 103.—Excellent control of a species of *Rhizoctonia* and the facultative parasites accompanying it was obtained by use of Tillantin R and ceresan at the rate of 1 kg. per 100 kg. seed. Ceresan is most effective. The cotton seedlings are infected commonly by this species in the Adana region of Turkey. ODEN E. SHEPPARD

Contribution to the problem of cereal rust control by chemical methods. G. GASSNER AND W. STRAIB. *Phytopath. Z.* 2, 361–76(1930); *Rev. Applied Mycol.* 10, 88–9.—S with and without an equal admixt. of kaolin, 1% Bordeaux, 1% Cu chloride, Ca cyanamide mixed with kaolin, basic slag and calcined lime dusts and kainite were used in the control of brown and yellow rust (*Puccinia triticina* and *P. glumarum*) on Heine's Kolben and Dickkopf wheat and of *P. dispersa* (*P. secalina*) on Petkus winter rye Ca cyanamide mixed with large quantities (up to 99%) of kaolin gave very excellent protection, and G. and S. consider its use on a large scale. S and Bordeaux gave very good control, but the others gave little control, while Cu chloride caused much leaf burning, and $NaNO_3$ actually increased the rusts. ODEN E. SHEPPARD

The treatment of the rot of wheat (1929–1930). G. ARNAUD AND MISS GAUDINEAU. *Compt. rend. acad. agr. France* 16, 1029–35(1930); cf. *C. A.* 24, 4577.—Among the anti cryptogamic chemicals a 5% $CuSO_4$ soln. is very satisfactory. The use of the $CuSO_4$ soln. is followed by a dusting of the grains with CaO which in turn is followed by a thorough washing with H_2O. The Bordeaux mixt.-casein prepn. has given some excellent results, and in many cases treatment with formol has been very efficacious. J. R. ADAMS

Effect of some factors influencing disease conditions of potatoes. H. REILING. *Z. Pflanzenernähr. Düngung u. Bodenk* 9B, 393–7(1930).—Potato scab occcurs principally on alk. soils. Acid soils usually produce potatoes free from scab, but tubers and the plant itself may become infected with *Rhizoctonia solani*, particularly during drought Lack of potash in the soil may produce brown rings in the tuber and on the surface. H. B. SIEMS

The leaf diagnosis of the potato. I. HENRI LAGATU AND LOUIS MAUME. *Ann. sci. agron.* 47, 595–653(1930).—The chem. state of a leaf taken from a conveniently located place at a particular moment is called "the leaf diagnosis at a given instant." "The annual leaf diagnosis" is the series of chem. states of the leaf revealed by the analyses at different periods during the entire growing cycle. The results of this method are compared with indications furnished by the yields and by observations on developments. The percentages of potash, N, acid phosphate and lime detn. by the leaf diagnosis method on samples harvested on 5 dates in May and June from plots differently fertilized showed clear variations. Plots similarly fertilized gave concordant results. A definite relation is established between the leaf-diagnosis results and the fertilizers used. In general, N and acid phosphate in the leaf decreased with plant age, while lime increased. Comparisons of diagrams for N and potash show a rise of the N curve, or a lowering of that for potash or the two displacements together. Conclusion: N was needed for potatoes, but not acid phosphate or potash. In another expt. an excess of N in certain complete fertilizers was observed. Results of the study of the effect of the conditions of the cultivation media on the plant and on the leaf composition are considered. F. W. MARSH

Effect of seed-potato treatment on yield and rhizoctonosis in Florida from 1924 to 1929. L. O. GRATZ. Fla. Agr. Expt. Sta., *Bull.* 220, 5–30(1930).—Numerous field expts. conducted over a period of 6 years show no yield increases and pos. indications of definite injury from the use of *org. Hg compds.* for seed-potato treatment. The use of $HgCl_2$, hot CH_2O or org. mercurials is not justified under Fla. conditions. Ninety two references are appended. C. R. FELLERS

Increased yields from spraying and dusting late potatoes. J. E. HOWITT. *Proc. Can. Phytopath. Soc.* 1929, 19–20(1930); *Rev. Applied Mycol.* 10, 125–6.—In 1928 potato plots treated with liquid Bordeaux (4–8–40) yielded 291 bushels per acre, plots dusted with copper-lime yielded 255.5 bushels and control plots 194.5 bushels, while in 1929 the corresponding figures were 235, 193 and 156. In 1928 the beneficial effect was probably due to the preventive action of the fungicides on late blight and rot, and in 1929 the beneficial effect was correlated with tip burn. ODEN E. SHEPPARD

The control of oidium leaf disease. R. K. S. MURRAY. *Trop. Agr.* (Ceylon) 75, 294–302(1930).—S dusting is a quick and effective means of controlling oidium leaf disease. JOHN O. HARDESTY

Observations concerning the development and struggle against mildew in 1930 in the Isere. L. ROUGIER. *Prog. agr. vit.* 94, 566–9(1930).—Cu was found to be the best remedy for use against this parasite. F. W. MARSH

Copper and mildew. JAQUES LUGAN. *Prog. agr. vit.* 94, 462–3(1930).—L. dis-

agrees with Villedieu (*C. A.* **25**, 372) in certain conclusions concerning the use of ammoniacal fertilizers for grapevines and of Cu as a mildew combatant. F. W. MARSH

The effect of boron on powdery mildew and spot blotch of barley. FRANK M. EATON. *Phytopathology* **20**, 967–72(1930).—Barley was grown in pans of quartz sand, so arranged as to be flushed daily with nutrient solns. In crops grown during the summer, the plants receiving no B were heavily infested with mildew but were free of spot blotch; those receiving 5–25 p. p. m. of B were free of mildew but showed heavy infestation with spot blotch. In winter plantings, mildew was present in all the beds, most abundantly in those receiving no B, and decreased in amt. with increase in B applied. Spot blotch did not appear in the B-free bed but was abundant in all those receiving B. On wheat, powdery mildew was present irrespective of the amt. of B supplied. The B content of the summer-grown plants ranged from 57 p. p. m. dry weight on the B-free cultures to 1349 p. p. m. in those receiving 25 p. p. m. of B in the culture soln.
JOSEPH S. CALDWELL

Lessening of growth of rice plants. MIRANDA LANZA. *Boll. lab. sper. fitopatol.* (Torino) **8**, No. 1, 6–9(1931).—The observed disease is due to fungous parasites which winter on the seeds. They may be destroyed by immersion for 24 hrs. in 0.2% Kalimat (a mixt. of formaldehyde and phenol). G. A. BRAVO

Sugar beet root-rot control. H. C. YOUNG. Ohio Agr. Expt. Sta., *Bimonthly Bull.* **148**, 15–8(Jan.-Feb., 1931).—Field expts. showed that the application of 500 lb. of NaCl per acre often materially increased the stand of beets, and no injury to the crop was recorded on any plot. C. R. FELLERS

Use of oxides of unsaturated hydrocarbons for the eradication of barberries and other pests. R. B. HARVEY. *Phytopathology* **21**, 126(1931).—Ethylene oxide and propylene oxide have been used for killing gooseberries or barberries. A depth charge is injected beneath the plant by means of a prod rod or "gopher stick" provided with a measuring chamber and connected directly with the gas tank, or a soln. of ethylene oxide in water can be injected from a knapsack sprayer. The stems blacken and the leaves fall off, the plants dying in 1–2 weeks. JOSEPH S. CALDWELL

Pyrethrum (ZOCHARKEWICZ) **17**. Fodder and quality of milk in meadow fertilization with $CaCN_2$ (HERMANN) **12**. A brief history of the world's phosphate rock production (GRAY) **18**. Tung-oil tree (NEWELL, *et al.*) **26**. Mineralogical study of the soil of the Vercelli district (REPOSSI) **8**. Lignin, humic acid and humin (FUCHS) **10**. Handbuch der Pflanzenernährung und Düngerlehre. Edited by FRANZ HONCAMP. **Band II. Düngemittel und Düngung.** Contributions by Ernst Hugo Birei, Hand Brenck, R. Demoll, *et al.* Berlin: J. Springer. 919 pp. M. 86; linen, M. 89.80.

Fertilizer. OTTO RIPKE (to I. G. Farbenind. A.-G.). U. S. 1,793,133, Feb. 17. NH_4CNS is heated (suitably at a temp. of about 300°) until evolution of gases has ceased.

Fertilizers. A. HOLZ and T. VAN D. BERDELL. Brit. 337,402, July 30, 1929. Tri-Ca phosphate is decompd. with mixed H_2SO_4 and HCl, and the insol. $CaSO_4$ is sepd. from the sol. H_3PO_4 and $CaCl_2$. The $CaSO_4$ is treated with a K compd. such as KOH in the presence of CO_2 (preferably under pressure and heat) or K_2CO_3 to form K_2SO_4 and $CaCO_3$. The $CaCO_3$ is sepd. and is added to the soln. contg. H_3PO_4 and $CaCl_2$ in the presence of $Ca(OH)_2$ to ppt. di-Ca phosphate, which is then sepd. and mixed with the K_2SO_4 soln., and the mixt. is spray-desiccated to produce a granular product. Various auxiliary procedures are described.

Fertilizer. A. HOLZ and T. VAN D. BERDELL. Brit. 337,415, July 30, 1929. A mixed fertilizer free from chlorides is prepd. by treating KCl with H_2SO_4 to form $KHSO_4$ and HCl gas, expelling the HCl (preferably at a temp. well below 200°) and then treating the $KHSO_4$ with NH_3 to form K and NH_4 sulfates. The HCl is passed into an aq. suspension of rock phosphate to form $CaCl_2$ and H_3PO_4, insol. solids are sepd. and sufficient $Ca(OH)_2$ is added to ppt. di-Ca phosphate, which is then sepd. and dried (preferably at a temp. not much above 100°) and mixed with the K and NH_4 sulfates. Various details and slight modifications of procedure are described.

Fertilizers. I. G. FARBENIND. A.-G. (Ernst Jänecke, inventor). Ger. 514,509, Nov. 20, 1929. Nitrogenous fertilizers are prepd. by leading gases contg. N_2O_3 into a soln. of NH_4 salt in concd. H_2SO_4 and HNO_3, and working the product up into a nitrate- and sulfate-contg. product. In the example, N_2O_3 is led into a soln. of $(NH_4)_2SO_4$ in 50% HNO_3 to give the fertilizer $(NH_4)_2SO_4.NO_3$.

Fertilizers. N. V. MAATSCHAPPIJ TOT EXPLOITATIE VAN VEREDELINGSPROCÉDÉS. (Paul Erasmus, inventor). Ger. 514,510, Nov. 7, 1928. Carbohydrates of vegetable origin such as peat, lignite, sugar, cellulose, wood, etc., are heated to about 300° with NH_3 under pressure to form a nitrogenous fertilizer. Examples are given.

Fertilizers. KUNSTDÜNGER-PATENT-VERWERTUNGS A.-G. Swiss 141,328, Oct. 16, 1928. See Brit. 310,276 (*C. A.* 24, 679).

Fertilizers. SOCIÉTÉ D'ÉTUDES CHIMIQUES POUR L'INDUSTRIE. Swiss 140,729, Nov. 20, 1929. A nitrogenous fertilizer contg. $CaCN_2$ is produced by the action of NH_3 on $CaCO_3$ in a current of mixed H and N at 500–1000°. Cf. *C. A.* 25, 767.

Fertilizer and sodium bicarbonate. SOC. CHIMIQUE DE LA GRANDE-PAROISSE AZOTE ET PRODUITS CHIMIQUE. Brit. 338,007, Jan. 11, 1929. The process for producing a composite fertilizer and $NaHCO_3$ by double decompn. of $NaNO_3$ and KCl and treatment of the mixt. produced with NH_3, CO_2 and water, as described in Brit. 331,451 (*C. A.* 25, 165), is modified by effecting the double decompn. reaction of $NaNO_3$ with the KCl in the mother liquors of the process, as by introducing these materials into the soln. at that point of the manuf. at which the pptn. and sepn. of $NaHCO_3$ have been effected.

Rendering insoluble phosphates available for fertilizer. HANS LEHRECKE. U. S. 1,795,173, March 3. Material such as mineral phosphate is heated to about 1000–1400° with such quantities of C and silica-contg. addns. that part of the total P content of the initial material is liberated in accord with the equation: $P_2O_5 + 5C = P_2 + 5CO$ and that in the calcined residue contg. the remaining P there is a proportion of P_2O_5 about 0.9–1.1, SiO_2 about 0.9–1.1 and CaO about 4.8–5.2 mols.

Treating phosphate rock. KUNSTDÜNGER-PATENT-VERWERTUNGS-A.-G. Brit. 338,079, March 7, 1929. In leaching phosphate rock with HNO_3 and K_2SO_4, a part of the soln. of H_3PO_4 and KNO_3 from a previous operation (partly freed from KNO_3 by cooling and crystn.) is used as a diluent, thus preventing the pptn. of $CaSO_4$ contg. a high percentage of K. Various details of treatment for prepg. *fertilizer* are described, which may include addn. of NH_3.

Superphosphates. FRANCESCO C. PALAZZO and FORTUNATO PALAZZO. Swiss 141,561, Nov. 3, 1928. Superphosphates with 42–51% of P_2O_5 capable of assimilation are obtained by repeatedly extg. a superphosphate contg. 14–17% P_2O_5 capable of assimilation with half its weight of water, pptg. the H_3PO_4 by milk of lime and adding the $CaHPO_4$ to other exts. contg. free H_3PO_4. Cf. *C. A.* 24, 680.

Superphosphates. FRANCESCO C. PALAZZO. Swiss 142,459, Sept. 27, 1928. Phosphates with a content of 42–45% assimilable P_2O_5 are prepd. by kneading concd. H_3PO_4 (*e. g.*, obtained by working up phosphorites) with pure pptd. $CaHPO_4$ at 40–50° for about 2 hrs. The mixt. is vacuum dried and powd.

Superphosphate chambers. D. WELLISCH. Brit. 338,075, Jan. 31, 1930. Various different constructions are described, designed so that the reaction mass and its support are moved in relation to that part of the chamber which contains the charging device. One form comprises a cylindrical chamber mounted for rotation around a vertical axis and which, after initial charging, is adapted for continuous operation. Knives or compressed air may be used to break up the mass.

Apparatus for leaching out raw materials. KUNSTDÜNGER-PATENT-VERWERTUNGS A.-G. Swiss 141,300, Oct. 16, 1928. Raw material is placed in a succession of tanks of which each is lower than the preceding one, and the acid solvent from the bottom of one tank is led to the top of the next higher tank, while the overflow of the higher tank drips into the top of the lower tank. The method is suitable for the prepn. of *artificial fertilizer* contg. sulfates, carbonates, etc.

Jacketed sectional drying apparatus for preparing fish meal. HAROLD S. ROWTON and VOLKMAR W. HANIG. U. S. 1,793,638, Feb. 24. Structural features.

Forcing plants. FARBSALZ G. M. B. H. Ger. 517,115, Nov. 25, 1928. Unstable cyanides giving rise to HCN and another forcing agent, *e. g.*, NH_3 or C_2H_2, are used. $Ca(CNNH_2)_2$ and crude $Ca(CN)_2$ contg. free CaC_2 are suitable, the former being obtained by prepg. $Ca(CN)_2$ in liquid NH_3.

Insecticide. HANS WESCHE, KARL BRODERSEN and WERNER EXT (to Winthrop Chemical Co.). U. S. 1,794,046, Feb. 24. An aromatic monothiocyanate such as benzene thiocyanate is used as an active constituent of prepns. such as powders or solns.

Applying insecticides and fungicides to growing plants, etc. JOSEPH D. NEULS.

U. S. 1,792,860, Feb. 17. A porous carrier such as sawdust or pumice impregnated with a mineral oil is subjected to simultaneous distn and incomplete combustion, and the vapors thus produced are projected on trees or plants or other articles for their insecticidal and fungicidal effect. App. is described.

Seed-goods protection. VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Ger. 514,684, July 2, 1924. A prepn. for protecting seed goods from vegetable and animal blight contains sol. complex compds. or mixts. of nuclear metallized aromatic compds., with org. substitution products of NH_3. In the example, HgO is dissolved in H_2SO_4 and heated with cresol on a water bath. NaOH is added, and the ppt. dissolved in piperidine. Or pyridine and KCNS is heated with a Cu salt and the product mixed with ethylene diamine.

Seed-disinfectant composition. FOREST J. FUNK (to E. I. du Pont de Nemours & Co.). U. S. 1,793,686, Feb. 24. $HgCl_2$ is used in admixt. with a finely divided material such as bentonite to form a prepn. capable of producing relatively stable and substantially homogeneous suspensions with water.

Seed-disinfecting composition. FOREST J. FUNK (to E. I. du Pont de Nemours & Co.). U. S. 1,793,922, Feb. 24. Mercurized *o*-chlorophenol and mercurized *o*-nitrophenol are used with bentonite. Other similar mixts. also are described.

Facilitating germination of seeds. WARREN TEED SEED CO. Brit. 337,601, Nov. 15, 1928. See U. S. 1,756,488 (*C. A.* **24**, 3077).

16 THE FERMENTATION INDUSTRIES

C. N. FREY

Annual analytical report. B. LAMPE. *Z. Spiritusind.* **53**, 281-2(1930).—Report on the activity of the technical-scientific laboratories of the German alcohol manufacturers' association and the association of potato dryers. S. J.

Are asbestos-slate-lined fermentation tanks suitable for fermentation? W. KILP. *Z. Spiritusind* **53**, 268(1930). The answer is in the negative. S. J.

Absolute alcohol. F. WAGNER. *Z. Spiritusind* **53**, 260-1(1930).—A brief review. S. J.

Improvements in the manufacture of absolute alcohol. H. GUINOT. *Chimie & industrie* **25**, 26-32(1931). A description is given of the evolution of so-called azeotropic methods, which now permit of the production of pure abs. alc. directly from fermented worts by the use of the standard equipment at present used for the production of rectified 96% EtOH and at but slightly higher cost. A. PAPINEAU-COUTURE

New process of drying potatoes and the manufacture of alcohol therefrom. E. LÜDER. *Z. Spiritusind.* **53**, 251-3(1930); cf. *C. A.* **25**, 1327. An economic discussion. S. J.

Evaluation of potato flakes according to their yield of alcohol. B. LAMPE. *Z. Spiritusind.* **53**, 274-5(1930). There is no relationship between moisture content of potato flakes and yield of alc. It is necessary to score the sample for outside appearance, color, odor, uniformity, development of bacteria, moisture content, yield of alc. and starch value. Correct evaluation can be computed with these results on hand. S. J.

Composition of compressed and dried potato crumbs. B. LAMPE. *Z. Spiritusind.* **53**, 298(1930).—The compn. of potato juice was given in an earlier paper (*C. A.* **25**, 1327). The analytical results show that the pressed and dried potato crumbs contain about 40-50% of the ash usually present in potato flakes. The same relation was found for protein. S. J.

Effects of mashing methods and souring on potato flakes. B. LAMPE AND W. KILP. *Z. Spiritusind.* **53**, 267-8(1930). Two different processes were tried. The necessary proportion of malt was added in 2 portions in 1 expt. and mashed in one operation in another expt. The yield of alc. was smaller and the steam consumption was greater in case the malt was added in 2 portions, provided the mash was vigorously stirred and not allowed to form lumps. Artificial souring diminished the yield of alc. S. J.

Addition of ammonium salts to vinegar. C. AINSWORTH MITCHELL. *Analyst* **56**, 178-9(1931).—Analyses show that the practice has been revived of adding NH_4 salts to artificial vinegar to make it contain as much N as when made from malted or unmalted grain. W. T. H.

Studies on the biochemistry of zinc. Zinc and yeast fermentation. As. ZLATAROFF, M. ANDREITSCHEWA AND D. KALTSCHEWA. *Biochem. Z.* **231**, 123-34(1931). Studies made on *Saccharomyces ellipsoidens* show that $Zn(NO_3)_2$ and $ZnSO_4$ have the

same effect on fermentation. In a concn. of 0.002 *N* Zn salts stop fermentation; concns. between *N*/500 and *N*/900 inhibit it, the inhibition diminishing with dilu., and in a concn. less than 0.001 *N* there is no longer any effect. $Ca(NO_3)_2$ has the strongest stimulating action and Na succinate the strongest inhibiting action, which is still evident in dilns. of these salts of 0.0000005 *N*, but varies with their concn. The effect produced by these salts when acting alone or in a mixt. is entirely different quantitatively and qualitatively. Thus, 0.001 *N* $Zn(NO_3)_2$, which itself has no effect upon fermentation, nevertheless converts the stimulating action of $Ca(NO_3)_2$ to an inhibiting action, which becomes greater as the concn. diminishes. Likewise the presence of Zn salts increases the inhibiting action of Na succinate, and as the concn. of the latter diminishes the inhibiting effect of the mixt. increases. The strong inhibitory action of *N*/720 $Zn(NO_3)_2$ is made greater still by the presence of other salts, and together with 0.0001 *N* $Ca(NO_3)_2$ or 0.001 *N* Na succinate causes complete stoppage of fermentation. Na succinate in a concn. of 0.1 *N* decreases the inhibiting action of $Zn(NO_3)_2$, increases it in a concn. of 0.01 *N* and in a concn. of 0.001 *N* causes total cessation of fermentation. In a concn. of 0.002 *N* $Zn(NO_3)_2$ is unaffected in its toxic action by the presence of other salts. S. Morgulis

Note on the presence of Monilia in mother culture of soy sauce. Kenji Miyaji. Gifu Imp. Coll. of Agr. (Japan), *Research Bull.* 10, 5 pp.(1930) (in German).—Heretofore, *Aspergillus oryzae* has been thought to be the principal mold in the mother culture of soy sauce. M. isolated *Monilia* groups from the com. culture. These molds produce enzymes such as cellulase, amylase, invertase and tryptase. On media contg. sugar EtOH up to 2-3% is produced. In artificial media contg. NH_4 salts and glucose, the products were *d*-lactic acid and succinic acid. In $C_3H_5(OH)_3$, *l*-tyrosine and leucine media, tyrosol, *p*-hydroxyphenyllactic acid and leucinic acid were produced. K. Kitsuse

Bacterial action in the preparation of Japanese soy sauce. Kenji Miyaji. Gifu Imp. Coll. of Agr. (Japan), *Research Bull.* 9, 9 pp.(1930) (in German).—M. found not only small quantities of tyrosol and tyramine (cf. Yukawa, *J. Chem. Soc. Tokyo* 38 in soy sauce, but also identified *d*-lactic acid and *d*-*p*-hydroxyphenyllactic acid in soy sauce is a product of bacterial fermentation of soy beans and other ingredients. It is not known whether tyramine is a bacterial product or is derived from raw materials. An attempt was made to test the decompn. of the pure amino acids with bacteria in pure culture. With the use of *B. megaterium*, which is one of the bacteria participating in soy-sauce fermentation, it was confirmed experimentally that *p*-(amino-ethyl)-phenol, *i. e.*, tyramine, is a product of bacterial action upon *l*-tyrosine. *B. oxalatus* produced tyrosol and *p*-hydroxyphenyllactic acid but no tyramine from tyrosine. When *l*-leucine was used, *B. megaterium* produced small amts. of isoamylamine while *B. oxalatus* produced no amines but gave *d*-leucinic acid. K. Kitsuse

Additional malts of the 1930 season. S. Pickholz. *Brau- und Malzindustrie* 24, 7–8(1931); cf. *C. A.* 25, 1028. S. Lalin

Nitrogenous matter in malting. Léon Morns. *Bull. assoc. élèves inst. sup. fermentations Gand* 32, 62–4, 93–7(1931).—An address on the changes undergone by the nitrogenous compds. of barley in the course of malting. A. Papineau-Couture

Sidelights on copper as applied to brewing. D. M. Stewardson. *J. Inst. Brewing* 36, 369–81(1930).—An outline is given of the ores, smelting and prepn. of Cu, and the adaptability of Cu app. in the brewing processes. Peter J. F. Weber

The boiling of worts. R. Worssam. *J. Inst. Brewing* 36, 260–5(1930). Steam, either low- or high-pressure, is a more efficient and economical heating agent in boiling worts than direct firing of the kettle. Peter J. F. Weber

Barleys of the 1930 crop. R. Heuss. *Wochschr. Brau.* 47, 449–51 1930). Barleys of Germany (222 samples) and of Denmark, Bohemia, Czechoslovakia, Moravia, Hungary and Transylvania (45 samples) were analyzed and briefly discussed. W. Piratzky. *Ibid* 451–2.—Analyses of German barleys (42 samples) and foreign barleys (12 samples) are given. S. J.

Wine must in 1929 from the wine-growing districts of Nahe and Glan, Rheintal, **the Rhine district, Lahn, Rhine and Main.** A. Rößling. *Z. Untersuch. Lebensm.* 59, 629–31(1930).—Acidities and d. are given for 360 musts from the several districts. C. R. Fellers

Wine must in Baden for the year 1929. F. Mach and M. Fischler. *Z. Untersuch. Lebensm.* 59, 617–28(1930); cf. *C. A.* 24, 1699.—Approx. 470 musts were examd. for acidity and d. The low acidity and high d. are attributed to the drought and severe winter. C. R. Fellers

Wine must in 1929 from the wine-growing districts of Pillnitz, Lößnitz, Meissen

and Seussalitz. A. HEIDUSCHKA AND C. PYRIKI. *Z. Untersuch. Lebensm.* **59**, 613–5 (1930); cf. *C. A.* **24**, 1699.—The range in d. of the must was 60.7–88.4° Oechsle; titratable acids were 4.4–12.8 g. per l., and mineral constituents 2.64–5.04 g. per l. The d. averaged 4.2° higher than the av. for 1928. C. R. FELLERS

Chianti and its wines. LUIGI RICASOLI. *Atti III congresso naz. chim. pura applicata* **1930**, 285–91.—Descriptive. E. M. SYMMES

A new category of abnormal wines. CHARLES BERTIN. *Prog. agr. vit.* **94**, 564–6 (1930).—It is noted that certain normal wines do not correspond to the enological laws concerning the relative amts. of alc. and acid that should be present. F. W. M.

The influence of adjuncts on the composition of beer. E. JALOWETZ. *Brau- und Malzindustrie* **24**, 1–2(1931).—A discussion. S. LAUFER

The formation of layers in beer in storage vats. E. JALOWETZ. *Brau- und Malzindustrie* **24**, 21–5(1931).—W. Kusenak (*Tageszig Brauerei* **27**, No. 175; **28**, No 110) found that layers are formed in beer kept in storage after 4–5 weeks the layers differ in CO_2, ext. and albumin content, viscosity, acidity and p_H value. J.'s investigations agreed fairly well with K.'s findings. Methods are given for maintaining uniform compn. in stored beer. S. LAUFER

Preventing the "turning" of beer. J. RAUX. *Brasserie & malterie* **20**, 342–5, 359–62(1931).—An address. A. PAPINEAU-COUTURE

The extractives of whiskey. WM. PARTRIDGE. *Analyst* **56**, 177–8(1931).—The U. S. Pharmacopoeia states that whisky should not leave more than 0.1 g. of solids when 20 cc. is evapd. Various English books state that whisky should not contain more than 1/8 as much solids, which is probably attributable to a statement made in 1870 in Allen's *Commercial Organic Analysis* which does not hold true with respect to the whisky of today. W. T. H.

Simple universal thermostat for laboratory fermentations (FINK) **1**. [Fermentation] of the aqueous extracts from olives (CIUSA, *et al.*) **27**. Detection of iso-PrOH in brandy and spirits (REIF) **7**. Model experiments for the theory of alcoholic fermentation (CHILE, COUTSICOS) **10**. Peroxidase preparations (Brit. pat. 337,405) **11A**.

TATE, FRANCIS G. H.: **Alcoholometry**: An account of the British Method of Alcoholic Strength Determination, with an historical introduction written by the author in collaboration with George H. Gabb. London: H. M. Stationery Office. 63 pp. 3s., net. Reviewed in *Nature* **127**, 308(1931).

Device for atomizing fatty substances on fermenting liquid to keep down foam. ARNE BOYE. U. S. 1,792,963, Feb. 17. Structural features of a device designed to operate automatically according to the amt. of foam formed.

Testing saturation of barley, etc. W. & T. AVERY, LTD., W. A. BENTON and C. F. GOFF. Brit. 338,282, Sept. 26, 1929. For detg. the degree of satn. of material, such as that of barley during steeping prior to malting, a sample is centrifuged for a definite time, weighed, re-immersed, re-centrifuged and re-weighed, and these operations are repeated until 2 consecutive weighings are the same (indicating that satn. has been attained). App. is described.

Extracting the bouquet from wines and spirits. OTTO FODOR. Ger. 517,061, May 7, 1927. The constituents imparting the bouquet to wines and spirits are obtained practically free from EtOH by treating the beverages, or the mashes from which they are prepd., with adsorbents such as active charcoal or silica gel after or while reducing the alc. content, *e. g.*, by distn. The adsorption may be assisted by adding a little fatty or paraffin oil to the beverage. The bouquet substances may be recovered from the adsorbent by extn. and isolated by evapn. of the ext., and the beverage may be reconstituted by dilg. the bouquet substances with EtOH and H_2O. Examples are given.

Yeast. C. LANGEMEYER. Brit. 337,947, Oct. 24, 1928. A yeast obtained by an otherwise usual process is treated with a small quantity of K salts and albuminous substances, such as KCl or K_2SO_4 and albuminous substances derived from peanut meal, malt germ, lupins or yeast-press liquor, allowed to stand for several hrs. and then pressed. Use may be made of a mixt. of peanut meal, yeast and malt germ, digested with H_2SO_4, H_3PO_4 or lactic acid, with addn. of a small quantity of dextrose.

Hydrolyzed protein products. CHARLES N. FREY (to Standard Brands, Inc.). U. S. 1,794,370, March 3. See Can. 308,910 (*C. A.* **25**, 1922).

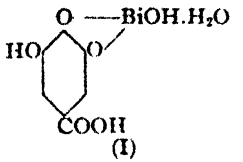
17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

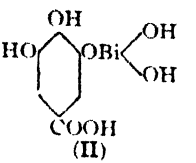
"Enfleurage" of jasmin. TRABAUD. *Parfumerie moderne* Jan., 1930; *Masloboino Zhirovoe Delo* 1930, No. 2, 84-5.—In the enfleurage or extn. by fat a high percentage of indole is obtained whereby the glucosides are split. Methyl anthranilate is also obtained; it is absent in the oil from flowers. These constituents improve the odor. One thousand kg. of flowers yields on extn. by fats 5-6 kg. of an ointment which contains 25-28% of a pure flower oil or about 1.2-1.6 kg. while the usual extn. yields 1.3-1.4 kg. of an absolute essence, the latter contg. about 30-40% pure flower oil. The enfleurage method produces a yield 2-2.5 higher than the ordinary extn. methods. Flowers left after enfleurage upon being extd. produce more oil but of a different character. A. A. BOEHTLINGK

Mechanical processes for lemon essence extraction. FRANCESCO LA FACE. *Boll staz. sper. ind. essenze* 5, 129-37, 149-59, 178-91, 212-8, 234-43(1930).—The commonly employed processes for the extn. of the essence from lemon peel are: sponge process (I), mech. rasure processes with the Cannavò (II), Speciale (III) and Calabrese (IV) machines, mech. pressing processes with Peratoner (V) and Bennet (VI) machines and a few others. Analyses were made on the samples of each of these essences with the Wilson and Young method. With the IV method there is a max. loss of essence that remains in the fruits (30.5-46%), with the I an av. of 27.5%, and with the II and III a min. loss of 10-11%. The characters of the various types of essence, the working costs and the total yields are very different; I and VI give a yellow essence, V colorless, the others green; the III essence contains 4-4.9% of fixed residue and the V only 0.3-0.65%. The mech. processes give an essence of grass odor but less odorous (the citral loss may be 25% in regard to the citral content of the sponge essence). Among the causes that may lower the citral content, the most important are the fermentations, therefore it is better to sterilize the extn. water by boiling or by adding Na benzoate

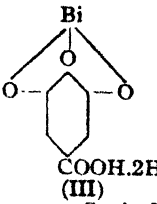
G. A. BRAVO



Colorimetric determination of adrenaline. ITALO SANSONI. *Officina* 3, 323-34 (1930).—Adrenaline can be detd. colorimetrically in pharmaceutical solns. by using standard pyrocatechol solns. with one of the following procedures. (A) Prep. standard solns. with increasing quantities of pyrocatechol, add 5 cc. of 40% Na acetate soln and 4 drops of 1% $FeCl_3$ to 5 cc. of each standard and of sample. Compare the resulting colors in test tubes or in the colorimeter in the ordinary way. Since the standard 0.08% pyrocatechol soln. and the 0.1% adrenaline soln give identical colors, the adrenaline content of the unknown soln. can be easily calcd. (B) To 2.5 cc. of each standard (prepd. with pyrocatechol) and of sample add 2 cc. of Folin reagent (10 g. Na tungstate, 8 cc. of 85% H_3PO_4 and 75 cc. H_2O are heated for 2 hrs. with a reflux condenser, and, after cooling, dild. to 100 cc. and filtered if necessary), 5 cc. of water and 4 cc. of 20% Na_2CO_3 soln., keep all the liquids for ½ hr. at 30° and then compare. The standard 0.14% pyrocatechol soln. and the 0.1% adrenaline soln give identical colors. (C) To 5 cc. of each standard (prepd. with pyrocatechol) and of sample add 2 cc. sulfanilic acid (4 g. acid and 90 cc. of 37% HCl dild. to 1000 cc.), 0.5 cc. of 1% $NaNO_2$ soln and 1 cc. of 28% NH_4OH and then compare. This reaction is the easiest and the most sensitive. The standards have good keeping qualities and give identical colors with adrenaline solns. of the same concn. The ordinary stabilizers added to the pharmaceutical solns. of adrenaline (chloretone, physiol. NaCl soln., etc.) do not interfere



G. A. BRAVO



The methods of titrating the alkaloids in the Solanaceae. EDVIGE DE CECCO *Officina* 3, 335-42(1930). The Italian Pharm., 5th Ed., suggests titrating the alkaloids in the drugs by the method of titrating the alkaloids in the drug exts. With this procedure, great errors may result from the decompn. of the alkaloids in aq. soln. and from the desiccation of the residues. Comparative expts. were made with German, English and U. S. P. on stramonium and belladonna. The U. S. P. method is the best, but the results are more accurate and very concordant if 0.01 *N* solns. are used instead of 0.1 *N* solns. in the titrations.

G. A. BRAVO

The constitution of dermatol. ANTONIO GRIPPA. *Officina* 3, 343-51(1930). G. did not succeed in prepg. the Me, Ac and Bz derivs. of dermatol; therefore the hydroxyl groups do not exist free in the mol., and the constitutions I (cf. Prunier, *J. de pharm* 2, 498 (1901)) and II (cf. Bietrix, *Bull. soc. chim.* 1, 692 (1893)) are not exact. Moreover, dermatol, when heated at 110°, loses 2 mols. of H_2O. The constitution III (cf. Cazeneuve, *Bull. soc. chim.* 1, 852 (1893)) is proposed for dermatol, as prepd. by the method of the Italian Pharm., 5th Ed.

G. A. BRAVO

Extraction of orange oil. F. J DE VILLIERS. *J. S African Chem. Inst.* **13**, 48–52 (1930). - Steam-distn. of orange peel causes some decompn. of the essential oil unless carried out in high vacuum. Alc. proved the best solvent for extn., the peel being rasped under alc. and prolonged contact being avoided. Addn. of water to the ext. causes the sepn. of a fine emulsion difficult to sep. directly by centrifuging. The particles of the emulsion are negatively charged and sepn is effected by the addn. of electrolytes. The absorption of ions by the emulsion was in the order $Fe^{...} > Ca^{..} > Na^{.}$, but the most effective coagulant was the H ion. B. C. A.

Scheme for the microchemical identification of alkaloids. J. F. H. AMELINK. *Pharm. Weekblad* **68**, 159–85(1931) The scheme consists in treating the sample with a series of alkaloidal reagents and noting the character and microscopic appearance of the reaction products. The reagents employed are $PtCl_4$, $PtCl_4$ + NaI, $AuCl_3$, $AuCl_3$ + NaBr, $HgCl_2$, $K_4Fe(CN)_6$, $K_3Fe(CN)_6$, Dragendorff's reagent (K_3BiI_6), KOH and picrolonic acid The microtechnic for extn., filtration and sublimation of the alkaloid is described in some detail The reactions are tabulated and a large no. of drawings are given showing the typical cryst forms of the reaction products. In some cases the alkaloid can be identified by a single reaction, but usually 2 or more reactions are required for identification In special cases it is desirable to make confirmatory tests by specific reactions. The table gives 78 substances, mostly alkaloids, but includes also other products commonly classed with the alkaloids, *e. g.*, caffeine, cantharidin, santonin; simple bases, *e. g.*, betaine, choline, synthetic medicinals, *e. g.*, PhNHAc antipyrine, urotropine. *Ibid* 211–6. The reactions are discussed in detail as applied to *percaine*, *α* butoxy *γ*-(diethylaminoethylcarboxamido)quinoline, and *diocaine*, di-*N*,*N'* (*p*-alloxyphenyl)acetamidine, 2 local anesthetics included in the above table. A. W. DOX

Production of new disinfection preparations of thymol and carvacrol. I. Production of thymol and carvacrol. C. PHILIPP AND PH. KUHN. *Pharm. Presse, Wiss.-prakt. Heft* **1931**, 19. - A brief survey of the principles upon which the prepn. of cymene, thymol, carvacrol and mono- and dichlorocarvacrol is based. **II. Disinfectant action of thymol and carvacrol preparations.** PH. KUHN. *Ibid.* - The results obtained in a series of expts. on the disinfectant action of thymol, carvacrol and their Cl substitution products are reported. The most valuable of the products tested proved to be chlorocarvacrol (carvasept) which can be usefully employed where phenol and thymol are indicated Its advantages lie in a higher disinfectant power, lower toxicity than PhOH and thymol, slight soly in H_2O with resultant slow resorption and good compatibility. W. O. E.

Content of mydriatic alkaloids of sun- and shade-dried Solanaceae drugs (Atropa, Hyoscyamus and Datura species). ELEMER KOPP. *Pharm. Zentralhalle* **72**, 113–6 (1931). - Expts show that the alkaloidal content of *Belladonna* and of *Hyoscyamus* is not materially affected by the manner of drying, whether in the sun or shade; with *Datura*, however, the amt. of alkaloids in shade-dried material is about 10% greater than in that dried in the sun. W. O. E.

Scientific pharmacy. XVII. Production of organotherapeutic preparations. RAPP. *Pharm. Ztg.* **76**, 260–1(1931); cf. *C. A.* **25**, 380. A discussion of the various glands, their importance in pharmacy and methods of prepn. and evaluation. W. O. E.

Alcohol number of the D.A.-B.VI. F. GRAF. *Pharm. Ztg.* **76**, 261–2(1931).—A critical examn. of the official Ger. method showing that correct results are obtainable only by a thermometric check of the distn., and not by distg. off as prescribed, 13 and 11 cc. W. O. E.

Evaluation of flores cinae D.A.-B.VI. W. BRANDRUP. *Pharm. Ztg.* **76**, 262 (1931). - The official provisional test prescribed for this drug is often inadequate in its evaluation. The following is suggested: on about 2 g. of the powd. sample in a filter pour about 5 cc. of $CHCl_3$ and evap. the filtrate to dryness in a porcelain dish. The residue, moistened with alc. KOH, should yield an orange to red color. W. O. E.

Extraction of ergot by the methods of D.A.-B.VI and U. S. P. X, with notes on ammoniated tincture of ergot, B. P. FRANK WOKES AND G. K. ELPHICK. *Quart. J. Pharm. Pharmacol.* 3, 599–625(1930).—A study has been made of the methods of prepg. liquid ext. of ergot prescribed in the Ger. and U. S. pharmacopeias. The Ger. method is on the whole less efficient than the Am. method, but the difference is much smaller than appeared from the work of Linnell and Randle. In the percolation of ergot with neutral 50% alc., as in the Ger. process, the ext. efficiency is greatly affected by the degree of acidity of the ergot, because of the phosphate and other buffering substances contained therein. With the more acid ergots (p_H below 5.5) neutral alc. may ext. the ergotoxine almost completely as it is extd. by acidified alc. (contg. 2% concd. HCl or 1% tartaric acid). With the less acid ergots (p_H above 6.0) neutral alc. may ext. less than 0.5 the amt. of ergotoxine taken out by the acidified alc. Ammoniated alc., as in ammoniated tincture of ergot B. P., gives similar results to neutral alc. Whatever process of extn. is used, the buffering substances exert considerable influence on the p_H of ext. of ergot, both during extn. and in the completed product. If this p_H is to be maintained at the optimum point for extn. and stability, as suggested by American workers, it will not be sufficient to employ a fixed proportion of acid, but control will be necessary by means of p_H detns. The defatting of ergot increases the efficiency of extn. of both neutral and acidified alc. Complete removal of fat, without loss of ergotoxine, is very difficult to secure, and so-called "defatted" ergot may still contain a considerable proportion of fat. The concn. of dil. exts. of ergot should be carried out *in vacuo* below 37° with min. exposure to air. If these precautions are taken, concn. may be continued down to a soft ext. with the loss of less than 0.5 the activity, and it should be possible to obtain from an av. sample of Spanish or Portuguese ergot a soft ext. contg from 0.5 to 1.0% ergotoxine. The variation in potency of com. soft exts. suggests that sufficient care is not taken in their manuf. In the Ger. pharmacopeial process for concg. the dil. percolate, a considerable amt. of activity may be lost in the pptn and neutralization with Na_2CO_3, and the U. S. P. method of concg. down to a soft ext. appears to give better results. W. O. E.

Biological standardization of tincture of aconite, B. P. F. J. DYER. *Quart. J. Pharm. Pharmacol.* 3, 626–36(1930). - Six tinctures of aconite were bought directly from different mfg. houses and examd. for their toxicity on rats and mice. Detns. were also made of the amt. of Et_2O-sol. alkaloid, and of total solids present in each. The examn. on rats revealed only quant. differences between the different tinctures while that on mice was complicated by the emergence of qual. differences as well. The toxicities of the different tinctures both on rats and mice varied very widely, and the relative values as detd. on rats were found to be very similar to the relative amts. of Et_2O-sol. alkaloids present. *Conclusions.*—There is no uniformity in the toxicity of different samples of tincture of aconite sold as "B. P." at the present time. The figures obtained for the % of Et_2O-sol. alkaloids were either correct or they were incorrect. If correct, then there is no need for a toxicity test of tincture of aconite, because a detn. of the Et_2O-sol. alkaloids gives a parallel result. If, however, these figures were correct, then at least 4 of the 6 tinctures purchased did not comply with the B. P. If not correct, then it may be supposed that all the tinctures complied with the B. P., and the wide variation in toxicity of the different tinctures means that a toxicity test is required. W. O. E.

(Tobacco) smoking, nicotine limits and the determination of nicotine by the method of Pfyl and Schmitt. FR. BOLM. *Z. Untersuch. Lebensm.* 59, 602–7(1930).—Aside from minor modifications, the method of Pfyl and Schmitt (*C. A.* 22, 1214) was found entirely satisfactory, and the observations on the influence of rate, intermittency etc., of the smoking on the nicotine content of the smoke, were confirmed. Several samples of nicotine-free tobacco and cigarets were examd. for nicotine content. None of the methods used in fixing the nicotine in the tobacco gave a nicotine-free smoke hence the detn. of total nicotine in the tobacco is in itself sufficient in judging the tobacco. C. R. FELLERS.

Ethereal oil from Podocarpus macrophylla, Don. I. KITSUJI NISHIDA AND HIDETAKE UOTA. *J. Agr. Chem. Soc. Japan* 6, 1078–86(1930); *Bull. Agr. Chem. Soc. Japan* 6, 82–3(1930).—By the distn. of the leaves 0.049% of ethereal oil was obtained. α-Pinene, camphene, β-pinene and cadinene were proved to exist in the vacuum distn. fractions. Caryophyllene and sylvestrene were not detected. Y. KIHARA.

A method for the germicidal assay of soaps. H. C. HAMILTON AND FRED THISTLETHWAITE. *J. Lab. Clin. Med.* 16, 391–6(1931).—A method is described in which the skin of guinea pigs is used as a field for the testing of disinfectants commonly used on the skin. EtOH applied before making injections is ineffective in any concn. A 0.5%

soln. of PhOH or tincture of I, in a 33% soln. is effective. Toilet or washing soaps are wholly ineffective. A soap base in which HgI_2 is properly incorporated in a concn. of 1% is effective. E. R. MAIN

Pyrethrum. ED. ZACHAREWICZ. *Prog. Agr. vit.* **94**, 569–70(1930).—Directions are given for cultivating the plant. The application of superphosphate is important as it increases the content of the plant's active principle, *oleoresin*. F. W. MARSH

The antiseptic power of uroselectan. G. DELEPIANE. *Boll. soc. ital. biol. sper.* **5**, 822–4(1930).—Although uroselectan has feeble antiseptic power *in vitro* in the concn. used clinically (4–6% in pyelographic tests), it definitely inhibits the growth of *B. coli* in the urine. PETER MASUCCI

The determination of some medical products by mercurimetry. AL. IONESCO-MATIU AND A. POPESCO. *Bull. sci. pharmacol.* **38**, 71–6(1931); cf. *C. A.* **24**, 5428.—From a soln. of about 1% *sparteine* mix 1 to 4 cc. with 5 cc. of the reagent of Mayer-Valzer. Centrifugalize and wash the ppt. with 1% H_2SO_4. Dissolve in 5 cc. sulfonitric reagent, applying moderate heat, add 5 cc. more and 6 cc. H_2O, boil and, after cooling, destroy the nitrous vapors with $KMnO_4$. Ppt. the Hg with Na nitroprussiate (10% soln.) and add 0.1 *N* NaCl until the turbidity disappears. One cc. NaCl soln. is equiv. to 0.01423 g. of sparteine sulfate. For the detn. of *novocaine*, 1–5 cc. of a 1% soln. is taken. The method is the same as described, but 25 cc. H_2SO_4-HNO_3 is used. The factor per cc. NaCl soln. is 0.02. The same method is used for stovaine-HCl (factor 0.0155) and for *plasmochine* soln. (factor 0.00926). With plasmochine tablets, 5 are dissolved in 10 cc. H_2O and 10 drops of H_2SO_4, filtered, brought to the vol. of 25 cc. and 5 cc. is employed for the detn. In plasmochine dragées, the substance is detd. together with quinine, the factor for the latter being 0.0066. A. E. MEYER

Some new color reactions of adrenaline. MARCEL PAGET. *Bull. sci. pharmacol.* **38**, 77–8(1931); cf. *C. A.* **25**, 532.—NaBrO reagent, diln. 1:100, produces in a soln. of adrenaline of a concn. higher than 1:1000 a color between a pale violet to intense red. A violet coloration is still observed to a diln. of 1:100,000. Adrenalone gives a yellow color. The classification of adrenaline reactions in correspondence with the mol. groups involved is shortly discussed. A. E. MEYER

A new method of determination of cocaine and its salts. JUAN A. SÁNCHEZ. *Semana méd.* (Buenos Aires) **1931**, I, 487–9.—After sapon. of the cocaine, the $PhCO_2H$ is detd. Boil 0.1 g. cocaine-HCl with 5 cc. neutral EtOH and 10 cc. 0.1 *N* NaOH for 15 min. After cooling add 10 cc. H_2O and titrate with 0.1 *N* H_2SO_4 using phenolphthalein as indicator. The factor is 0.03755 when cocaine base is used and half that much when its salts are analyzed. A. E. MEYER

Studies in tobacco chemistry. IV. Methods of tobacco smoke analysis. N. J. GAVRILOV AND A. W. KOPERINA. *Biochem. Z.* **231**, 25–32(1931); cf. *C. A.* **24**, 882.—An app. is described for absorbing all the products formed in glowing tobacco. The analyses of total N, nicotine N and NH_3 N vary only 3–4%. S. MORGULIS

Experiments on Cymbopogon nardus Rendle and on Cymbopogon martini Stapf, var. Sofia. FRANCESCO BRUNO. *Parfums de France* **9**, 8–14(1931).—*C. nardus*, planted in Italy (Palermo) on March 15, 1926, had grown to an av. height of 80 cm. on Aug. 1; it was cut and distd. on Aug. 1 and on Oct. 1, yielding 14.6 and 14.2 tons of leaves (total 28.8) per ha., which gave 0.5% and 0.4% of oil, equiv. to 73 kg. and 56.5 kg., or a total of 129.5 kg. per ha. for the 2 cuttings. The corresponding yields for 1927 (cuttings on July 26 and Oct. 12) were: 28.3 and 17.1 tons, 0.535 and 0.362%, 151.4 and 61.8 kg. per ha. Analysis of this oil in the Schimmel lab. gave: d_{15} 0.8933, α (100-mm. tube) −2°11′, n_{20} 1.4720, acid no. 0.9, ester no. 58.8, Ac no. 259–5 (= 88.6% esters), sol. in 1 or more vol. of 80% alc. Analysis of the oil distd. in 1928 gave: d_{15} 0.8926, α +1°, total geraniol 84.67%, aldehydes (citral + citronellal by Schimmel's phenylhydrazine method) 44.10%, free geraniol 30.62%, other alcs. 9.95%, citronellal (Dupont and Labaune method) 33.10%, citral and other aldehydes (by difference) 11%, sol. in 1.3 vol. of 80% alc. and in 14 vol. of 70% alc. Leaves harvested during the cold season (Dec. 18) yielded 0.25% oil (as compared with 0.535% from the July harvest) which gave the following results on analysis: d_{15} 0.872, α +1°, total geraniol 70.36%, free geraniol 32.6%, aldehydes (citral + citronellal by Schimmel's phenylhydrazine method) 52.5%, citronellal (Dupont and Labaune) 27.34%, citral and other aldehydes (by difference) 24.5%, sol. in 1 vol. of 80% alc. and in 12 vol. of 70% alc. A portion of this same harvesting was allowed to dry till it had lost 72% in wt. The dried leaves gave the same yield of oil as the fresh leaves. The drying of the leaves had the follow-

vesting on Jan. 31 (preceded by 10 days of cold weather with a temp. of about 2°) gave an oil of d_{18} 0.890, α +1.66°, total geraniol 90.18%, free geraniol 5.8%, citronellal + citral + aldehydes (by hydroxylamine) 72.1%, citronellal + citral + aldehydes (by phenylhydrazine) 71.3%, citronellal (Dupont and Labaune) 52.18%, citral + aldehydes (by difference) 19.52%, alcs. other than geraniol 32.20%, sol. in 1 vol. of 80% alc. and in 5 vol. of 70% alc. *Cymbopogon martini*. Stapf, var. *Sofia*, obtained from Bombay in 1926 and planted in Italy in March, 1927, reached an av. height of 1.20 m. by Sept. 15. Distn. of the leaves and the ends of the stalks before blossoming yielded 0.2% oil, but distn. of the whole stalks yielded no oil whatever. Distn. of leaves and blossoms harvested in Oct. yielded 0.207% oil; the blossoms alone yielded 0.35% and the leaves alone 0.112%. The oils obtained from the leaves and ends of the stalks before blossoming, and from the leaves and blossoms, resp., had d_{18} 0.9364, 0.9561; α +36°, +45.54°; n 1.48857, 1.49229; soly. in 70% alc. 1 in 1.8 vol., 1 in 2 vol.; acid no. 1.5, 2.6; ester no. 11.2, 12.1; Ac no. 130.7, 151.2; total alcs. 39.8%, 46.9%; yield per ha. 49, 61.8 kg. In 1928 the yield from the leaves and blossoms was 0.22%, equiv. to 83.4 kg. per ha. of oil of d_{18} 0.9547, α −0.66° to +49.33°, acid no. 3.3, ester no. 13.08, Ac no. 169.87–171.73, total geraniol 53.22–53.87%, free geraniol 3.63%, sol. in 3 vol. of 70% alc.

A. PAPINEAU-COUTURE

Liquorice, its extract and derivatives. A. LABO. *Rivista ital. essenze e profumi* 12, 252(1930); 13, 26–7(1931).—A review. R. SANSOME

Medicinal properties of the linden tree. G. GATTI-R. CAJOLA. *Rivista ital essenze e profumi* 13, 5(1931).—The flowers contain in the parenchyma glandules much mucilage, tannin, wax, traces of tiliacin and 0.040% of essential oil with a pleasant perfume, the compn. of which has not yet been established. It is extd. from the flowers dried in the sun. These when filled with essence are light yellow. The flowers can be mixed with flowers of the *Tilia tomentosa* and *Tilia argentea*, distinguished by the presence of star fibers, by having more petals, and a different odor. Some therapeutic uses of the essential oil of the linden tree are listed. R. SANSONE

The chemical composition of digitalis. SERAFINO DEZANI. *Giorn. farm. chim.* 80, 51–4, 57(1931).—A review. G. SCHWOCH

Determination of hypophosphites and arsenites by the mercurimetric method. AL IONESCO-MATIU AND MME A. POPESCO. *J. pharm. chim* [8], 13, 12–9(1931). The method is based on the quant. reduction of $HgCl_2$ and detn. of the pptd. Hg by the general method (cf. *C. A.* 23, 5007; 24, 5428). Accurate results are obtained in using the following equivs.: 1 cc. 0.1 *N* NaCl = 0.002204 g. $PO_2H_2Na\ H_2O$ (theory: 0.00267) = 0.0021304 g. $Ca(PO_2H_2)_2$ (theory: 0.0002145) = 0.0004966 g. As_2O_3 (by detn. and theory). S. WALDBOTT

Moisture and ash of certain official extracts (French Pharm.). H. TROTHIER. *Thesis* (Paris) 1929; *J. pharm. chim* [8], 13, 34–5(1931). The methods used and results obtained will furnish useful data on liquid and dry exts. in compiling the next French Pharm. S. WALDBOTT

A critical review of the methods for the determination of formaldehyde, and a rapid and accurate method for its determination. JAKOB BÜCHI. *Pharm. Acta Helv.* 6, 1–54(1931).—A prize essay with a list of 120 references. The following methods were critically examd.: (*a*) NH_4Cl (Smith, 1806; cf. *C. A.* 17, 946), (*b*) H_2O_2, (*c*) Na_2SO_3, (*d*) HgI_2K_2, (*e*) I. With pure solns. of HCHO, all methods except that with NH_4Cl gave concordant results after each method had been suitably modified. The presence of EtOH, Me_2CO and AcH affected results, most notably EtOH in the I method of Pharm. Helv. IV. For the detn. of HCHO in *formaldehydum solutum*, Pharm. Helv. IV, B. proposes the following modification of the Na_2SO_3 method (cf. Taufel and Wagner, *C. A.* 20, 1774): Dil. an accurate wt. of about 6 g. HCHO soln. with H_2O to 100 cc. To a 25 cc. aliquot add 3 drops of 0.1% thymolphthalein, and neutralize with *N* NaOH until a blue color appears. To the mixt. add a thymolphthalein-neutral soln. of 6.5 g. crystd. Na_2SO_3 in 25 cc. H_2O and titrate slowly to complete decoloration. Each cc. of *N* HCl is equiv. to 0.03002 g. HCHO. Results agree well with those of the H_2O_2 and I methods. In the presence of as much as 27.28% EtOH, the max. deviation is only +0.04%. With acetone in concns. below 7%, deviations are as small as those with EtOH; at 34.38% Me_2CO they are +0.40%. However, AcH in concns. above only 0.5% increased the results notably (+0.20% at 0.52%, +1.97% at 5.22%, +10.29% at 26.08% AcH). To det. HCHO in *sapo formaldehydatus*, Pharm. Helv. V, by the Na_2SO_3 method, add to 6 g. of substance 25 cc. of a 10% $BaCl_2$ soln. to remove fatty acids, fill up to 100 cc. and shake well. Treat a 25 cc. aliquot as before, except that 0.1 *N* NaOH and HCl and a neutral soln. of 2.5 g. crystd. Na_2SO_3 in 10 cc. H_2O are used (equiv. of 1 cc. 0.1 *N* HCl 0.003002 g. HCHO). For the detn. of HCHO in *spiritus*

formaldehydatus, Pharm. Helv. V, by the same method, dil. 6 g. of the fluid with H_2O to 100 cc., then proceed as with the HCHO-soap soln. S. WALDBOTT

The exactness of dosage in pharmaceutical specialties. E. SCHLUMPF. *Schweiz. Apoth.-Ztg.* **68**, 641–5(1930).—In 4 tables, deviations in % are shown between declared strength of the specialty and that actually found by the official Swedish Control Lab. (cf. *C. A.* **25**, 1334). Tablet specialties and gelatin capsules showed wide variations. S. WALDBOTT

Therapeutic preparations from generative organs. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 141,806, Oct. 20, 1927. Addn. to 134,782 (*C. A.* **24**, 1705). A water-sol. active prepn. is obtained by hydrolysing genital organs (*e. g.*, ovaries or testes) with $Ca(OH)_2$ or NaOH, extg. the hydrolysate with H_2O-insol. org. solvent, sepg. the layers and evapg. the aq. part. The residue is a stimulant and nerve tonic. Examples are given.

Therapeutic preparations from generative organs. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 141,807, Sept. 30, 1927. Addn. to 136,510. Male generative organs are extd. with H_2O-sol. and H_2O-insol. solvents and water; the aq. layer is sepd., heated with dil. AcOH, the albumin sepd. and the remainder evapd. to dryness *in vacuo*. The product is a body and nerve stimulant.

Colloidal phosphate preparation for intravenous injection. FRITZ E. BISCHOFF (to Henry J. Ullmann). U. S. 1,794,510, March 3. A substantially non-toxic prepn. not affecting the hemoglobin of the blood comprises a colloidal metal phosphate such as that of Pb together with a protective dispersing agent such as gelatin and NaCl.

Iodides of 2-aminopyridine and its derivatives. MAX DOHRN and RALPH DIRKSEN (to Schering-Kahlbaum A.-G.). U. S. 1,793,683, Feb. 24. Cl I compds. of 2-aminopyridine and its derivs. described in U. S. 1,723,457 (*C. A.* **23**, 4484) when treated with an alk. medium such as a 20% NaOH soln. undergo rearrangement to form 5-iodo-2-aminopyridine (m. 129°) and its derivs.; 5-iodo-2-ethylaminopyridine, m. 86°; 5-iodo-2-isopropylaminopyridine, b. 132–5°; 5-iodo-2-isoamylaminopyridine, m. 59–61° and b_4 145–55°; 5-iodo-2-diethylaminopyridine, $b_{2.4}$ 125–9°. These compds. may be used in *production of medicinal prepns.*

Isopropyl ether of *p*-acetylaminophenol. LAMBERT THORP. U. S. 1,793,030, Feb. 17. This compd., an analgetic, white cryst., m. 131–2°, readily sol. in alc. and ether and slightly sol. in cold water, is made by a process described in detail and may be used for treating headache, neuralgia, rheumatism, etc., to relieve pain.

Arsenated di(aminobenzyl) derivatives of methylene diguaiacol. SAMUEL L. SUMMERS. U. S. 1,793,027, Feb. 17. A compd. of the empirical formula $C_{33}H_{36}O_{10}$-

N_3As_3 which is insol. in water but sol. in MeOH, EtOH and acetone is obtained by a process described in detail and is suitable for combating syphilis and sleeping sickness.

Iodinated, acetylated condensation products of the di(aminobenzyl) derivatives of methylenediguaiacol with terpin hydrate. SAMUEL L. SUMMERS. U. S. 1,793,028, Feb. 17. Products insol. in water but sol. in alc. and which may be used as antiseptic, antineuralgic, antitubercular and anticatarrhal remedies are described with details of manuf.

Neutral calcium salt of inositolhexaphosphoric acid. "CRISTALLO" A.-G. Swiss 141,522, Dec. 8, 1928. Vegetable matter rich in inositolhexaphosphoric acid and its salts are extd. with water and the neutral Ca salt pptd. from the ext. by addn. of $CaCO_3$. The Ca salt is filtered off and used in therapy. The remaining liquid is rich in vitamins which are unaffected by the presence of the carbonates, and can also be used for medicinal purposes.

Granular anhydrous citric acid. RICHARD PASTERNACK and FRANKLIN G. BREHMER (to Charles Pfizer & Co.). U. S. 1,792,657, Feb. 17. Citric acid is dehydrated by drying at temps. of 35–50°, in order to obtain a product suitable for tablets, effervescent salt compns., etc.

Isolation of scillarene A from squills. CHEM. FAB. VORM. SANDOZ. Swiss 142,364, Feb. 19, 1929. Addn. to 134,217 (*C. A.* **24**, 1706). The cryst. almost H_2O-insol. ext from squills, which has a strong action on the heart and contains glucoside and tannoid, is extd. with water and the insol. part added to a mixt. of water and org. solvent. This is treated with a tannin-pptg. agent to remove the tannin and scillarene A is obtained from the filtrate.

Anti-syphilis preparation. SALO BERGEL. Ger. 502,655, Feb. 19, 1925. Virulent syphilis spirochetes are killed, dissolved in lecithin emulsion and the resulting prepn injected into the pleural or abdominal cavities or in the ear veins of animals. The blood, abdominal and pleural exudations, lymphatic glands, milk, thyrus and ovaries are then extd. with glycerol and soda or dil. acid soln. to obtain the anti-syphilis prepn.

"Cancer remedy." H. LEITNER. Brit. 337,797, July 8, 1929. Gall bladders of animals are extd. with alc., ether or other solvent and the ext. is evapd. to dryness and the resulting product is preferably dissolved in an aq. soln. of KCl or other suitable K compd. and used for injection into the affected part.

Vaccines. PHILALETHES KUHN. Ger. 517,204, Feb. 12, 1929. The usual bacteria are cultivated on nutrient mediums which are inoculated also with filtrates from cultures of the known ameboid forms. The coccoid growths so obtained are killed or enfeebled by the action of heat or disinfectants.

Treating blood, bandages, etc., to prevent bacterial decomposition. I. G. FARBENIND. A.-G. Brit. 337,473, May 1, 1929. The materials are treated with small addns. of substances such as methylenebis-2,4-dichlorophenol, the condensation products of formaldehyde with 2 mol. proportions of *p*- or *m* chlorophenol, the condensation products from *p*-chlorobenzaldehyde or *p*-diethylaminobenzaldehyde and 2 mol. proportions of *p*-chlorophenol, a product obtained by treating the condensation product of cyclohexanone and 2 mol. proportions of phenol with a glacial HOAc soln. of Br or with a K bromate-bromide soln., or a product obtained by heating 2,6-dimethylol 4-chlorophenol with 4-chlorophenol in the presence of 50% H_2SO_4.

Filter for essences, etc. MARINO PISANI. Swiss 142,143, July 29, 1929. The filter is particularly suitable for removing particles of water contained in the essence, etc.

Medicating tobacco with iodine. FRANK P. STRICKLER. U. S. 1,793,723, Feb. 24. I is first converted into a fluid state, as by vaporization or dissolving in alc. and is caused to crystallize in contact with tobacco to render the latter suitable for use as a therapeutic source of I.

Tobacco smoke treatment. H. PAFFGEN. Brit. 338,006, Nov. 19, 1929. Poisonous constituents of tobacco smoke such as nicotine, pyridine and "brenzole" are separated by passing the smoke through a dry absorption medium such as activated C or silica gel which has been previously satd. with a volatile substance of suitable character to prevent absorption of aroma-imparting substances also (as by use of smoke from combustion of nicotine-free tobacco waste, peppermint oil, NaOH, Na_2CO_3, sucrose, NaCl, tannic or barbituric acid, O_2 or Na hyposulfite, or by merely leaving 20–25% of water in silica gel if this is used).

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

The concentration of weak nitric acid. G. PAYRAS. *Rev. gén. mat. plastiques* **6**, 147–51(1930).—A description is given of the Chem. Construction Co.'s Fr. pat. 656,108 (*C. A.* **23**, 4026). A. PAPINEAU-COUTURE

Vanadium as a catalyst for sulfuric acid manufacture in America. ENSIO ALHOPURO. *Acta Chemica Fennica* **3**, 112–4(1930).—The characteristics of V catalysts now used in plant operation are given. The best results are obtained by the Selden V mass and the new converter developed by A. O. Jaeger, which give as high as 98% conversion. In present-day plant operation V gives a higher av. conversion than Pt, because Pt is contaminated with traces of As and Cl. The price of Pt is 184–253 times the price of V, but the high return value of Pt catalysts and the high price of licenses for V catalysts make this proportion lower. H_2SO_4 plants which were operated or built in 1929 and which use the Selden converter system have a total capacity of more than 300,000 tons of H_2SO_4 per year. The total production of H_2SO_4 by the contact process in the U. S. during the same year was 1,870,000 tons as 100% acid. S. A. KARJALA

Potash. GEO. W. STOCKING. *Chem. Markets* **28**, 247–52(1931).—The industry in Germany is described. E. H.

A study of the properties of polyhalite pertaining to the extraction of potash. VI. Experiments on the production of potassium chloride by the evaporation of leach liquors from decomposition of uncalcined polyhalite by boiling saturated sodium chloride solutions. H. H. STORCH AND F. FRAAS. Bur Mines, *Rept. of Investigations* **3062**, 7 pp.(1931); cf. *C. A.* **25**, 1338.—Evapn. of 90% of the H_2O, interspersed with 3 crystn. steps, will yield 78% of the K_2O as crude KCl, the bulk of the impurities being NaCl. This product may be refined readily by recrystn. to produce pure KCl. A preliminary estimate indicates about $20 a ton as the cost of production at the plant. A. H. E.

The acids and acid salts which contaminate cream of tartar. FILIPPO PERCIABOSCO. *Atti III congresso naz. chim. pura applicata* **1930**, 520–5.—Some cream of tar tar contains appreciable quantities of $Ca(C_4H_5O_6)_2$ instead of KCl. E. M. S.

Quinquennial review of the mineral production of India for the years 1924 to 1928. Phosphates. E. H. PASCOE. *Records Geol. Survey India* **64**, 413–21(1930).—Apatite is known in many parts of India, some deposits assaying 20–25% P_2O_5. Nodular deposits of lime phosphate also occur. ALDEN H. EMERY

A brief history of the world's phosphate rock production. A. N. GRAY. *Superphosphate* **4**, 25–46(1931).—Historical notes relating to the discovery of phosphate deposits and the early production of phosphate rock in all parts of the world are given. The world's annual production of phosphate rock by countries is given for the years 1847 to 1929. K. D. JACOB

Dehydration of salts of phosphoric acid. S. S. DRAGUNOV. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 409–16(1930). Graphs show the transformations of the salts of Na, K and Ca or phosphoric acid upon drying. From these it is possible to judge the % of pyro- and meta-modifications formed, as well as the speed of the transformations at various temps. With the loss of H_2O of crystn. $CaHPO_4.2H_2O$ becomes less sol. in citrate soln. At 100° only 4% of the H_2O of crystn. was lost in 1.5 hrs. At 150° 19% was lost in 20 min. It is important not to dry phosphate very much above 100° for any period of time (not more than 30–50 min. at 100°). Ca metaphosphate, insol. in acid, can be hydrated in the autoclave at high pressures and brought back to the sol. state. J. S. JOFFE

Utilization of the gases obtained in the process of volatilizing phosphorus and the production of soluble phosphates. A. P. DUNAEV. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 397–409(1930).—The relation of H_2O and O from the air to the system: P, PH_3, CO, H, in which a reaction of selective oxidation of generator gas takes place was investigated. A modification of the app. used by Britzke and Pestov (cf. *C. A.* **24**, 208) was necessary. A description and drawing of the new app. are given. The exptl. data obtained show that the oxidation of P with H_2O over CaO at a temp. from 550° to 950° is completed to phosphoric acid at fairly rapid velocity of the gas stream. Very little PH_3 is found in the gases, and the sum of CO + H is not decreased. The materials used for oxidation contained no phosphates. In the oxidation of the gases with air no excess of O was necessary in the process, except what was needed for the oxidation of P. At the lower limits of temp. no O is used up by the CO. The generator gases used in this manner can be used again for heating or other purposes. After

the process was worked out with lime, NaCl was tried. On account of the volatilization of the NaCl and even the Na phosphates formed, it was necessary to keep the temp. between 400° and 500°. With H_2O no oxidation of P took place, but with O it did, and the generator gases were free from P, but slightly diluted with N. J. S. J.

Calcium arsenate. Economic data regarding its development in Mexico. PABLO HOPE Y HOPE. *Rev. quím.* **6**, No. 2, 11–9(1930); cf. *C. A.* **25**, 1039.—As_2O_3 can be obtained from smelters in Mexico, but is unprofitable. If made into $Ca_3(AsO_4)_2$, 2,200,000 kg. could be used on cotton fields in Mexico. E. M. SYMMES

Magnesium compounds (other than magnesite). PAUL M. TYLER. Bur. Mines, *Information Circ.* **6406**, 19 pp.(1931); cf. *C. A.* **25**, 561.—Properties, uses, methods of production, domestic and foreign production, imports, exports, prices and manufacturers of $MgCO_3$, $MgSO_4$, calcined magnesia and $MgCl_2$ are discussed. A. H. E.

Separation of the constituents of sylvinite in the form of carbonates. EDOUARD URBAIN. *Compt. rend.* **192**, 232–3(1931).—Almost complete pptn. of K in the form of acid carbonate of K and Mg may be obtained, and the Cl of KCl may be removed in the form of NaCl, by using $NaHCO_3$, according to the reaction, $MgCO_3 + NaHCO_3 + KCl = MgCO_3KHCO_3 + NaCl$. This reaction may be applied to com. sepn. of K and Na in the mixt. of chlorides known as sylvinite, which is a most important mineral in potash mines. After sepn of the solid phase the soln. is treated to recover $NaHCO_3$. The cycle of operations permits quant. recovery of K_2CO_3 and Na_2CO_3 from sylvinite. ALICE W. EPPERSON

The economic significance of zirconium and its compounds. J. F. CORRIGAN *Ind. Chemist* **7**, 97–100(1931). E. H.

Extraction of beryllium, cesium and rubidium from beryl. C. JAMES, H. C. FOGG AND E. D. COUGHLIN. *Ind. Eng. Chem.* **23**, 318–20(1931).—The finely ground mineral is fused with CaO, and the resulting slag is ground, decompd. with H_2SO_4 and heated to dehydrate the SiO_2. The mass is stirred with hot water, and the filtrate is concd. to ppt. out K, Cs and Rb alums. The remaining $Al_2(SO_4)_3$ is removed as NH_4 alum, and the Fe, after oxidation, is pptd. with dil NH_4OH, the last traces being removed by H_2S under slight pressure. The Be is then pptd. as the basic carbonate by the addn of $(NH_4)_2CO_3$. The method can be adapted to the extn. of Be from other silicate minerals. K. D. JACOB

Activated carbons. G. SIMONIN. *Caoutchouc & gutta-percha* **26**, 14,357–9, 14,468–70, 14,516–9, 14,551–3, 14,594–5, 14,632–6, 14,701–2, 14,742–4, 14,788, 14,821(1929); **27**, 14,866–8, 14,903–4, 14,940–1, 14,983–5, 15,022–3, 15,064–5(1930). After the important phys. properties of activated carbons are described it is shown that the activity does not depend to any appreciable extent upon the nature of the gas from which the vapor is removed. If care is taken to avoid too high temps., it is possible to recover MeOH, EtOH, AcMe, Et_2O, EtOAc and CS_2 unaltered from activated carbons in which they have been adsorbed from air. The most rapid method for expelling the adsorbed vapors from carbons, without chem. alteration, is by treatment with steam. Below 130° the steam may be adsorbed to some extent, but above this temp. it is possible practically to avoid such adsorption. Investigations of the tarry matter retained by the carbons after removal of C_6H_6 from coal gas showed that surprisingly little real tar was present, probably because of rapid resinification of the major portion of such small quantities as may be present in the gas, by contact with the charcoal. Inactivation of carbons in the removal of C_6H_6 by coal gas is attributed to the effect of S, which converts the active C mols. into CS_2. Reactivation by calcination before and after treatment with HCl is explained tentatively by the decompn of the CS_2 by Fe naturally present. The acid not only decomposes the FeS formed in the first calcination but brings about a uniform and intimate dispersion of the regenerated Fe salt in readiness for the second calcination. Similarly, it is possible to remove the inactivating S and so to revivify the C by impregnation with $FeCl_3$ soln., followed by heating, *e. g.*, for 2 hrs. at 900°. B. C. A

A western nitrogen-fixation plant. G. N. WESTBY. *Ind. Eng. Chem.* **22**, 1099–1103(1930).—A description is given of the unique plant of the American Nitrogen Products Co., which was destroyed by fire in 1927. Nitrites were manufactured by the arc process and the details of operation are described. The final product contained 96.5–99.0% $NaNO_3$. J. R. ADAMS

The synthesis of ammonia from its elements in electric discharges. M. ALSFELD AND E. WILHELMY. *Ann. Physik* **8**, 89–123(1931).—The yield of NH_3 obtained by passing a 3:1 H_2:N_2 gas through a silent discharge in a Siemens tube has been detd. at temps. of 25° to 300°. The rate of reaction increases slowly with the temp. up to 130° and rapidly from there to 300°. The sudden change in temp. coeff. at about the crit.

temp. of NH_3 is tentatively explained as due to a sudden decrease in the no. of NH_3 mols. adsorbed at such points on the surface of the Siemens tube as to inhibit NH_3 formation. Townsend, corona, glow and arc discharges were compared as regards their effectiveness in synthesizing NH_3 in a stream of H_2-N_2 gas passed through them. NH_3 was detd. in all cases by titration. In the Townsend discharge no NH_3 was obtained. In the neg. corona the yield of NH_3 was const. from 300 to 780 mm. pressure at a given c. d.; in the glow discharge at pressures below 300 mm. it increased linearly with decreasing pressure. At 760-mm. pressure, NH_3 formation in a corona discharge increased linearly with the current until an arc was formed; it then decreased markedly. In the glow discharge the most rapid rate of synthesis occurred in the cathode region; the pos. column was less active. Fe, Cu and W as cathode materials all produced about the same yield of NH_3; Pt cathodes were 30% more effective, possibly because of some synthesis occurring on the Pt between H atoms and N_2 mols. In the neg. glow, the yield of NH_3 increased linearly with the current and for a given c. d. increased with the rate of gas passage; it decreased slightly as the cathode temp. was increased. In the anomalous cathode fall, the yield of NH_3 per unit current was greater than in the normal cathode fall. The max. rate of NH_3 synthesis was found in a gas mixt. contg. 60% N_2 and 40% H_2. At the same compn. a min. in the cathode fall was noted. P. H. EMMETT

The use of pyrethrin against bed bugs. ALBERT GUILLAUME. *Bull. sci. pharmacol.* **38**, 80–4(1931). A concd. soln of pyrethrins in MeOH dild. with 25 parts of H_2O proved to be a very effective spray against bed bugs. The eggs are not destroyed. For the extinction, the buildings must be treated 3 times a year: in March–April, in July and in August–September. A. E. MEYER

Utilization of the aqueous extracts from olives [recovery of KCl] (CIUSA) **27.** $NaHCO_3$ (Brit. pat. 338,007) **15.** Apparatus for catalysis [in oxidation of NH_3] (Swiss pat. 141,303) **1.**

Nitric and sulfuric acids. I. G. FARBENIND. A.-G. Brit. 337,406, June 13, 1929. In simultaneous production of HNO_3 and H_2SO_4 by scrubbing gas mixts contg. N and S oxides with sulfuric or nitrosylsulfuric acid, as described in Brit. 301,232 (*C. A.* **23**, 4026), a sufficient proportion of N oxides is present that all the SO_2 is converted into H_2SO_4 or nitrosylsulfuric acid or a mixt of H_2SO_4 and HNO_3. Various details of procedure are described.

Sulfurous acid. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 142,731, May 15, 1929. Concd. H_2SO_3 is prepd. from gases contg. SO_2 by absorbing the SO_2 by water and aromatic amines, driving off the SO_2 by heating and reabsorbing in water.

Phosphoric acid. KUNSTDÜNGER-PATENT-VERWERTUNGS A.-G. Swiss 141,866, Apr. 3, 1929. H_3PO_4 soln is obtained by causing mineral acid to react with crude phosphates and pptg. the Ca of the crude phosphate by sulfate ions. Examples are given. Cf. *C. A.* **24**, 471.

Ammonia synthesis. LOUIS C. JONES (to Chemical Engineering Corp.). U. S. 1,794,903, March 3. The mixt. of H and N for NH_3 synthesis is purified by circulating the gases under pressure in contact with a catalyst and introducing CO_2 into the circulating system after compression and before catalysis, to react with gases and convert impurities in the system into solid products, which latter with CO_2 are simultaneously removed (suitably as $(NH_4)_2CO_3$ deposited on Raschig rings) while maintaining a continuous circulation of the gases under pressure through the system as the gases pass to the catalyst. Cf. *C. A.* **24**, 4123.

Ammonia synthesis. HERBERT A. HUMPHREY (to Atmospheric Nitrogen Corp.). U. S. 1,794,231, Feb. 24. Solid carbonaceous fuel is burned in the presence of steam, the gaseous products are subjected to catalytic action to cause reaction of CO with H_2O to form a volume of H substantially equal to that of the CO, a proportion of 3:1 between the H and N is established, O compds. are removed from the gas mixt. and the latter is catalyzed to convert part of the gases into NH_3, the NH_3 is sepd. and unconverted gas is returned to the NH_3-forming catalyst through a closed, periodically bled, circulatory system. The air and steam used with the fuel in the first step of the process are highly preheated and a temp. of about 1300° is maintained in the gasification zone. The resulting gaseous products are withdrawn from the burning fuel and heat from them is transferred to the entering air and steam while contact of the gaseous products with colder solid fuel is prevented. A substantially CH_4-free gas is thus produced which lengthens the periods between the bleedings required.

Ammonia-air mixture. HARRY PAULING. Ger. 491,961, Oct. 16, 1926. A homo-

geneous NH_3-air mixt. is obtained by absorbing the NH_3 in a circulating water current and then blowing air through the soln. App. is described. Cf. *C. A.* **25**, 1041.

Catalytic apparatus suitable for ammonia oxidation. C. TONIOLO and "AZOGENO" (SOCIETÀ ANON. PER LA FABRICAZIONE DELL'AMMONIACA SINTETICA E PRODOTTI DERIVATI). Brit. 337,680, July 25, 1929. In app. comprising a plurality of superposed layers of Pt or other suitable metallic gauze, the layers first impinged upon by the reaction gases are of coarser mesh than the subsequent layers which are less subject to attack by the gases. Various details of construction are given.

Working up mixtures containing carbon dioxide and ammonia. I. G. FARBENIND. A.-G. (Ernst Jänecke and Erich Rahlfs, inventors). Ger. 514,893, Nov. 6, 1929. Mixts. contg. CO_2 and NH_3 or their compds., especially the mixt. resulting from the prepn. of urea from NH_2COONH_4, are prepared by treating the mixt. with liquid NH_3. Thus, a mixt. of urea, NH_2COONH_4 and water is washed with liquid NH_3 at —36°, giving a soln. of urea and water in NH_3 and a pure NH_2COONH_4 residue. The urea is then recovered by evapn.

Apparatus for production of ammonium salts. "MONTECATINI" SOCIETÀ GENERALE PER L'INDUSTRIA MINERARIA ED AGRICOLA. Swiss 142,051, June 7, 1929. See Brit. 313,446 (*C. A.* **24**, 1186).

Cyanamides. N. CARO and A. R. FRANK. Brit. 338,023, Dec. 6, 1928. In prepg. cyanamides of Ca or Mg or both by reaction of the corresponding carbonates and NH_3 as described in Brit. 279,811 (*C. A.* **22**, 3024), the removal of the water produced in the reaction is accelerated by substances such as C, carbonaceous materials or P_2O_5 which are preferably mixed or briquetted with the starting materials. When C or carbonaceous materials are thus used, oxides or compds. forming oxides on heating may be substituted for the carbonates, and when P_2O_5 is used a composite *fertilizer* is obtained. Cf. *C. A.* **25**, 1041.

Phosphates and hydrogen. BAYERISCHE STICKSTOFF-WERKE A. G. (Vladimir N Ipat'ev, Nikodem Caro and Albert R. Frank, inventors.) Ger. 514,890, Mar 27 1928. See Brit. 308,684 (*C. A.* **24**, 472).

Nitrogen oxides, etc. N. CARO and A. R. FRANK. Brit. 337,847, Aug. 13, 1929. N_2O_4 or HNO_3 in concd form is obtained from mixts. contg. N oxides, O and water vapor (such as products of NH_3 oxidation) by a 3 phase process in which part only of the water is first removed without much oxidation, residual water is sepd. after or during oxidation (which is promoted by lowering the temp.) as a tetroxide contg. HNO_3 of low water-vapor pressure, while in the third phase the gas may be cooled or treated with substances which lower the vapor pressure of the tetroxide or have absorbing properties. Numerous details of procedure are given.

Precipitating metals as sulfides. NIELS C. CHRISTENSEN. U. S. 1,793,906, Feb. 24. Solns. of metals, the sulfides of which are sol. in such solns if slightly acid, e. g. solns. contg Zn, Fe and Mn, are treated simultaneously with $CaCO_3$ and H_2S to ppt the metal sulfides and form CO_2 and the latter is used for treating a $Ca(SH)_2$ soln. to form H_2S and $CaCO_3$ for further use in the process to ppt. addnl. metal

Purifying zinc salt solutions. I. G. FARBENIND. A.-G. Brit. 337,822, Aug. 8, 1929. Solns. obtained from chlorinated burnt pyrites are freed from Fe by oxidizing the latter with an alk. earth chlorate such as $Ca(ClO_3)_2$ and then pptg. with quicklime Cu is first removed by addn. of Fe.

Ammonium sulfate. UNION CHIMIQUE BELGE, SOC. ANON. Brit. 338,373, May 17, 1929. In prepg. $(NH_4)_2SO_4$ as described in Brit. 307,037 (*C. A.* **23**, 5281), with pptn. of the sulfate as crystals by addn of NH_3, the pptn. is localized in a part of the app. in which the ammoniacal soln. is mixed with a large quantity of cooler satd. soln., and a portion of this soln. is continuously circulated through a cooler so as to withdraw the heat caused by the soln. of the NH_3. Various details of app. are described. Cf. *C. A.* **24**, 715.

Decomposing ammonium sulfate. WILHELM BERTELSMANN and ALFRED C. BECKER. Ger. 517,495, Apr. 8, 1928. The thermal decompn. of $(NH_4)_2SO_4$ to NH_3 and NH_4HSO_4 is effected in vessels made of SiO_2. Shallow vessels are preferred. The temp. should be maintained above the m. p. of the sulfate melt. Addnl. details are given.

Barium aluminate. KALI-CHEMIE A.-G. (Fritz Rothe and Hans Brenek, inventors). Ger. 514,891, July 31, 1926. Aluminiferous material is heated with $BaSO_4$ to a temp. of at least 1000° in a current of steam and oxidizing or indifferent gas. Heavy spar may be used as the starting material in such amt. that besides the $Ba_3(AlO_3)_2$ formed, there is also produced silicates of the types $BaSiO_3$ or Ba_2SiO_4 or the corresponding Ti compds. In an example, 100 parts of heavy spar contg. 92.63% $BaSO_4$ and

3.72% SiO_2 are mixed with 56 parts bauxite contg. 52.86% Al_2O_3, 2.71% SiO_2 and 2.84% TiO_2. The mixt. is then heated to 1200° in the presence of steam and air, producing $Ba_3(AlO_3)_2$ and $BaSiO_3$. Other examples are given.

Barium carbide. INTERNATIONAL INDUSTRIAL & CHEMICAL CO., LTD. Brit. 338,003, Nov. 21, 1928. See Fr. 682,479 (*C. A.* **24**, 4362).

Calcium nitrate. APPAREILS ET EVAPORATEURS KESTNER. Ger. 514,589, Mar. 21, 1928. In the prepn. of $Ca(NO_3)_2$ from $CaCO_3$ and HNO_3, the $CaCO_3$ is loaded into a tower mixed with granular substance not acted on by the HNO_3, to ensure a passage for the acid through the mass. App. is described. Cf. *C. A.* **24**, 5442.

Calcium oxide. CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE G. M. B. H. Ger. 514,715, July 19, 1927. CaO, prepd. by heating $Ca(OH)_2$ to 600–800° in a gas current, can be used as a dehydrating agent for liquids or molten substances by mixing therewith. Thus, 95% alc., if heated with CaO prepd. as above, reaches a purity of 99.6% in about 15 min. Other examples describe the dehydration of Na alcoholates by CaO as thus prepd.

Siliceous calcium oxide compounds. FRIEDRICH PISTOR. Ger. 514,742, Aug. 7, 1927. Sol. dry compds. are obtained by adding CaO to concd. solns. of siliceous substances. Thus, burned lime is added to Na or K water glass. The products are used in the cold cement, dyeing and artificial mass industries.

Dicalcium phosphate. ERICH THILO and ADOLF HEICKE. Ger. 517,181, Feb. 12, 1928. See Fr. 677,191 (*C. A.* **24**, 3091).

Solid carbon dioxide. AKT.-GES. DER MASCHINENFABRIKEN ESCHER, WYSS & CIE. Swiss 141,393, Oct. 19, 1929. Liquid CO_2 under pressure is allowed to expand in stages. Cf. *C. A.* **24**, 4362, 4363.

Solid carbon dioxide. MIDDEN-EUROPEEISCHE OCTROOIMAATSCHAPPIJ. Ger. 514,717, Sept. 4, 1928. App. for suddenly allowing liquid CO_2 under pressure to expand to form CO_2 snow, and for allowing further reduction of pressure to form CO_2 ice is described. Cf. *C. A.* **24**, 1474.

Carbon dioxide from limestone. P. BROTHERHOOD, LTD., H. M. DUNKERLEY and CARBON-DIOXIDE CO., LTD. Brit. 338,369, Nov. 19, 1929. Limestone from a crusher is placed in retorts fed with steam from a boiler which is heated by waste heat from the retort furnace, and the mixt. of steam and CO_2 from the retort is used to work a prime mover, exhaust steam is condensed, and the CO_2 is collected. App. is described.

Carbon disulfide. EBERHARD LEGELER and HERMANN KOB (to I. G. Farbenind. A. G.). U. S. 1,793,181, Feb. 17. Various details are described of app. comprising an elongated main retort adapted to contain a charge of C, at least one elongated supplementary retort positioned along and in contact with the main retort in the same heating chamber, and a device for introducing liquid S at one end of the supplementary retort and for leading superheated S vapors from the opposite end of this retort into the main retort.

Carbon disulfide. EBERHARD LEGELER and EUGEN FISCHER (to I. G. Farbenind. A. G.). U. S. 1,795,132, March 3. See Brit. 333,090 (*C. A.* **25**, 564).

Carbon disulfide. CHEM. FAB. KALK G. M. B. H. and HERMANN OEHME. Ger. 507,337, July 9, 1929. CS_2 is prepd. by leading a mixt. of H_2S and CO_2, with or without inert gases such as N, over glowing C. The initial gas may be obtained from coal distn. gases by washing with water. Cf. *C. A.* **24**, 2555.

Iron-free chromic chloride from ferrochromium. I. G. FARBENIND. A.-G. (Johannes Brode and Carl Würster, inventors). Ger. 514,571, Sept. 11, 1925. Granulated Fe-Cr is heated to 300–600° in a heat-insulated container in a current of Cl and the temp. maintained at such a value that the $FeCl_3$ formed sublimates, leaving $CrCl_3$. An example is given.

Magnesium carbonate; ammonium sulfate and chloride. KALI-CHEMIE A.-G. Ger. 517,496, Oct. 17, 1928. The manuf. of $MgCO_3.3H_2O$ and $(NH_4)_2SO_4$ by treating a soln. of $MgSO_4$ with $(NH_4)_2CO_3$ is effected in two stages, the first stage involving the reaction $MgSO_4 + 2(NH_4)_2CO_3 \longrightarrow (NH_4)_2SO_4 + (NH_4)_2CO_3MgCO_3.4H_2O$. The double salt is filtered off and treated with a soln. of $MgSO_4$ to effect the reaction $(NH_4)_2CO_3MgCO_3.4H_2O + MgSO_4 \longrightarrow 2MgCO_3.3H_2O + (NH_4)_2SO_4$. $MgCl_2$ may be treated similarly, with production of NH_4Cl. The products are purer than those obtained when the reaction is effected in one stage. An example is given.

Magnesium sulfate. EMILIO RODOLFO. Swiss 142,436, May 16, 1929. $MgSO_4$ is recovered from the waste water of artificial silk manuf. by addn. of $Ca(OH)_2$ which causes pptn. of $CaSO_4$, $Mg(OH)_2$ and $Zn(OH)_2$. The ppt. is sepd., suspended in water, and treated with CO_2, to ppt. $MgSO_4$. Na_2SO_4 may also be recovered from the residual liquid.

Magnesium sulfate solution. KALI-CHEMIE A.-G. Ger. 514,590, Nov. 30, 1929. Hot highly concd. $MgSO_4$ soln. is prepd. by forming an unsatd. soln. of the salt from natural kieserite and satg. with anhyd. kieserite.

Potassium, calcium and magnesium sulfates from materials such as polyhalite. EUGENE P. SCHOCH. U. S. 1,794,552, March 3. Ore such as polyhalite is dehydrated by heating, K_2SO_4 and $MgSO_4$ are extd. with hot water, undissolved $CaSO_4$ is sepd. from the soln., K_2SO_4 is crystd. from the soln. and sepd. and the soln. is further treated for recovery of $MgSO_4$. U. S. 1,794,553 relates to a similar process. Numerous details of procedure are given.

Potassium and magnesium sulfates from polyhalite. EUGENE P. SCHOCH. U. S. 1,794,551, March 3. After dehydrating polyhalite to remove its H_2O of crystn., the material is extd. with hot water to produce solns. contg. over 5% of anhyd. salts.

Potassium nitrate. FÉLIX JOURDAN. Swiss 141,306, Mar. 30, 1929. KNO_3, with $Al(NO_3)_3$, $Fe(NO_3)_3$, etc., is obtained by treating leucite with a mixt. of N-O vapor, HNO_3 vapor and water vapor.

Sodium carbonate. W. MANN. Brit. 337,401, July 30, 1929. Finely cryst. soda is made by mixing, in an edge runner mill, finely ground Solvay soda with a suitable proportion of water.

Sodium sulfide. WOLF J. MÜLLER and FRIEDRICH KLEMA. Ger. 514,954, May 15, 1928. See Austrian 116,564 (*C. A.* **24**, 2844).

Titanium dioxide. SIMON J. LUBOWSKY. U. S. 1,793,501, Feb. 24. A finely ground mixt. of rutile and magnesia is heated to form a Mg titanate, followed by acidification with H_2SO_4, chilling the soln. to deposit $MgSO_4$, removal of the mother liquor and heating it to a high temp. to produce metatitanic acid by hydrolysis with regeneration of H_2SO_4, and the metatitanic acid is washed and calcined.

Zinc carbonate and oxide. I. G. FARBENIND. A.-G. Brit. 337,792, Aug. 7, 1929. A soln. of a Zn salt such as $ZnCl_2$, of a concn. less than 1.5 *N*, is added in slight excess to an alkali metal carbonate soln. of a max. concn. of 1.5 *N* at a temp. of 60-70°, the $ZnCO_3$ ppt. formed is filtered off, washed, dried, ground to pass through a wire sieve of 350 mesh per linear in. and then calcined below redness (suitably at 350°).

Crystals of materials such as metals or salts. PERCY W. BRIDGMAN. U. S. 1,793,672, Feb. 24. A seed crystal is placed adjacent molten substance and a portion of the seed crystal is melted and the surface of solidification is advanced from the seed crystal into the substance. An app. is described.

Borax crystallization. ROBERT B. PEET (to American Potash & Chemical Corp.). U. S. 1,792,863, Feb. 17. An emulsion colloid such as oleic acid is added to an aq. soln. which ppts. substantially only borax on cooling and the soln. is cooled while being agitated, to ppt. borax. The added colloid prevents aggregation of the pptd borax crystals.

Treating crude sylvinitic potash salts containing kieserite. THEODOR THORSELL and AUGUST KRISTENSSON. U. S. 1,794,259, Feb. 24. The kieserite in the crude material is hydrated and the salts are treated with an ammoniacal soln. of NH_4Cl, the K_2SO_4 contg. Na_2SO_4 is removed and the mother liquor is treated with CO_2 for pptn. of Mg NH_4 carbonate. The mother liquor remaining is cooled to remove a portion of the NH_4Cl present and the liquor still remaining is treated with CO_2 to ppt. $NaHCO_3$. U. S. 1,794,260 describes a process for the production of K_2CO_3 from crude sylvinitic salts, with simultaneous production of Na_2CO_3, by treating the crude salt with NH_3 carbamate in substantially anhyd. liquid NH_3, converting the resulting K and Na carbamates into the bicarbonates by treatment with water, sepg. the bicarbonates from each other and from assocd. impurities (suitably by known methods) and converting the bicarbonates into carbonates.

Concentrating phosphate-bearing material such as phosphate rock. WM. TROTTER and ELTOFT W. WILKINSON (to Minerals Separation North American Corp.). U. S. 1,795,100, March 3. The material is deslimed and then agitated and aerated in the form of a pulp with oil such as pine oil and a compd. such as Na oleate adapted to control selective oiling of the phosphate so as to effect froth flotation concn.

Purifying graphite. E. RABETRANO. Brit. 337,738, Nov. 9, 1928. Graphite in minerals of low C content is sepd. from materials such as silica, silicates or Fe oxides by fractional pptn. in a liquid contg. a colloid (such as water with an addn. of dextrin, alumina, saponin, gelatin or K silicate), with subsequent treatment of the graphite by electroösmotic action in a vessel in which the settlement of all suspended particles is retarded either mechanically (as by an agitating propeller with upward thrust) or by the presence of a colloid or by both methods. App. and various details of procedure are described.

Gold and silver solutions. A. MOZER. Brit. 338,383, Jan. 7, 1929. Solns. of Au and Ag, suitable for use in refining the metals electrolytically, for treating ores or for electrolytic or other gilding and silvering processes, are prepd. by treating the metal with a soln. of I in salts such as alkali or alk. earth metal iodides, sulfites or thiosulfates forming complex compds. with Au and Ag iodides. Chloride or bromides also may be added, and in some instances a cleansing agent such as Vienna lime may be added to form a pasty compn.

Hydrogen for use in catalytic synthesis. LUIGI CASALE. U. S. 1,793,677, Feb. 24. CO is produced from CO_2, O and a carbonaceous fuel contg. S, and the CO is subsequently converted by the action of steam in the presence of a catalyst to produce a mixt. of CO_2 and H and the CO_2 is finally removed. In this procedure the conversion of the CO_2 into CO is effected at a temp. (suitably 1000° or higher) high enough to effect the oxidation of any contained S into SO_2 and the latter is removed from the CO before its further treatment.

Sulfur. WERSCHEN-WEISSENFELSER BRAUNKOHLEN A.-G. Ger. 514,570, May 8, 1928. S is prepd. from gases contg. H_2S by leading it over a contact agent of large surface in which excess of SO_2 has been adsorbed. The SO_2 oxidizes the H_2S with liberation of S.

Sulfur from ammonium sulfide solutions. I. G. FARBENIND. A.-G. Brit. 337,395, July 29, 1929. Decompn. of NH_4 sulfide solns. at temps. above the m. p. of S is effected in the presence of adsorbent substances such as silica gel, $Al(OH)_3$, $Mg(OH)_2$, $Zn(OH)_2$, ZnS or other finely pulverized substances or raw cellulose fiber (suitably countercurrentwise with steam under 1.5 atm. pressure).

Active carbon. I. G. FARBENIND A.-G. (Ludwig Klebert, inventor). Ger. 517,428, Feb. 22, 1928. Subdivided wood is stirred for some time with a hot soln. of an activating agent, *e. g.*, $ZnCl_2$ or H_3PO_4, or boiled with the soln., and the mixt. is then dried and heated as usual. The wood may first be swollen with hot water. Cf. *C. A.* 25, 1045.

Activating carbon. I. G. FARBENIND A.-G. (Heinz Thienemann and Julius Drucker, inventors). Ger. 517,316, Mar. 12, 1926. In activating C by means of superheated steam or CO_2, an activating vessel having a wall permeable to gases is used and the activating agent is caused to diffuse therethrough. Thus, activation may be effected in a permeable chamotte tube, mounted concentrically in an iron tube, into which the activating agent is introduced.

Reactivation of activated carbon after use. C. H. LANDER, F. S. SINNATT, J. G. KING and W. E. BAKES. Brit. 337,348, July 23, 1929. After employment for absorption of S compds. such as H_2S and CS_2, reactivation is effected by heating and treatment with a basic substance such as NH_3, aniline, pyridine or quinoline (which may be used with superheated steam and a small proportion of air).

Carriers for catalysts. IMPERIAL CHEMICAL INDUSTRIES, LTD., F. A. F. CRAWFORD and W. A. P. CHALLENOR. Brit. 337,761, May 3, 1929. Catalysts for SO_2 production and other uses, such as Pt, V and Cr compds., are used on a carrier produced by incorporating "guhr" with a soln. of a sol. silicate, pptg. gelatinous silicic acid from the soln. as by the action of an acid or of $(NH_4)_2CO_3$ and drying to obtain a hard porous mass.

Pressed condensation products. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 142,936, Oct. 23, 1928. Filling material, aromatic amines, aldehydes and acid are intimately mixed to form a condensation product which is treated with an acid fixing agent. The product is dried and pressed. Thus, $PhNH_2$, CH_2O and HCl are mixed into an aq. suspension of asbestos. NaOH is added and the resulting mass dried, and pressure-molded to the desired shapes. Other examples are given.

Condensation products of fatty acids with polyalkylene-polyamines. I. G. FARBENIND. A.-G. Brit. 337,368, July 26, 1929. Fatty acids such as palmitic or oleic acids or their esters such as fatty oils or fats are condensed with diethylenetriamine, triethylenetetramine or a higher polyethylenepolyamine or polyalkylenepolyamine or mixts. of such compds. If not sol., the products may be alkylated and *they may be used as wetting, emulsifying, foaming and washing agents* and are stable in acid, neutral and alk. solns. Several examples are given.

Condensation products of urea and formaldehyde. MARTIN LUTHER, WILHELM PUNGS, ROBERT GRIESSBACH and CLAUS HEUCK (to I. G. Farbenind. A.-G.). U. S. 1,794,084, Feb. 24. SO_2 is used for hardening viscous completely condensed condensation products of urea and CH_2O.

Polymerized vinyl alcohol-aldehyde condensation products. I. G. FARBENIND. A.-G. Brit. 337,806, Aug. 6, 1929. Condensation products of rubber-like, plastic

and elastic or hard and brittle character are made by treating polymerized vinyl alcs. (which may be produced by saponification of polymerized vinyl esters) with aliphatic aldehydes such as formaldehyde or acetaldehyde, in the presence of acid catalysts such as HCl and H_2SO_4. Several examples with details of procedure are given, and products obtained may be formed into sheets, films, threads, etc.

Objects of albuminous material. INTERNATIONAL KUNSTHOORN INDUSTRIE N. V. Ger. 514,771, Aug. 3, 1929. Objects of insol. albuminous material of a casein character, especially animal casein, are formed by molding the objects from pure casein, subjecting them to a CH_2O bath without allowing them to harden throughout, drying the surface at 100° and molding to final form by cold pressure.

Impregnating compositions; adhesives. I. G. FARBENIND. A.-G. (Wilhelm Pungs, inventor). Ger. 517,279, Dec. 9, 1926. A mixt. of stearin pitch or like fatty pitch and vegetable or animal oils is heated with S or other sulfurizing agent, *e. g.*, S_2Cl_2, and before, during or after this treatment a product obtained by extg. tar with a partial solvent, *e. g.*, EtOH, is added to the mixt., heating being continued until the product has the desired consistency. Asphalt, tar, pitch, resins or fillers may be added to the mixt. or to the product. The animal or vegetable oils may be preliminarily oxidized or polymerized. Examples are given.

Fly and caterpillar adhesives. BERNHARD EIBES. (Viktor Scholz, inventor). Ger. 514,727, May 23, 1925. Adhesive material for catching flies and caterpillars consists of a 1–15% soln. of cellulose esters or celluloid waste products in castor oil. Odorants, coloring matter or filling agents may be added.

Pencils, crayons and chalks. A. PISCHEL and P. PISCHEL. Brit. 337,633, Nov. 27, 1929. A sulfonated oil such as Turkey-red oil is added to the mixt. used, before baking it.

Material for magnet cores, loading coils, etc. GENERAL ELEC. CO., LTD., and G. E. POLGREEN. Brit. 338,321, Oct. 24, 1929. Powd. magnetic material such as an alloy of about 80% Ni and 20% Fe (which may be prepd. as described in Brit. 327,865 (C. A. **24**, 5015)) is heated in a soln. formed of chromic anhydride and a halogen acid or halogen salt such as NaCl, preferably washed, and subjected to high pressure. Powd. refractory material such as ball clay, MgO or Al_2O_3 may be added to reduce the permeability of the core and increase the insulating of the core particles, and the cores after being formed under high pressure may be heat treated to develop their final permeability and hysteretic value (suitably at 500–600°). If desired, sol. matter may be left on the material until after the pressing and dissolved out after the heat treatment by a prolonged washing.

Wax emulsions. C. H. THOMPSON and W. J. MCGIVERN. Brit. 338,176, July 3, 1929. Emulsions, suitable for use in *polishing compns., soaps, for waterproofing* and in the manuf. of *lubricating greases*, are made by adding soap to melted montan or other non-saponifiable wax such as paraffin or ceresin, and other materials such as albumin, casein, glue or china clay or amino compds. such as triethanolamine may be added, as may also waterproofing agents such as varnish, linseed oil, shellac, rubber, silicates, etc.

Wetting agents. I. G. FARBENIND. A. G. Brit. 337,774, April 27, 1929. In a process generally similar to that described in Brit. 306,116 (*C. A.* **23**, 4082), no excess of high mol. org. acids is used for the condensation process, and the resulting acid amides or ester amides are converted into salts with acids (suitably either before or after treatment with alkylating or oxyalkylating agents). Numerous details and examples are given.

Water-soluble cleansing agents. JOHANN TENGLER. Swiss 142,691, June 1, 1929. Raw material capable of swelling is heated in an autoclave with caustic alkali, sulfonated oil or resin and hydrocarbons. Thus, starch is heated with NaOH, sulfonated castor oil and CCl_4. C_6H_6 may be added. The product is a good fat and grease solvent.

Detergent for removing tar, etc. J. H. WYLIE. Brit. 338,167, Aug. 14, 1929. A mixt. comprising benzene, turpentine, oil of citronella and olive oil is used for removing tar from, and cleansing, surfaces such as coachwork, fabrics, leather or metal surfaces.

Composition for removing grease and tar from lacquered surfaces. JOHN W. MEYER. U. S. 1,795,134, March 3. Spirits of camphor 1, "citronella" 1 and kerosene 12 parts are heated together, mixed with separately melted paraffin 2 parts, and the mixt. is cooled.

Composition for removing paint. N. C. W. PAINT & VARNISH REMOVER CO., LTD., and T. K. BONNAR. Brit. 337,944, Oct. 19, 1929. A paint remover is prepd. by cover-

ing quicklime with soft soap and water, stirring the mixt. and then successively adding Na_2CO_3, NH_4 carbonate and $Na_2S_2O_3$.

Removing paint from painted surfaces. J. H. GRAVELL. Brit. 337,461, Aug. 2, 1929. See U. S. 1,744,463 (*C. A.* **24**, 1478).

Cleaning agent for type metal. ERWIN HOFMANN. Ger. 514,726, Jan. 3, 1928. The prepn. consists of a reducing mixt. of wood charcoal, borax and earth alkali sulfide (except MgS). Molten colophony, NH_4Cl, NaOH and Na_2CO_3 may also be added.

Smoothing etched printing cylinders. CONZETT & HUBER. Swiss 141,344, June 25, 1929. Etched Cu cylinders are coated with an anti-etching prepn., which is wiped off so as to remain only in the depressions, and the cylinder is subjected to the action of an etching agent till the depressions disappear.

Removing the raised parts of etched copper printing cylinders. CONZETT & HUBER. Swiss 142,182, July 4, 1929. The cylinders are given a coating of a non-conductor of electricity which is mechanically wiped off, so that the raised parts are bared and the depressed parts covered. The cylinder is next placed as anode in a galvanic bath till the raised parts disappear. The cylinder is then removed and mechanically smoothed and polished.

Offset printing for copying documents, etc. W. L. LAWRENCE. Brit. 337,455, Aug 2, 1929. An original is prepd. with an aniline or other copying ink, an impression from this is taken onto a rubber or rubber-surfaced member previously treated with glycerol or the like and transfer to blank sheets is effected. The glycerol may be mixed with an aq. or alc. soap soln.

Waterproof coatings containing rubber latex. PAUL MEYERSBERG. Swiss 142,172, Aug. 15, 1928. A coating for materials contains natural or artificial rubber latex in a stable semi-pptd. thickened state. This state may be produced by addn. of weak org. acid. Alkali and saponifiable oils and fats may be present. In an example, the mixt. contains latex 65, concd. NaOH 1, pptd. chalk 20, castor oil 5, PhOH 0.5, colophony 4.5 and rapeseed oil 4%. Cf. *C. A.* **24**, 2906.

Waterproofing coating suitable for use on gas or oil pipes, etc. LESTER KIRSCHBRAUN (to Flintkote Co.). U. S. 1,794,522, March 3. A surface such as metal pipe to be protected from corrosion is treated with an aq. bitumen-pitch-type dispersion, the coating is allowed to dry and form a film, and over this is applied an aq. slurry of hydraulic cementitious material which is permitted to dry and form an outer protecting coating.

Wood effects on metal panels. HERMAN C. MILLER (to United Metal Products Co.). U. S. 1,794,528, March 3. A design is etched on a metal surface such as Cu or brass and the crevices and recesses in the etched surface are filled with a plastic mineral inlay such as a mixt. of whiting, graphite, varnish, lime, white lead, bronze and Al powder, water, Pb_3O_4 and oil and the inlay is baked, then ground flush with the normal surface of the metal, colored with a "chemical coloring" and the surface of the inlay is grained in imitation of wood grain.

Use of rubber and cork together in forming surfacings for power pulleys. CHARLES R. GRIFFITH. U. S. 1,793,927, Feb 24. Various details are described, involving the use of granular cork embedded in a lesser wt. of rubber.

Material for gramophone records. A. O. THOMAE. Brit. 337,437, July 1, 1929. A raw record material comprises gelatinized cellulose acetate with camphor or camphor substitute material, dried at 40–80°, the drying time being about 24 hrs. for each 0.1 mm. thickness. Various details of manuf. are described.

Material for sound records. H. T. BEANS (to Durium Products Corp.). Brit. 337,796, April 2, 1929. A core such as cardboard made from rag stock is coated with a resorcinolformaldehyde condensation product in which a plasticizer such as glycerol is incorporated to avoid brittleness. Various details of manuf. are described.

Material for playing-cards. HARRY L. POHS. U. S. 1,794,866, March 3. Cards are formed with a woven textile center fabric, an opaque phenolic condensation product on both sides of the fabric and in its interstices, and a layer of white phenolic condensation product over both sides of the opaque compn.

Dust bag material for suction cleaners. HOOVER CO. Brit. 338,253, Sept. 6, 1929. Material such as porous paper formed from pure manilla hemp fiber is strengthened by application of a resin and plasticizer such as a vinyl synthetic resin dissolved in ethylene dichloride or other solvent with dibutyl phthalate.

Preserving and improving gut for tennis rackets, etc., by treatment with synthetic resins. E. S. BARRALET. Brit. 338,223, Aug. 20, 1929. Either phenol-formaldehyde condensation products or those from glycerol and phthalic anhydride may be used. Various details and examples of treatment are given.

Fire extinguishers. I. G. FARBENIND. A.-G. (August Ruppert, inventor). Ger. 514,925, Sept. 21, 1928. The formation of $COCl_2$ in fire extinguishing by the aid of CCl_4 is diminished by adding NH_3 and aryl- or alkyl-phosphates to the extinguishing agent. Tricresylphosphate is mentioned in examples. Cf. *C. A.* **25**, 1348.

Apparatus for producing fire-extinguishing foam from water and foam-forming powdered materials. HANS BURMEISTER (to Pyrene-Minimax Corp.). U. S. 1,792,810, Feb. 17. Structural features.

Fire-extinguishing compositions. DAVID J. BLOCK (to Du-Gas Fire Extinguisher Corp.). U. S. 1,793,420, Feb. 17. See Brit. 319,372 (*C. A.* **24**, 2564).

Fire-extinguishing composition. LODIAS J. DUGAS (to Du-Gas Fire Extinguisher Corp.). U. S. 1,792,826, Feb. 17. $NaHCO_3$ is used with smaller quantities of $CaCl_2$, Na borate, NaCl and a filler such as infusorial earth, asbestos dust, silica or ash.

Fire-extinguishing system suitable for use with carbon dioxide. SWINGSPOUT MEASURE CO. Brit. 338,197, Aug. 15, 1929. Structural features.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

The employment of boric oxide in the glass industry. F. H. ZSCHACKE. *Glashütte* **59**, 846–9, *Chem. Zentr.* 1930, I, 879. B_2O_3 shortens the duration of fusion and clarification, improves the resistance against hydrolysis, the workability in the blowing process and the behavior with regard to expansion, strength and hardness. The quantity added should not be excessive. G. SCHWOCH

The structure of chilled glass. P. LAZAREV AND S. LIOSNYANSKAYA. *Compt. rend. acad. sci. U. R. S. S.* Ser. A, 1929, 107–8. *Chem. Zentr.* 1930, I, 630. The decrease in d. of chilled glass is studied from the surface to the center. When plates of chilled borax glass were ground so as to remove 58%, the sp. gr. of the remaining part of the glass fell from 2.2861 to 2.2810 and n fell from 1.5170 to 1.5158. When 90% by wt. was removed, n became 1.5151. The examn. in polarized light yielded characteristic interference figures, which give a good illustration of the decrease in hardness. No change in sp. gr. (2.284) was observed when the borax glass was cooled slowly. G. SCHWOCH

Optical properties of didymium glass. F. J. MOREL, H. S. LEIN AND D. E. SHARP. *Glass Ind.* **12**, 49–51 (1931).—This glass is composed of approx. 49.5% SiO_2, 14.0% K_2O, 6.0% Na_2O, 20.5% B_2O_3 and 10.0% impure com. didymium oxide. It has a high constringence, n of 1.53, and a sharp absorption band, but it does not show anomalous dispersion. H. F. KRIEGL

The silvering of glass. DONALD F. SHARP. *Glass Ind.* **11**, 273–6 (1930). Although a wide range of formulas may be used, each one is successful only when followed very closely. An ammoniacal Ag soln. is mixed with some reducing soln. such as sugar, glucose, Rochelle salts, etc. Improper cleaning of the glass and excess NH_3 in the Ag soln. are the most common causes of failure. After cleaning, the glass surface should be treated with dil. $SnCl_2$ soln. and rinsed with H_2O. H. F. KRIEGL

Crystal modes of the technical calcium sodium silicate devitrification and their interpretation. HANS JEBSEN-MARWEDEL. *Sprechsaal* **62**, 715–7, 735–9, 753–6, 773–6, 791–3; *Chem. Zentr.* 1930, I, 878–9. cf. *C. A.* **23**, 2063. The forces active in the crystallization process surpass the "crystallizing ability" by the amt. due to the inhibition on account of the internal friction. This more comprehensive term is called "crystallizing tendency." Many photographs of cristobalite and wollastonite crystals are given. The crystal modes are influenced by external factors, therefore they vary extensively. It is shown by means of crystals of an org. glass that the directed crystn. forces of the skeletons can be altered by external factors. In this case the arrangement of the crystal pattern assumes a medium position. The modes of devitrification make it possible to draw important conclusions with regard to errors in the manuf., which otherwise can be detected only by difficult and time consuming investigations. It was found that the cristobalite crystals in the glass are subject to an unexplained torsion force which is perhaps to be attributed to an unhomogeneous melt. The hexagonal star-shaped crystals hitherto described in the literature as tridymite are cristobalite crystals. The surroundings of the crystals are so strongly altered by the formation of crystals that this secondary glass segs. another phase. The wollastonite-cristobalite paragenesis thus found was followed and interpreted through all steps. Thus by crystn. the glass

is fractionated into residual glasses, each of which assumes a new position in the equil. diagram. G. SCHWOCH

Quinquennial review of the mineral production of India for the years 1924 to 1928. Clays. E. L. G. CLEGG. *Records Geol. Survey India* 64, 371–9(1930).—India produces china clay, fire clays, fuller's earth and clay for pottery, tile, etc. A. H. EMERY

The electrical dewatering of clay suspensions. CARL E. CURTIS. *J. Am. Ceram. Soc.* 14, 219–63(1931).—A history and full review are given of much previous work. Dewatering by electrophoresis is generally not more efficient than by using the filter-press, but on very fine-grained clays it is superior. Data and bibliographies are given, also a short biography of Count Schwerin. C. H. KERR

Manufacture of magnesia and magnesite brick. FRIEDRICH REINHART. *Tonind.-Ztg.* 55, 94–7(1931).—Recent German and foreign patents are reviewed. ROBERT FULTON FERGUSON

Effects of autoclave treatments on ceramic bodies and clays. H. H. HOLSCHER. *J. Am. Ceram. Soc.* 14, 207–18(1931). Porous ceramic bodies increase in vol. and wt. in autoclave treatment with steam pressure of 150 lb. per sq. in. The change is rapid at first but tapers off with increasing time. Typical American and English china clays also increase in vol., but ball clays do not. Prolonged drying treatments after the autoclave test also were studied. Data indicate that the vol. changes are not necessarily caused by rehydration of the clay within the body. Bodies contg. clay, feldspar and flint show a greater vol. increase than do the pure clay constituents. The compn. of the body is more important than the absorption in detg. the reaction to autoclave treatment. C. H. KERR

The ceramic industry of Ontario. ROBERT J. MONTGOMERY. *Ann. Rept. Ont. Dept. Mines* 39, Pt. IV, 196 pp.(1930). The compn. and properties of clay, and the manuf. of clay products are discussed, and a geological description of Ontario clays, and brief descriptions of all ceramic plants in Ontario are given. The latter produce chiefly heavy clay products, but lesser quantities of refractories, pottery, floor tile, elec. porcelain, glass and enameled Fe. ALDEN H. EMERY

Tests on ceramic materials. O. KALLAUNER. *1st Communications New Intern. Assoc. for Testing of Materials B*, 263–77(1930). A standard procedure is proposed comprising specifications for the prepn. of samples, mech. analysis, tests for fireproof qualities and tests on the prepd. material with regard to its applicability for prepn. as a plastic mass and on the test pieces made from such a mass. The latter tests comprise the detn. of the amt. of water necessary to work up the sample of earth into the plastic mass, the forming of the test pieces and the detn. of their properties after drying and burning. The following properties are detd.: behavior while working up to the plastic mass, shrinkage on drying, tendency to form blisters, bending strength, loss of wt. after burning, color, ring, shrinkage on burning, capacity to absorb water and sp. gr., E. J. C.

Aging and non-aging ceramic bodies. FELIX SINGER. *Keram. Rund.* 38, 167–71, 183–7, 216–22(1930). The failure of porcelain after repeated heating and cooling is due to differential thermal expansion either of (1) the constituents of the body itself, (2) the old constituents and the new, produced by gradual crystn. of the glass in the body, or (3) the body and the glaze. Disruption due to dissimilar expansibilities of glaze and body may be avoided by using glazes with high elastic limits and high strength. The most satisfactory porcelain for general purposes is one composed of a homogeneous, unstrained glass contg. many very fine mullite crystals. Steatite porcelain is superior to ordinary porcelain in resistance to aging and in all other important properties except thermal expansion, because it consists of a single constituent. H. INSLEY

The influence of time on the maturing temperature of whiteware bodies. I. F. H. NORTON AND F. B. HODGDON. *J. Am. Ceram. Soc.* 14, 177–91(1931).—Six typical com. bodies showed similar shrinkage and porosity curves for different firing times, but the longer the time the lower the curve was shifted on the temp. scale. In all cases the usual log. law relating temp. with rate of reaction applied. The const., however, was not the same for all bodies. II. CHARLES F. NORTON, JR. *Ibid* 192–206.—With samples that showed the same degree of maturity by phys. tests, the long-fired, low-temp. samples showed more quartz soln. as well as more mullite development than samples fired more quickly at higher temps. C. H. KERR

The origin of pin holes in cast ware. GERHARD BUDEWIG. *Keram. Rund.* 38, 215–6(1930).—An important cause of "pin holes" is the high viscosity of slips which does not permit the release of air bubbles introduced during blunging. A simple pipet viscometer is adequate for plant measurement of viscosity, a relative value for viscosity being obtained by the ratio of discharge time for the slip to the discharge time for pure

water. Increase in viscosity of casting slip is often due to the introduction of sol. electrolytes either from the raw materials themselves or from the mill water. H. I.

Burning of Oldenburg klinker [brick]. WERNER DOHM. *Ziegelwelt* **62**, 2–4 (1931).—A slow, prolonged, even firing at about Seger cone 6a is essential in securing proper sintering and density. Slow cooling is equally necessary to prevent brittleness. H. F. K.

Special refractories for electric-furnace linings. (a) Silica, corundum and Carborundum bricks. O. KUKLA. *Stahl. u. Eisen* **50**, 800–3(1930).—Expts. with a 7-ton-Héroult-Lindenburg elec. steel furnace show that Carborundum bricks behave well as a refractory in the roof of the furnace in a reducing atm. but are not as good as SiO_2 bricks for the body of the furnace in contact with the molten charge. In this position the Carborundum is rapidly burned at the surface of the bricks, thus causing rapid wear. Corundum bricks are unsatisfactory owing to their great tendency to spall. (b) **Sillimanite bricks.** F. SOMMER. *Ibid* 804.—Sillimanite bricks behave no better than good SiO_2 bricks in elec. steel furnaces and are 4 times as expensive. B. C. A.

Refractories for boiler furnaces. W. J. REES. *Brit. Clayworker* **39**, 431–7 (1931); cf. *C. A.* **24**, 5450.—The durability depends on 7 different factors, which are listed and discussed. R. A. HEINDL

Glass paving blocks (U. S. pat. 1,795,229) **20.**

Brands of Refractories: the brands of fire brick and other refractories manufactured in the United States and Canada, together with a list of their producers. 8th ed. Pittsburgh: American Refractories Institute. 70 pp.

Modern Refractory Practice. Pittsburgh: Harbison-Walker Refractories Co. 178 pp. Reviewed in *Blast Furnace & Steel Plant* **19**, 425(1931).

Glass. HERZOGENRATHER GLASWERKE BICHEROUX & CIE G. M. B. H. Ger. 514,609, Nov. 7, 1926. Rollers for rolling out molten glass are cooled by a liquid of b. p. higher than 100°.

Apparatus for feeding batch material to glass-melting furnaces. HAZEL ATLAS GLASS CO. Brit. 337,950, Oct. 24, 1929. Structural features.

Apparatus for feeding molten glass. BRITISH HARTFORD-FAIRMONT SYNDICATE LTD., and HARTFORD-EMPIRE CO. Brit. 338,089, Feb. 28, 1930. Structural features of app. having shear blades which are cooled and lubricated by use of moistened air.

Apparatus for delivering mold charges of molten glass. JOHN F. RULE (to Owens-Illinois Glass Co.). U. S. 1,792,932, Feb. 17.

Apparatus for delivering molten glass from furnaces. BALL BROS. CO. Brit. 337,988–9, Nov. 12, 1929. Structural features.

Feeding mold charges of viscous glass from a furnace. ALBERT R. BETHEL. U. S. 1,792,727, Feb. 17. App. is described.

Apparatus for forming hollow glassware such as bottles. AUGUST KADOW (to Owens-Illinois Glass Co.). U. S. 1,792,988, Feb. 17. Structural features.

Apparatus for glass-bottle manufacture. SOC. ANON. DES VERRERIES A BOUTEILLES DU NORD. Brit. 338,395, Sept. 24, 1929. Mech. features.

Forming glass rods or tubes. P. A. FAVRE. Brit. 337,540, Oct. 1, 1928. Mech. features and app. are described.

Sheet-glass-drawing apparatus. JOHN L. DRAKE (to Libby-Owens-Ford Glass Co.). U. S. 1,793,784, Feb. 24. Structural features.

Apparatus for drawing glass sheets. PAUL ESCOLE (to Ateliers de construction & fonderies de Jeumont (Anciens établissements Th. Haut)). U. S. 1,795,254, March 3. Structural features.

Removing thickened edges of glass sheets. PITTSBURGH PLATE GLASS CO. Brit. 338,045 and Brit. 338,778, Dec. 24, 1929. Various details of app. are described for heating the glass along lines parallel with and close to the edges for a distance corresponding to the length of a section to be severed from a continuously drawn glass sheet or ribbon, followed by removal of the section and application of a cooling device to the heated lines to cause the glass to crack along the lines.

Apparatus for plate-glass manufacture. JOHN H. FOX and WM. OWEN (to Pittsburgh Plate Glass Co.). U. S. 1,792,636, Feb. 17. Structural features.

Leer for annealing glass. HAROLD A. WADMAN (to Hartford-Empire Co.). U. S. 1,793,199, Feb. 17.

Glass-melting furnaces. HARTFORD-EMPIRE CO. Ger. 514,527, April 3, 1927. Details of construction.

Thermostatic control of temperatures in glass kilns, etc. PILKINGTON BROS., LTD., and P. M. HOGG. Brit. 337,803, Aug. 2, 1929. Variations in cond. of the material being heated are utilized for temp. regulation by an elec. system, various details of which are described.

Apparatus for "frosting" glass articles such as bulbs. JAMES BAILEY (to Corning Glass Works). U. S. 1,793,893, Feb. 24. Treating fluid is supplied under atm. pressure to a partially exhausted chamber, over openings in which the articles to be treated are supported. Various structural details are described.

Glass for use as a light filter. F. WEIDERT (to Deutsche Gasglühlicht-Auer-Ges.). Brit. 338,334, Dec. 15, 1928. Glass colored with neodymium oxide is used for light filters for accentuating color contrasts. Ce oxide may be added to absorb ultra-violet rays, or Cr oxide or Pr oxide may be used to make green more pronounced in appearance. The glass may be used for spectacle lenses or otherwise for filtering or special illuminating effects.

Glass permeable to ultra-violet rays. FRITZ WOLLNER, RICHARD WOLLNER and FERDINAND NIKOLAI. Austrian 120,674, Oct. 15, 1929; Fr. 691,805, Mar. 12, 1930. Glass is rendered permeable to ultra-violet rays by reducing the Fe_2O_3 present in the mixt. or in the melt to the metallic state. This may be effected by addn. of Al, Si, Mn, Zn or Ca.

Apparatus and procedure for uniting components of "safety glass" assemblies by heat and pressures. DUPONT VISCOLOID CO. Brit. 337,547, Oct. 27, 1928.

Drying clay ware, etc., in tunnel kilns. FRANK M. HARTFORD (to Harrop Ceramic Service Co.). U. S. 1,793,086, Feb. 17. Various details of app., humidity and temp. regulation are described.

Composite brick. EDWIN M. WYATT (to American Face Brick Research Corp.). U. S. 1,794,572, March 3. A building brick is formed with a burned facing section of argillaceous material and a concrete backing section formed of an aggregate of prepd. burned argillaceous particles and a cementitious binder, this binder serving also to unite the 2 sections.

Decorating bricks, flower pots, etc. A. F. BERRY. Brit. 338,147, Aug. 8, 1929. Articles of clay or composite material such as concrete are decorated by facing them with irregular fragments of stone, granite chippings or the like, suitably after initial application of a thin moist layer of portland cement, or by pressing into the surface of a green molded brick.

Apparatus for screening potters' slip and other viscous materials. MASCHINENFABRIK VORM G. DORST A. G. Brit. 337,371, Nov. 20, 1928. Structural features.

Tunnel drier for pottery. MÜLLER & PFEIFFER. Ger. 517,167, Jan. 20, 1927.

Magnetic separator for treating porcelain sludges, etc. MAGNET-WERK GES. EISENACH SPEZIALFABRIK FÜR ELEKTROMAGNETAPPARATE. Brit. 337,759, April 5, 1929. Structural features.

Refractory materials. METALLGES. A.-G. Brit. 337,605, Nov. 7, 1929. Mg silicate materials such as olivine, serpentine or talc contg. Fe are heated, without fusion, with substances rich in Mg, such as MgO or magnesite, in an oxidizing atm. for the conversion of the Fe present into Mg ferrite and of the free SiO_2 into Mg orthosilicate. Materials contg. Ni, Mn, Cr and Al may be similarly treated, and numerous details and examples are given.

Vitreous material suitable for casting or hot pressing in molds. PERCY B. CROSSLEY (to Mycalex (Parent) Co., Ltd.). U. S. 1,795,200, March 3. A mixt. formed of colloidal mica, colloidal asbestos, refractory ceramic material such as porcelain or glass infusible below 900°, and metallic flux material such as PbO and H_3BO_3 fusible below 900° is molded and vitrified. Cf. *C. A.* 25, 573.

Tile-glazing apparatus. GEORGE F. WILDE and BENNET K. ESKESEN. U. S. 1,792,788, Feb. 17. Structural features.

Muffle furnace for enameling sheet-iron ware. MANFRED WEISS STAHL- UND METALLWERKE A.-G. Swiss 141,563, May 21, 1929.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

The testing of cements by means of earth-moist and plastic mortars. J. P. LOEVENTHAL. *1st Communications New Intern. Assoc. for Testing of Materials B*, 204–9(1930).—In earlier comparative investigations carried out by the Danish state testing house the Swiss prism method and the common hammer method were used; in continuation,

a series of tests was made dealing with mortars of portland cement, aluminous cement and a Danish pozzuolana cement (Moler cement). The test pieces were made in compact molds and were of consistencies ranging from earth-moist to fluid. They were tested after 7 and 28 days. It was shown that at both times the strength curves of the portland and Moler cements were quite similar, although there was no proportionality. In contrast with this, mortars of aluminous cement of low water content showed an increase in strength between 7 and 28 days, while mortars of high water content showed a fall in strength. The various methods of testing are discussed. E. J. C.

Some properties of high-alumina cements from six countries. P. H. Bates. *1st Communications New Intern. Assoc. for Testing of Materials B*, 210–8(1930).—High-alumina cements (ciment fondu) manufd. in 6 different countries were examd. for their properties by chem., petrographic and phys. methods. The phys. characteristics were detd. by strengths in the form of 1:3 standard Ottawa sand tensile briquets and 2-inch compression cubes. Concrete was also tested in the form of 6 × 12 in. cylinders made from a 1:2:4 mix of gravel. The chem. analyses showed the cements were rather widely different from one another. The petrographic examn. showed that the alumina was largely present either as $CaO.Al_2O_3$ or as the unstable form of $5\ CaO\ 3Al_2O_3$. The wide variation in compn. and the difference in constitution did not result in as great a difference in phys. properties as would be expected. The effect of the heat generated during the setting of the cement and the effect of the amt. of mixing water used were also studied. Increased temps. during setting resulted in decreased strength. Increased amts. of mixing water resulted also in marked decrease in strength. E. J. C.

Hydraulic additions and trass-portland cement. S. I. Druzhinin. *1st Communications New Intern. Assoc. for Testing of Materials B*, 221–37(1930).—Volcanic tuff from the Crimea and diatomaceous earth from tested sources, when ground to the fineness of portland cement and added to portland cement clinker, give pozzuolana portland cement which, when used in hydraulic structures, is more resistant to sea water and acid water than is portland cement mortar. Its mech. strength after 2 months' hardening in water is equal to that of ordinary portland cement mortar without hydraulic addn., the same quantity of sand being used. The best methods for rapidly detg. the degree of activity of the hydraulic addn. are to est. the amt. of lime it absorbs and to compare the strength of mortars, with and without such addn., under the conditions afforded by accelerated hardening of the test pieces at 80°. The best method for detg. the optimum addn. of hydraulic material is the above-mentioned accelerated or thermal method. Pozzuolana-portland cement produces a more voluminous paste than ordinary portland for the same quantity of sand. E. J. C.

Fine grinding of cement. Ernst Rissel. *Zement* **19**, 1079–80(1930). The water permeability of concrete is more greatly affected by changes in the fineness of cement than is the compressive strength. The grading of the finer fractions of the cement also has a definite bearing on its ability to make concrete impervious. H. F. K.

Mill temperatures and the setting time of cements. K. Koyanagi. *Zement* **19**, 988–9(1930); cf. *C. A.* **24**, 5452.—Cements high in SO_3 were found to set rapidly under high mill temps. while those of low SO_3 content were not affected. H. F. Kriege

Portland cement materials in Arkansas. W. R. Spencer. Univ. Arkansas, *Eng. Expt. Sta. Bull.* No. **6**, 27 pp.(1929). E. H.

Investigation of portland cement and its constituents by means of vapor-pressure measurements. F. Krausz and G. Jörns. *Zement* **19**, 1054–5(1930).—The use of a micro-tensi-eudiometer is proposed to follow the formation of cryst. or colloidal phases in the hydration of cements. H. F. Kriege

Free lime in portland cement and soundness. G. Haegermann. *Zement* **19**, 982–4(1930).—Under a range of burning temps. of 1225–1475° the free lime in 12 cements was found to vary irregularly with temp. from 0.24 to 1.85%. In general, cements were sound in cold H_2O when they contained up to 4% free lime, while 1.2% was the upper limit when subjected to the boiling test. H. F. Kriege

Free lime, soundness and strength (of cement). A. Guttmann. *Zement* **19**, 1078(1930).—G.'s investigations confirm those of Haegermann (cf. preceding abstr.) in regard to the content of free lime and soundness in cements. Further G. found a definite increase in tensile strength with a decrease in the free CaO present in the cement. H. F. Kriege

Action of gypsum, swelling and hydration. F. Tippmann. *Zement* **19**, 1030–5, 1056–60, 1080–6, 1106–12(1930).—**The properties of gypsum, raw and in its various phases of dehydration, are discussed in relation to their effects on cement.** Numerous photomicrographs are given showing the cryst. products of the hydration and hardening stages of cements and other materials. H. F. Kriege

Quicker tests of cement and concrete. H. KREÜGER. *1st Communications New Intern. Assoc. for Testing of Materials B*, 114 8(1930).—Preliminary tests made to investigate whether it might be possible to decide quickly (in 1 or 2 days instead of 28 days) whether a cement is fit for delivery showed that there probably is a fairly good concordance between the normal crushing strength of cubes after 28 days' combined air- and water-curing and after a few hours' steam-hardening. The method may be of some use also for quicker testing of concrete, but has not yet been satisfactorily developed. E. J. C.

Compression, tension and bending tests, cement and concrete. A. T. GOLDBECK. *1st Communications New Intern. Assoc. for Testing of Materials B*, 61–6(1930). E. J. C.

Cement, concrete and reënforced concrete—laboratory tests and control and practice on the building site. A. HASCH. *1st Communications New Intern. Assoc. for Testing of Materials B*, 94–9(1930) (in German); cf. *C. A.* **24**, 3874.—An attempt is made to consider briefly, from the present-day standpoint, the relative merits of ordinary and high-strength mortars and concrete, and tests to which these materials should be subjected in the lab. and on the building site. The essential point is organization of control tests on the site, combined with chem. lab. tests, because samples taken before building is started are of no value. The theory of probability is applied to results of static tests. E. M. SYMMES

Resistance of concrete pipes to corrosion by water. J. O. ROOS. *1st Communications New Intern. Assoc. for Testing of Materials B*, 144–8(1930).—In Sweden, decompn. of concrete pipes is due mostly to the external action of H_2O percolating through the pipe wall and extg. lime from the cement. Pure H_2O has a high disintegrating effect; a water contg. 0.30–80 mg. per l. of CO_2 increases and lime hardness decreases the corrosion. To be durable, concrete pipes must be impermeable to water. E. M. S.

Slag concrete. I. BENTKOVSKII. *1st Communications New Intern. Assoc. for Testing of Materials B*, 238–43(1930) (in German). Tests were made by the Institute of Metals, Leningrad, to use a particular slag for concrete. E. M. SYMMES

Resistance of concrete to chemical attack. K. MANDL. *1st Communications New Intern. Assoc. for Testing of Materials B*, 149–56(1930).—In Austria the deterioration of concrete due to injurious influences is relatively slight. The most prominent instance is the destruction of a pillar of a new dwelling house in Vienna, which was definitely found to be due to the action of gypsum. It is especially noteworthy that this damage was not due to sulfate contg. ground water, but to surface water that had percolated through the slag-contg. bottom layer, from which it dissolved the sulfate, and then was forced to pass through the concrete pillar, because the slag deposit was laid on material impermeable to water. Several cases of deterioration of the sewer system of Vienna by sulfate-contg. water are also reported. Results of an investigation into the action of nitrites on concrete have been published in part, but it is not yet possible to draw conclusions from this work. E. J. C.

The compactness of concrete and its resistance to chemical action. A. POULSEN. *1st Communications New Intern. Assoc. for Testing of Materials B*, 157–61(1930).—Even the best concrete is destroyed by the reaction of its free lime with the $MgSO_4$ contained in sea water. Rich mixts. soon show cracks of their own accord. The application of a protective coating to large masses of concrete employed in marine work is, of course, impossible. To neutralize the excess lime it is necessary to add to the cement pozzuolana contg. in sufficient quantity the necessary hydraulic constituents (*e. g.*, SiO_2 sol. in alkalies). The cement with hydraulic admixts. thus obtained should be submitted to lab. tests. In Denmark, the Danish diatomaceous earth, Mo Ler, which contains about 60% of sol. SiO_2, has been used with considerable success for the past 20 years. E. J. C.

Evaluation of shrinkage data on light-weight concrete. A. HUMMEL. *Zement* **19**, 1062–6(1930). - While light-weight concretes have greater vol. changes than do concretes contg. the usual mineral aggregates over the same humidity ranges, these vol. fluctuations need not imply greater danger of crack formation. H. F. KRIEGE

Method of disintegrating hardened concrete for the determination of the original ingredients. R. LOMAN. *1st Communications New Intern. Assoc. for Testing of Materials B*, 167–79(1930).—It is possible to disintegrate the concrete satisfactorily without smashing up the aggregate by heating for a time to 800–900° and cooling by suddenly quenching in water. The aggregate is sepd. from the cement and can be sieved; it is almost completely recovered, but has generally become a little finer as a result of the ignition and embrittlement on quenching. This increase in fineness is revealed by the sieving. The proportion of cement can be estd. by various methods. Expt. has proved, however, that the most rapid method and the one that gives the most reliable results

consists in heating to 800–900° (which removes combined water and CO_2) and then cooling in a space free from water vapor and CO_2. The wt. obtained is that of the original cement less its loss on ignition. The method is of sufficient accuracy for technical work. E. J. C.

Deterioration of concrete in hydraulic structures. A. EKWALL. *1st Communications New Intern. Assoc. for Testing of Materials B*, 162–6(1930); cf. *C. A.* **23**, 5558.—Inspections of hydraulic structures in Sweden 10 years ago showed some defects in the concrete and continued observations proved that the concrete in some cases was subject to an increasing deterioration, apparently due to the quality of the concrete materials, to the methods of making concrete or to the conditions to which the concrete was exposed. The aim of these investigations was to ascertain the causes of such increasing deterioration. It had been observed that deterioration occurred only in structures exposed to water on one side and was caused by the soly. of the lime and the decompn. of other chem. combinations in the hydrated cement. Particular attention was therefore directed to the soly. of the cement and the aggressiveness of the water. Practical expts. were made at the same time with concrete slabs exposed to low water pressure during several years. It was proved that Swedish natural waters need not be considered aggressive in this respect. The importance of using sand relatively free from org. substances was impressively established. Leaner mixts. than 1:4.5 should not be used for concrete exposed to water pressure from one side. Replacing cement by an admixt. of 10% lime or 5% $CaCl_2$ improved the watertightness, while 25% trass or slate powder gave practically no improvement. E. J. C.

Natural and artificial stone—mineralogical and petrographic properties. Methods of testing. L. FINCKH. *1st Communications New Intern. Assoc. for Testing of Material B*, 21–4(1930). E. J. C.

Coöperation of the mineralogist and petrographer in judging natural and artificial building stone and road stone. P. NIGGLI. *1st Communications New Intern. Assoc. for Testing of Materials B*, 1–9(1930).—The mineralogist should conduct the sampling of the material, so as to provide a typical sample for investigation, and thoroughly describe it from the mineralogical standpoint as to its chem. nature, durability, structure and texture. After the tech. tests, he should evaluate the behavior of the material mineralogically and relate it with the properties found. The mineralogical-petrographic methods can be conducted with min. quantities of material and are therefore particularly suited for control expts. It is thus important to elucidate experimentally the relation between tech. behavior and the nature of the material, so that tech. tests can be more and more replaced by mineralogical examn. E. J. C.

The application of mineralogical and petrographic knowledge in the testing of nonmetallic inorganic materials. R. GRENGG. *1st Communications New Intern. Assoc. Testing of Materials B*, 13–20(1930). E. J. C.

Structure of weather-resisting rocks (VAN DER VEEN) **8.** Siliceous CaO compound [for use in cold cement industry] (Ger. pat. 514,742) **18.** Decorating bricks, flower pots etc. (Brit. pat. 338,147) **19.** Rubber compositions [for expansion joints, wall and road coverings, etc.] (Brit. pat. 338,247) **30.** Producing carbide-forming metals [with cement as a by-product] (U. S. pat. 1,794,401) **4.** Forming sheet insulating material such as wallboard (U. S. pat. 1,794,433) **13.**

Concrete Year Book, 1931. A Handbook, Directory and Catalogue of Concrete, 8th year. Edited by O. FABER AND H. L. CHILDE. London: Concrete Publications, Ltd. 3s. 6d., net.

HERTEL, PAUL: **Einfluss der Verwendung von Edelzuschlag auf die Güte und die Kosten von Beton.** Charlottenburg: Zementverlag. 64 pp. M. 2.

Cement. PERRIN & TUSCHER. Swiss 141,823, April 25, 1929. The cement contains essentially blast-furnace slag, lime and bauxite. Gypsum may also be added.

Portland cement. ANDREW LUNDTEIGEN and GUY O. GARDNER (to Ash Grove Lime & Portland Cement Co.). U. S. 1,794,526, March 3. A quick-hardening cement is made by adding, to a clinker formed from argillaceous and calcareous materials, gypsum and a mixt. of $CaCl_2$ and NaCl sufficient to act as accelerators for hardening the final product, and grinding the aggregate thus formed with a lubricant such as Al stearate so that at least 78% passes a 200-mesh screen.

Chlorine-treated cement. HANS M. OLSON. U. S. 1,792,755, Feb. 17. Cl gas is directly mixed with hydraulic cement during its grinding in order to facilitate obtainment of rapid set and early strength.

Apparatus for testing cement, etc. W. D. WILLIAMS. Brit. 337,786, Aug. 2, 1929. Various details of app. are described suitable for use in boiling substances for testing as in the Le Chatelier test for cement, boiling cement pats, testing porosity or permeability of cement disks, etc.

Cement-coloring and hardening composition. MAXIMILIAN TOCH (to Standard Varnish Works). U. S. 1,793,143, Feb. 17. A material for coloring and hardening portland cement comprises a dry mixt. including a coloring material resistant to portland cement such as Fe oxide, Cr oxide, MnO_2 or lampblack together with $CaCl_2$ and a colloidally pptd. material such as Al silicate, $BaSO_4$ or Ca aluminate.

Feeding cement material to kilns. POUL T. LINDHARD (to F. L. Smidth & Co.). U. S. 1,793,499, Feb. 24. Slurry is delivered to a kiln as an atomized spray cone, dust is sepd. from the kiln gases and this dust is returned to the kiln at a point where the cone of atomized slurry substantially fills the diam. of the kiln. App. is described.

Rotary kiln (with slack chain groups in its interior) suitable for burning cement-forming slurry. JOHAN S. FASTING (to F. L. Smidth & Co.). U. S. 1,793,471, Feb. 24.

Rotary kiln suitable for cement manufacture, etc. HAAVARD KRONSTAD (to Bessemer Cement Corp.). U. S. 1,793,408, Feb. 17.

Concretes and mortars. J. W. BATTERSBY. Brit. 338,242, Aug. 27, 1929. A waterproof product is prepd. by adding a powder of colloidally readily sol. water-contg. alkali silicate 2–5% to portland cement or lime concrete or mortar prior to mixing with water (preferably to the cement clinker before grinding it). The initial set period may be controlled by varying the amt. of water in the silicate (which may be 10–30%). For some purposes such as sealing porous places in floors a much larger proportion of silicate powder may be added.

Apparatus for molding concrete blocks. FAVRE & CIE. ZELLENBETONFABRIK WALLISELLEN. Swiss 142,088, May 15, 1929.

Bituminous paving materials. EDWIN C. WALLACE. U. S. 1,793,345, Feb. 17. Bituminous paving compns. workable at atm. temp. are prepd. by coating heated particles of mineral matter with heated bituminous cement in sufficient quantity to cause agglomeration when the mass becomes chilled and, before chilling, adding to the mass cold, non coherent, non hydroscopic material comprising mineral particles coated with bituminous cement, proportioned to render the entire mass granular and friable but capable of consolidation by the application of pressure alone. Cf. *C. A.* **25**, 793.

Bituminous compositions for roads, etc. F. A. HILL. Brit. 338,206, Aug. 16, 1929. A cold-lay compn. suitable for surfacing roads, canal beds, etc. and which is stable when stored in hermetic containers) is made by mixing at a temp. of 100° or higher, asphalt, bitumen, tar, pitch or asphaltic petroleum residues with a fuel oil or petroleum product from which all the lighter portions including the illuminating oils have been distd. The material may be used in the proportions of 35–55 and 65–45%, resp.

Bituminous coating compositions. I. G. FARBENIND. A.-G. Brit. 337,521, Sept. 4, 1929. Products for covering roads, lining vessels, etc., are made by incorporating bituminous materials such as natural or artificial bitumens, mineral or brown coal tars or their distn. products with synthetic polymerization products of diolefins such as those of butadienes, which incorporation may be effected in the presence of a diluent such as benzene or cyclohexanol, and if desired with emulsification with water effected by a suitable emulsifying agent. Various details and examples are given.

Bituminous pavements. JOHN RADCLIFFE (to Colprovia, Ltd.) U. S. reissue 17,985, March 3. Reissue of original pat. No. 1,655,240 (*C. A.* **22**, 1026).

Road-surfacing materials. I. G. FARBENIND. A.-G. Brit. 337,928, Oct. 12, 1928. Slippery deposits on roads are removed by use of org. solvents or their aq. solns. or emulsions to dissolve the oils and fats or swell the rubber in the deposits, followed by brushing and washing with water. Various examples of solvents and emulsions are given.

Rubber-surfaced paving blocks. EDWIN C. WALLACE. U. S. 1,794,220, Feb. 24. Structural features.

Glass paving blocks. PIERRE NOEL. U. S. 1,795,229, March 3. Structural features.

Material suitable for expansion joints. ALBERT C. FISCHER (to Philip Carey Mfg. Co.). U. S. 1,793,439, Feb. 17. Sheets are formed with a waterproof ductile binder such as blown asphalt having mixed with it flat and relatively thin strips of fibrous roofing scrap. Cf. *C. A.* **24**, 2574, 4608.

Artificial stone. JERRE HAGGARD. U. S. 1,793,172, Feb. 17. A vesicular aggregate such as cinders or basalt is used with granulated gypsite and hydrated lime.

Artificial marble residues. ALEXANDER STAEGE. Ger. 514,710, Nov. 19, 1927. The residues from the manuf. of artificial marble contg. MgO cement are ground and all sol. constituents removed by lixiviation with water. The residue is then used as flux for portland cement mortar.

Porous building material. ERIK C. BAYER. U. S. 1,794,272, Feb. 24. A tenaceous foam which may be formed from resin soap, gelatin and water is mixed with mortar and the material is formed and cured under high steam pressure. Cf. *C. A.* **24**, 4134.

Waterproof sheet material for building construction. E. RUDIN and H. KOLLBRUNNER. Brit. 338,403, Dec. 13, 1928. Corrugated cardboard layers are superposed with the corrugations of adjacent layers at right angles to each other, fastened together by threads or wires or the like without adhesive, dried at 60–70°, impregnated with coal-tar pitch or the like and pressed.

Fireproofing binder for use with fibrous material. CHARLES H. BROWN. U. S. 1,793,357, Feb. 17. A compn. suitable for use with fiber in making wall board, etc., consists solely of NH_4 phosphate, H_3BO_3, dextrin and water, with a greater proportion of NH_4 phosphate than of H_3BO_3 and a greater proportion of dextrin than of NH_4 phosphate.

Roofing material. RALPH E. DRAKE (to Anaconda Sales Co.). U. S. 1,794,449, March 3. Crushed and graded elec cond material such as crushed coke substantially free from dust is applied as a layer to the surface of material such as asphalted roofing felt so as to form an irregular surface, and a cond powder such as graphite is applied over this surface so as to fill interstices between the granules, and a metal such as Cu is applied as an electrodeposited layer over the cond material.

Plaster. V. LEFEBURE. Brit. 337,926, Oct. 10, 1929. Anhydrite is mixed with plaster of Paris or "any standard plaster" such as Keenes cement, and the anhydrite may be "accelerated" as described in Brit. 236,695 (*C. A.* **20**, 1310) and Brit. 317,672 (*C. A.* **24**, 2267), and by varying the relative proportions of the ingredients; the setting time may be varied upward from an almost instantaneous set as desired. Various details and examples are given.

Plaster. FOSTER D. SNELL. U. S. 1,792,661, Feb. 17. A plaster of "retarded suction" comprises a calcareous binder such as slaked lime, a filler such as sand, together with water, and a "minimal" quantity of dispersed lime soap present to the extent of only about 0.16 lb. per cu. yard.

Plasterboard. HAROLD L. LEVIN (to Flintkote Co.). U. S. 1,793,810, Feb. 24. See Brit. 319,213 (*C. A.* **24**, 2573).

Kiln suitable for drying lumber. ALBERT ARMSTRONG. U. S. 1,793,892, Feb. 24.

Preserving wood. I. G. FARBENIND. A.-G. (Wilhelm Bonrath, Wilhelm Schepss and Karl Taube, inventors). Ger. 517,207, Feb. 10, 1928. The wood is treated with compds. in which Hg is linked by at least one of its valencies to an unsubstituted or neutrally substituted hydrocarbon radical. Phenylmercuric acetate and ethylmercuric bromide are suitable. The compds. may be used in soln. in an org. solvent, or in aq. emulsion or soln., and their solv. in water may be increased by addn. of alk. compds. Examples are given. Cf. *C. A.* **25**, 1056.

Treating wood. ADOLF KISSNER, JR. Ger. 514,980, Nov. 24, 1929. Wood surfaces are protected by an elastic waterproof layer of bitumen admixed with fine wood meal.

The use of sugar for motor fuel. K. ŠANDERA AND J. ZERMAN. *Z. Zuckerind. Čechoslovak. Rep.* **55**, 172–4 (1930). See *C. A.* **25**, 576.
J. F. LEETE

Tests on agglomeration of combustibles. M. G. LEVI, C. PADOVANI AND F. CARDIA. *Atti III congresso naz. chim. pura applicata* **1930**, 753–66.—Briquetting tests were made on lignite, anthracite, semicoke, peat and mixts. of these with sulfite tar, mineral oil, linseed oil and mixts. of these. Resistance to fracture and atmospheric effects were detd.
E. M. SYMMES

Determination of moisture in combustibles. C. PADOVANI AND C. SINIRAMED.

Atti III congresso naz. chim. pura applicata 1930, 778–81.—Combustibles may oxidize during the detn. of moisture (*Compt. rend. 7 congresso chim. ind.* Oct., 1927). All coals, heated to 60–70° in a current of N_2 free from O_2, evolve small quantities of CO_2. A method was developed to det. simultaneously the loss of wt. of the coal by heating at 100° in a current of N_2 and increase in wt. of a $CaCl_2$ tube. Loss of wt. of the coal is greater than increase in wt. of the $CaCl_2$ tube. E. M. SYMMES

Incomplete combustion: its importance, recognition and prevention. E. W. B. DUNNING. *Gas J.* 193, 271 6; *Gas World* 94, 127–30(1931).—A review is given of the fundamental principles of combustion together with the physiol. effects of the products of complete and incomplete combustion. The importance of CO in incomplete combustion is emphasized. It is the only gas that can be present in sufficient concn. to be dangerous in the flue products from gas-consuming appliances. The combustion characteristics of various types of gas appliances are reviewed and the amt. of CO to be expected is shown to be below any figure at which adverse physiol. effects can occur. The products of combustion of town gas can be and should be harmless. When this is not the case the cause can be traced to the various factors in the design of the gas appliances. The degree of incompleteness of combustion is detd. by the analysis of the flue gases for CO. The estn. of the products of incomplete combustion offers some difficulty because of the small concn. in which they are present and special methods must be used. The CuCl method is not suitable for detg. CO. The preferred method, which is very sensitive, is the oxidation of CO with I_2O_5 according to the following equation $I_2O_5 + 5\ CO = I_2 + 5\ CO_2$. A train of app. for this method is described and illustrated. An accuracy of 2–3 parts of CO per million of flue gases can be obtained. F. H. BERGEIM

The problem of lignite in Italy. ALDO REGÉ. *Chim. ind. agr. biol.* 7, 17–27 (1931).—Lignite was found in small quantities in every Italian Province, but mostly in Tuscany. The Valdarno lignite contains: moisture 51.8, volatile matter 25.35, ash 6.60, fixed C 15.25%, and has a heating value of 7663 cal (on dry basis). The gas obtained by distn. has a heating value of 5592–6192 cal; the coke is of bad quality, but a very good coke is obtained by mixing the lignite with 25–30% of ordinary coal. The Piedmont lignite has: moisture 10–13, volatile matter 30–36, fixed C 34–45, ash 12–13%. The xyloid lignite from Spoleto has: moisture 35–45, volatile matter 30–45, ash 8–18, fixed C 27–38%, heating value 3–4000 cal and the gas obtained by distn. contains: CO_2 12–14, O_2 0.2–0.7, H_2 25–29, CO 11–14, CH_4 2–5, N 34–40% and has a heating value of 1050–1350 cal. G. A. BRAVO

The torbanites of South Africa. F. H. CUNNINGHAM CRAIG. *J. Inst. Petroleum Tech* 16, 620–5(1930).—See *C. A.* 24, 2860. EMMA E. CRANDAL

Some modern ideas on coal. F. V. TIDESWELL. *Colliery Guardian* 140, 1651–4, 1744–6, 1845–6(1930). A detailed summation is given of the present state of our knowledge of the structure and compn. of coal. E. M. SYMMES

The classification of Roumanian coals. I. BLUM. *Bul. chim. soc. română stiinte* 31, No. 4–6, 3–11(1931).—The basis for the classification of coals is clarified. The geologic age is not a sufficient criterion for the purpose. Physico-chem. and petrographic characteristics of the coal must also be considered. The decisive factors in detg. the chem. age of coal are (1) elementary compn., (2) behavior on distn. and (3) resistance to action of certain solvents. The later coals contain less C and more O, have a lower calorific value, and give off more gas (largely CO_2) and at a lower temp. than the earlier ones. In consideration of these ideas Lupeni coal, usually considered a superior lignite, should be classified as bituminous. CHANNING WILSON

The rôle of the components of Roumanian fossil coals in the composition of the gas distilled from them up to 500°. I. BLUM. *Bul. chim. soc. română stiinte* 31, No. 4–6, 13–9(1931).—Four Roumanian coals and lignites were extd. with solvents, and the residues from each extn. submitted to distn. Bitumen was removed from the original coal by extn. with a benzene-alc. mixt., lignin by extn. with H_2SO_3 in an autoclave, and humic acids with NH_3 soln. at 90°. No cellulose was found in the coals examd. The residues richer in humic acids and lignin gave more gas on distn. Unsatd. hydrocarbons were less in residues after extn. of bitumen. CO and CO_2 were found in larger quantities in gas obtained from residues rich in lignin, and especially humic acids. The gas from the carbonaceous residues after all three extns. contained a larger percentage of CH_4. CHANNING WILSON

The coal industry of South Africa. T. COULTER. *J. Chem. Met. Mining Soc. S. Africa* 30, 348(1930); cf. *C. A.* 24, 4374, 5133; 25, 576.—Discussion. A. H. E.

Washability studies of the Black Creek bed at the Bradford Mine, Dixiana, Ala. B. M. BIRD, B. W. GANDRUD AND C. B. BARMORE. Bur. Mines, *Rept. of Investigations*

3083, 12 pp.(1931).—The prepn. of a washed coal contg. less than 2% ash should be practicable with a comparatively simple washing system. The coal contains a large proportion of fine sizes due to friability. There are only small quantities of flaky impurities. The coarse and fine sizes should be separately washed. A. H. E.

A contribution to the coal-dust problem. I. Mathematical treatment of the free fall of dust particles. II. Deposition of dust particles from a horizontal gas stream. III. Centrifugal separation of dust from gases. Fr. Prockat. *Glasers Ann.* **106**, 73–9, 93–7, 151–4; **107**, 38–45, 47–54(1930).—A formula for free fall of dust particles is derived, which is superior to that of Stokes, and agrees with the data within 10%. Mathematical formulas are derived for horizontal settling chambers and centrifugal separators, which are in agreement with data from exptl. equipment. L. W. T. C.

Determination of sulfur in coal, gas and purifying material. J. H. Steinkamp *Gas Age-Record* **67**, 53–4(1931).—The Parr $KClO_4$ method for coal is briefly described. A method for gas, of burning the gas, oxidizing the SO_2 in 3% soln. of H_2O_2 and titrating with 0.1 *N* KOH is described. For S in purifying material, the material is extd with CS_2, tarry matter being removed by passage of the CS_2 through a tube filled with activated coal. The CS_2 is evapd. in a crystg. dish which is placed in a drying oven at 50° for one hr., leaving pure S, which is weighed. Leslie B. Bragg

The assay of coal for gas manufacture. J. G. King. *Gas Eng.* **48**, 75–7(1931); cf. *C. A.* **24**, 944.—A modification of the Gray-King Method (*C. A.* **23**, 5026) for the assay of coal is described, making it suitable for application to coals used in gas manuf The volatile products of carbonization are passed through a cracking zone in which the temp. is controllable. The probable yields of products are calcd. from the assay yields by suitable factors obtained by comparing the yields obtained from a certain no. of typical coals. The correlation of assay and plant yields is more difficult with vertical retorts than horizontal retorts, although it is satisfactory in both cases

Channing Wilson

Midwest coals in gas-producer practice. O. L. Scales. *Blast Furnace Steel Plant* **19**, 252–4(1931).—While there is no advantage in the use of midwestern coals from the standpoints of operation, of more satisfactory railroad service or of improvement in the product, good midwestern coal is considered, at present prices, more economical for gas producers than eastern coal. H. C. Parish

Variations in the evolution of gases on preheating coals having reached different stages of evolution. M. Legrave. *Chimie & industrie* **25**, 18–21(1931); cf *C. A.* **24**, 710.—Twelve coals (all but 1 from the Liège coal fields), selected so as to have comparable contents of vitrain and durain, were treated under exactly the same conditions by the same operator, as follows: volatile matter was detd. as usual; a 2nd portion was heated 30 min. at 400°, allowed to cool, and volatile matter was then detd. in the usual way. Similar tests were carried out on 4 samples of vitrain which were sep. from the coals and which contained 10.2%, 12, 15 and 20% volatile matter, resp. Two samples of fusain, with 8.5 and 17% volatile matter, resp., both gave approx. 10% volatile after preheating. The facts that the curve for the whole coal crosses the volatile-content axis at about 15–8% volatile matter, which is approx. the crit. volatile content sepg. coking from non-coking coals, that the general trend of the vitrain curve is similar to that of the whole coal but the total evolution of gases is considerably smaller, and that the preheating treatment completely destroys the coking properties of coal suggest that a study of the chem changes undergone by vitrain carried out on carefully selected coals representing the various stages of the evolution of coal might yield valuable information on its role in the coking of coal. A. Papineau-Couture

Protection of working people and of the neighborhood in the firing of pulverized coal. W. Weitfeldt. *Zentr. Gewerbehyg. Unfallverhütung* **17**, 142–7(1930). Four dangers exist: dust, poisonous gases, explosions and fire. Inhalation of dust is less dangerous than CO and other gases, which occur from excessive pressure due to blockage. Fat coal is the most dangerous from an explosion standpoint. Coal of 50% ash is particularly free from risk. Conditions causing fire and explosion are described

George R. Greenbank

An investigation into the health of employees in gas-making plants. F. R. Kerr Commonwealth of Australia Dept. Health, *Bull.* No. 7; *Bull. Hyg.* **6**, 27(1931). Three hundred and seventy workers in gas plants were subjected to radiant heat, fumes and coal dust. They were divided into 3 groups according to Schneider's fatigue test, pulse rate and blood pressure. Only 105 fell into the last group which gave the poorest test. There seemed to be no ill effects of the work. Eight cases showed 5% or more carbohemoglobin; 1 case showed 15%, but no increase in red blood cells. K. recom-

mends appliances for administering O and CO_2 mixts. in acute cases of gassing.
GEORGE R. GREENBANK

Purification of town gas by means of oxide of iron. J. DREVERMAN. *Gas J.* **193**, 97–100(1931).—The principal factors governing the use of iron oxide for the purification of gas are (1) the activity of the oxide for the absorption of H_2S, (2) the phys. state of the oxide, (3) the concn. of the H_2S in the gas, (4) the velocity of the gas, (5) the time factor for chem. reaction and (6) the design and economical no. of boxes. In practice iron oxide is used either in the form of a slurry by mixing with water and circulating through tower scrubbers or as a relatively dry spongy mass standing on grids in covered purifier boxes through which the gas is passed. The dry method is the most commonly used. The suitability of various forms of iron oxide is discussed. When the dry method is used the oxide is usually mixed with sawdust, shavings, grain husks, cut-up straw, tan bark or old oxide. Details are given on the operation of an iron oxide purifier at Mortlake (Australia).
F. H. BERGEIM

The utilization of butane-air gas in domestic appliances. G. L. BRENNAN AND L. H. WRIGHT. *Gas Age-Record* **67**, 37–41, 60(1931).
LESLIE B. BRAGG

The tetralin process (for avoiding naphthalene stoppages in gas mains). GEORG WEISSBERGER. *Gas u. Wasserfach* **74**, 154–6(1931); cf. *C. A.* **24**, 5464, 5978.—Two methods for introducing tetralin into gas mains are given: (1) by elec. heating to vaporize the tetralin and (2) cold atomization. These methods are illustrated and discussed. The formula for the amt. of tetralin to be vaporized into the main per day is $x = 5\ m\ (A + 8)/100{,}000$, where x is the kg. of tetralin per day, m is the vol. of gas in cu. m. per day, and A is the naphthalene content of the gas in g. per 100 cu. m. Users of tetralin are warned as to its inflammable nature. Precautions are given
R. W. RYAN

Distant pressure control (in the distribution of gas). H. C. WIDLAKE. *Gas J.* **193**, 91–7(1931).—The object of a distant pressure indicator is to furnish at the works a continuous indication of the pressure prevailing at some selected point on a distant district. W. describes an instrument of his own design for this purpose. It is of the proportionate current type, *i. e.*, it maintains in its circuits a current of electricity which at all times is directly proportional to the pressure prevailing at the distant point. It consists of 2 parts (*a*) the transmitter housed at some distant key point, and (*b*) the indicator which is installed at the works. A sketch is given which shows in detail the construction of the app.
F. H. BERGEIM

Steam generation in gas works practice. W. GREGSON. *Gas J.* **193**, 215 (1931).—It is general practice to provide for all gas works power requirements with steam. The av. gas works requires 800–1200 lb. of steam per ton of coal carbonized, for power and process requirements. Steam can be generated in 2 ways: (1) by utilizing surplus heat from the retorts, (2) by firing boilers with coke breeze. The first method is most commonly used in modern works. Any well-run gas works can be self contained on "waste heat" steam alone for ordinary requirements. Coke breeze should only be used on the works when special steam requirements demand an excess over normal figures.
F. H. BERGEIM

Cheaper gas with off-peak electric power. PAUL MCMICHAEL. *Gas Age-Record* **67**, 1–5, 16(1931).—A central station can reduce the cost of generating electric energy to satisfy steady load by operating continuously at a rate approaching that of max. efficiency and selling any surplus energy for the cost of the fuel required for its generation. This surplus energy may be used to produce H and O for chem. and metallurgical processes. Pending a development of demand for this H and O the gases can be used by a gas company whenever the cost of off-peak power is no more than 1.90 mills per kw. hr. a. c. The O may be used to manufacture oil gas with which to enrich blue gas even when the off-peak energy cost exceeds 2.50 mills per kw. hr. a. c. H might be used for some process such as NH_3 synthesis pending development of a demand by chem. or metallurgical industries.
LESLIE B. BRAGG

Italian natural gas. M. G. LEVI AND C. PADOVANI. *Atti III congresso naz. chim. pura applicata* **1930**, 688–717.—The sources which contain definite, appreciable quantities of hydrocarbons higher than CH_4 are not more than 20, all in mountains or hills. It is probable that all, or almost all, of the Appenine sources contain small quantities of higher hydrocarbons. There is no great difference in the compn. of gas from mountains and of gas from plains, except that the latter contains more CO_2 and N_2.
E. M. SYMMES

Cleaning stack gases. JOHN B. C. KERSHAW. *Elec. World* **97**, 542–6(1931).—London power stations are washing the plant gases to eliminate dust and noxious gases. Three essentials for success of the treatment of flue gas are: (1) the placing of sprays

along the first flue to increase the humidity of the gases, with surfaces of Fe to assist in converting SO_2 to SO_3, (2) the provision of further sprays and of wetted contact surfaces in the second flue to continue the conversion and to effect the soln. of SO_3 and its elimination from the waste gases, and (3) the provision of further surfaces moistened with alkali for the total elimination of S from the gas. The Battersea power station is planned to fulfil 14 conditions named. The plan permits the use of an overall figure of 25 tons of water per ton of coal, and the time of contact allowed for ranges from a min. of 23 secs. to a max. of 44 secs. Corrugated plates of (*a*) Staybrite steel, (*b*) calorized steel, (*c*) a Si-Al alloy, and (*d*) tinned iron are being tried out to secure the necessary catalytic action. A close-grain cast iron or a Si-cast iron will be used for all pipe work and an alloy of Si and Cu or of cast Fe and Monel metal will be used for the circulating pumps and other machinery in contact with the wash water, and sprays of the centrifugal type will be constructed of a Si-Cu alloy. Cost estimates for gas washing (36c per ton of coal burned) are considered high. Results of exptl. trials of gas washing at Grove Road station of the London Power Co. in 1930 are tabulated.
W. H. BOYNTON

Automatic seal for water-gas plants. J. H. WAINWRIGHT. *Gas World* **94**, 56–7 (1931).—The differences between the ordinary method of water-gas manuf. and the back-run process are pointed out and the automatic seal box of the latter process is described in detail. F. H. BERGEIM

The coal water-gas plant at Plauen. MÜLLER. *Gas u. Wasserfach* **74**, 173–8 (1931).—This water-gas plant uses a "high pressure" water-gas generator with a revolving grate and a distn chamber in the upper part of the generator, a carburetor for cracking the vapors of the low-temp. tar and a superheater. This gas had a heating value of 370 B. t. u. per cu. ft. and a sp. gr. (air) of 0.56. The yield was 25.4 cu ft. of gas per lb. of coal. The cycle, analysis of the gas and some operating details are given. Although the plant has only been in operation a short time, it appears to have been successful. R. W. RYAN

Graphical determination of the calorific value of coal gas. A. ALISON. *Gas Eng.* **48**, 41–2(1931).—The construction of nomographs for the detn. of the calorific value of coal gas is described. CHANNING WILSON

Distribution experiences with dry coal gas. J. W. HARRISON. *Gas Age Record* **67**, 121–4, 130(1931).—Troubles from dust, varying gravity, naphthalene stoppages and gum formation, following a change from satd. water gas to partially satd. coke-oven gas with water gas addn. for peak loads, are discussed. Steam injection and oil fogging have been tried with partial success. LESLIE B. BRAGG

Nature and properties of certain hydrocarbons in coal gas and their effect on meter leathers. R. S. ANDREWS. *Gas J.* **193**, 158–59, 212–3(1931).—Unsatd. hydrocarbons occurring in the light oil content of carbureted water gas, particularly styrene and indene, polymerize in the presence of O_2 to gums and resins and deposit on the meter leathers and moving parts with detrimental results. These unsatd. hydrocarbons owe their origin to imperfect cracking due to the low temp. in the carburetor. Analytical data are given on the compn. of vertical retort gas, horizontal retort gas and carbureted water gas and also on light oils scrubbed from these gases. The tests show that of the 3 gases tested horizontal retort gas is by far the least damaging to meters and carbureted water gas the most damaging. The horizontal retort gas is the lowest in light oil and this light oil is the lowest in unsatd. hydrocarbons. Meter troubles have been accentuated by the presence of large percentages of continuous vertical retort gas. Methods of preventing meter troubles are, (*a*) efficient methods of washing and condensation, (*b*) avoiding low temp. in retorts, (*c*) maintaining low content of O in gas, (*d*) addn. of blue water gas, (*e*) introduction of semi-chrome tanned leather diaphragms, (*f*) correct selection of leather dressing, and (*g*) selection of a suitable position (where there is a min. temp. variation) for the consumers meter. F. H. BERGEIM

Determination of tar fog in coal gas with glass filters. HORST BRÜCKNER. *Gas u. Wasserfach* **74**, 183–4(1931). A very effective analytical filter for detg. tar fog in gas is illustrated. The filter consists of 2 fritted glass filters in a large tube, constricted at both ends. The inlet may be partly filled with cotton to remove larger particles and the other end of the filter tube is connected to the gas meter. Most of the tar fog is caught by the cotton and the first glass filter. The gas flow is stopped when a brown coloration first appears on the second fritted filter. Directions are given for carrying out accurate tar-fog detns. R. W. RYAN

The determination of the heating value of coke-oven gas with Junker's gas calorimeter. HUBERT GREWE. *Arch. Eisenhüttenw.* **4**, 75–85(1930).—A gas calorimeter with attachments for air-moistening and gas-cooling is described. H. S. VAN KLOOSTER

Development and technical accomplishment of a new process for the manufacture of hydrogen and hydrogen-nitrogen mixtures. G. Gluud, K. Keller, W. Klempt, R. Bestehorn, F. Brodkorb, J. Schröter and E. Curland. *Ber. Ges. Kohlentech.* 3, 211–370(1930).—The development of a process for the production of the cheapest possible H_2-N_2 mixts. (also H_2 alone) from coke-oven gas (and natural gas) is described, including theoretical calcns., lab. work and operation of a unit of 400 cu. m./hr. H_2 output. Existing H_2 processes from coke and coke-oven gas (Linde-Bronn liquefaction, D. R. P. 301,984) are considered less satisfactory than this process, whereby hydrocarbons are decompd. at atm. pressure with steam or steam-air mixts. in 2 steps to give H_2 contg. only 0.05–0.07% CO: (1) $CH_4 + H_2O = CO + 3H_2$; (2) $CO + H_2O = CO_2 + H_2$. Following scrubbing out of H_2S, step 1 takes place at 750–1100° in a two-chamber converter of chamotte (hottest chamber) and "nicrotherm." All org. S present is converted to CS_2. Under operating conditions, the Ni-MgO catalyst, supported on "R-Schamotte" (Haldenwanger) refractory rings, is S tolerant Gases are heated rapidly through the zone of possible soot formation by partial combustion with air. This reaction is also used to supply heat to the process. By use of air injection, exit gases from this first step have the approx. compn.: 2.6% CO_2, 0.04–0.08% CH_4, 16.3% CO, 55.8% H_2 and 25.3% N_2. Conversion of CO in step 2 is carried out over natural dolomite which serves both as a catalyst and absorbent for CO_2. Much depends on a proper dolomite, which has to be activated by burning at not over 850°. The large-scale operation of this step with 2 chambers and over a 40-hour cycle is described. Cost estimates for a 70 ton/day plant are given. Application of the process to natural gas is covered briefly. T. H. Chilton

The question of the carbon dioxide + oxygen content of furnace gas. J. W. Arbatsky. *Die Wärme* 54, 156–7(1931).—A $CO_2 + O_2$ content above 20.9% of a furnace gas is shown to result by the incomplete combustion of a coal of high O content. With some fuels, such as cellulose, it is possible to have a total $CO_2 + O_2$ content above 20.9% with complete combustion. Math. Allen S. Smith

Use of nickel and copper salt solutions for washing hydrocyanic acid out of coke gases. W. Gluud and W. Riese. *Ber. ges. Kohlentech.* 3, 437–51(1931).—Ni salts are effective in removing HCN from gases by forming first a sulfide and finally a double cyanide as follows: $NiS + 2NH_4CN \longrightarrow (NH_4)_2S + Ni(CN)_2$ and $Ni(CN)_2 + 2NH_4CN \longrightarrow (NH_4)_2Ni(CN)_4$. In the presence of NH_3, however, some of this double cyanide can be decompd to give $[Ni4NH_3](CN)_2$, the cyanide split off being converted into a thiocyanate. To avoid this, NH_3 is replaced by soda or potash, and the double cyanides of Na or K are formed. These are more sol and can reach high concns. in the wash liquid without impairing its efficiency. $Na_2Ni(CN)_4$ or $K_2Ni(CN)_4$ can be readily sepd. from the wash liquid by crystn., but the recovery of the Ni and alkali salts from the double cyanides is not as yet a commercially feasible process. In the use of Cu salts, $K_3Cu(CN)_4$ or $(NH_4)_3Cu(CN)_4$ are formed, but these compds. are not quite as stable as the corresponding Ni salts, being quite sensitive to carbonic acid. With increasing concn. of the double cyanide in the wash liquid its efficiency decreases. The same difficulty in recovery of the Cu salts is encountered as with Ni. H. Stoertz

Removal of hydrogen sulfide and hydrocyanic acid from crude benzene. K. Keller. *Ber. ges. Kohlentech.* 3, 429–36(1931).—In the presence of air and small quantities of NH_3, H_2S is readily removed from crude benzene by conversion to $(NH_4)_2S$ and subsequent oxidation to $(NH_4)_2S_2O_3$. A small amt. of H_2O is necessary. HCN is also removed simultaneously with H_2S by conversion to NH_4CNS. H. S.

Benzene recovery (in gas works). Friedrich Goldschmidt. *Gas u. Wasserfach* 73, 636–7(1930).—Efficient gas cooling will permit the tar to remove a large portion of the naphthalene. In practice, a naphthalene content of 10–15% in the wash oil must be allowed to secure a reasonable life for the wash oil. Higher concns. of naphthalene may cause naphthalene deposition behind the benzene washers or in the purifiers. Fresh wash oil is added from time to time to replace that carried away by the light oil. Both the preheating and cooling surfaces should be great enough to avoid losses when water is present. The wash oil may be successfully preheated to 130–145° without thickening, contrary to earlier belief, and steam distn. of the wash oil to 0.3% benzene may be carried to 180°. The test of efficient benzene removal from gas is not the percentage extn., but rather the amt. of benzene remaining in the gas. R. W. Ryan

Some observations on the composition and recovery of crude benzene produced under different carbonizing conditions. S. Tweedy. *Gas World* 94, 15–8(1931).—Crude benzene is mainly a coke-oven or gas-works product of boiling range 65–190°. Typical analyses (% by vol.) of crude benzene produced by carbonization in the hori-

zontal retort, in the vertical retort and in the coke oven are, resp., benzene 61.2, 32.5, 61.7; toluene 19.9, 14.0, 15.0; xylene (and light naphtha) 9.7, 24.4, 10.0; heavy naphtha —, —, 8.0; paraffins 1.6, 15.3, —; loss on washing 7.1, 13.4, 5.3. The compn. of the crude benzene varies with the time of carbonization when only one system of carbonization is used. A silica regenerative coke-oven battery gave crude benzene of the following compns. when operated under the carbonizing times of 29.5 hrs. and 16.2 hrs., resp.: benzene 42.9, 62.0; toluene 20.3, 17.9; solvent naphtha 6.8, 5.3; paraffins up to 140° 5.6, 1.1; CS_2 0.1, 0.1; washing loss 8.5, 3.1; and benzene residues 7.1, 5.2. Other important factors besides time which influence the compn. of crude benzene are (1) type and size of oven, (2) carbonizing temp., (3) uniformity of heating, (4) the degree to which the oven is filled with the charge, (5) class of coal, (6) moisture in the coal and (7) operation of the oven. Figures are given showing the absorption efficiencies of benzene in gas oil at varying temps. F. H. Bergeim

The refining of motor benzene by means of silica gel. R. C. Geddes. *Gas World* 94, Coking Section, 9–12(1931).—The silica gel process gives a greatly increased yield over the usual H_2SO_4 refining process. Where 72% is the normal yield in the old type of plant employing a once running still for refractionating the crude recovered benzene silica gel gives 85%. In a modern plant with efficient stripping stills, and the primary once running still eliminated, where 86% is being obtained, the yield with the silica-gel process is 93%. The following data give a comparison of the results of the H_2SO_4 and the silica-gel processes. By starting in each case with crude benzene of the following % compn.: diolefins 1, olefins 10 and aromatics 89 the resultant benzene refined with strong H_2SO_4 is diolefins 0, olefins 0 and aromatics 89 parts. With dil. H_2SO_4 and with silica gel the resp. figures are: 0.25, 2.5, 89 and 0, 9.5 and 89. The high yield in the silica-gel process is due to the retention of the stable unsatd. compds. which are not only not harmful to motor benzene but also have a definite antiknock value. In the silica-gel process the polymerization of the undesirable unsatd. compds. is started by the treatment with dil. H_2SO_4. The polymerization is accelerated by the catalytic action of silica gel at 150°. A unit wt. of silica gel will treat 1500 times its wt. of oil before activation becomes necessary. The general layout of a silica-gel refining plant is given. F. H. Bergeim

Construction of waterless gas holders. L. Hartley. *Gas World* 94, 61–2(1931). A review is given of the structural features of waterless gas holders. F. H. Bergeim

Measurement of the amount of dust and tar in generator gas. Gustav Neumann and Franz Strähuber. *Arch. Eisenhüttenw.* 4, 151–4(1930).—An *app.* was developed for the detn. of dust and tar in generator gas, which is suitable for the collection of the coarse and fine dust coming from the generators over longer periods of time. The 2 main parts are the collection chambers, also serving as cooling chambers, and the filters. A tube of NCT steel proved suitable as a collection tube. Cotton was used as a filter material. An av. analysis of the gas showed the presence of 8.65 g. of dust, of 11.35 g. of tar and of 55.80 g. per cu. m. of dry gas. Leopold Pessel

The free carbon in coal tar. J. Marcusson. *Chem.-Ztg.* 54, 795–6(1930). Tars from a vertical still and from a horizontal still are compared. The amt. insol. in CCl_4 was 7 and 24%, resp. The benzene-sol. part contained 8.6 and 0.5% of hydroxy acid, 73 and 16.3% of pyridine-sol. resins, 18.4 and 52% of pyridine-insol. resins and 0 and 51.2% coke, resp. A. L. Henne

Extraction of bases from primary tar by water of condensation. A. Travers and Franquin. *Compt. rend.* 191, 951–2(1930).—Detn. of the amt. of pyridine bases in the water of condensation from tar is difficult because their concn. is only about 0.1%, and NH_3 is present in 6–7 times as high a concn. Extn. of the bases by an org. solvent, *e. g.*, PhH, takes up about 90% of the phenols present in the water and a considerable proportion of the bases but complete extn. is impossible because an equil. is established between the aq. and the hydrocarbon phases. The presence of the pyridine bases improves the extn. of phenols on account of the formation of addn. compds. The best lab. procedure is to sep. the phenols by distg. from 30% NaOH, wash the distillate which contains all the NH_3 and bases 5 times with 50% of its vol. of Et_2O, distil off the Et_2O at 0°, remove the NH_3 from the residue by blowing CO_2-free air through at 0°, then add 40% NaOH soln. and read volumetrically the amt. of base liberated. Applied to the PhH used in extg. phenols, this method shows 7–8 g. of bases per l. in PhH. C. H. Pelt

Determination of phenols in primary tars. I. Ubaldini and O. Mochi. *Atti IIo congresso naz. chim. pura applicata* 1930, 782–91.—Detn. of phenols in tars may give results varying from 30 to 20% phenols. An improved method is to put 20 g. of tar in a vacuum-walled vessel, add 10 cc. of NaOH soln., d. 1.332, the tar and NaOH soln

being at the same temp. before mixing. The 2 are mixed, stirred with a glass rod and the max. temp. reached during the reaction is observed with a thermometer reading to 0.1°. The max. temp. is reached a very few sec. after mixing, and lasts long enough for reading. Dividing the rise in temp. by 0.42 gives directly the % of phenols present. E. M. SYMMES

Production of hydrocarbons from phenolic tars. C. PADOVANI AND E. DE BARTHOLOMAEIS. *Atti III congresso naz. chim. pura applicata* **1930**, 792–819.—It was possible to convert into hydrocarbons the primary lignite-tar fraction passing over at 200–300° and sol. in boiling soda soln. by heating to 750–800° in an atm. of H_2 and nascent H formed by the action of water in Fe. The best results were obtained with 100 g. of phenols heated for 2 hrs. at 780° in a tube 3 m. long, in the presence of water vapor and H_2, forming 36.16 g. of dephenolated oil b. below 200°, about half of which was pure C_6H_6. This yield can be increased by increasing the size of the tube and thus the contact surface. E. M. SYMMES

Investigations on commercial primary lignite tar from Valdarno. M. G. LEVI, C. PADOVANI AND I. UBALDINI. *Atti III congresso naz. chim. pura applicata* **1930**, 767–77.—Total analyses and fractional distn. of lignite tars are shown. E. M. SYMMES

Coking and decomposition heats of coal. III. ERNST TERRES AND KARL VOITURET. *Gas u. Wasserfach* **74**, 98–101, 122–8, 148–54, 178–82(1931); cf. *C. A.* **22**, 3035.—A new method has been devised for detg. heats of coking of coal with greater accuracy than heretofore by altering the method of operating the calorimeter. This new method is based on the fact that the heat content of the empty system is a straight-line function of temp. between 600 and 1100° and is independent of the heating time or amt. of heat applied. The heat of coking is the difference between the total amt. of heat supplied to the system and the heat taken by the calorimeter up to the shut-off point, less the heat content of the system at the given temp. The heat content of the gaseous products need be known only for calcg. the heat of decompn. Heat of coking curves are shown for 15 coals over the range from 600 to 1200°. These curves vary widely with the various coals, and no relation can be found between the curves and analytical data for the coal. The heat of coking of a given coal is reduced by storage and this decrease is somewhat proportional to time of storage. Heats of coking and heats of decompn. of 30 coals at 1000° are plotted against each other and fall on a smooth curve, permitting the estn. of the heat of decompn. of a coal when the heat of coking is known. The max. heat of decompn. of any coal is +50 kg. cal./kg. while many coals show neg. heats of decompn. The heat of coking of "pure" coal was shown to be 325 kg. cal. per kg. This investigation is being continued in the hope of applying the results to the coking process. R. W. RYAN

Coking a banded bituminous coal. C. P. FINN. *Iron Coal Trades Rev.* **121**, 949 (1930); **122**, 3; *Gas World* **94**, Coking Section, 2–5(1931). See *C. A.* **25**, 1659. LESLIE B. BRAGG

Coke-oven operation and maintenance. F. J. PELUKE. *Am. Gas J.* **134**, No. 2, 11–4, No. 3, 37–41, No. 4, 75–8(1931); cf. *C. A.* **25**, 1361. E. H.

The formation of fractures in coke. R. G. DAVIES AND R. V. WHEELER. *Gas World* **94**, 16–7(1931).—Carbonization results confirm Thau's previous work that cracks appear near the walls of the oven shortly after the start of the coking process rather than at a later stage, a short time before the carbonization is completed. F. H. BERGEIM

Coke for domestic fires. H. J. HODSMAN. *Gas World* **94**, Coking Section, 23–4 (1931).—A review is given of the progress of coking technology. F. H. BERGEIM

Continuous verticals. W. A. CURRIE. *Gas J.* **193**, 280–1; *Gas World* **94**–5 (1931).—The effects of temp., rate of carbonization and coal size on the products of carbonization are discussed. A high temp. is favorable to a large throughput, and gives a high yield in therms per retort. A formula is given for the calcn. of the optimum throughput of coal based on the free space in the charge and the swelling power of the coal. F. H. BERGEIM

Circulating-stream coke ovens. O. PRISCHER. *Stahl u. Eisen* **50**, 761–7(1930).—This type of coke oven has twin flues, and a portion of the burnt gases is drawn by suction back into the incoming stream of heating gas and air so as to retard the combustion, avoid overheating and regulate the heat flow from gas to coking retort. A furnace of this kind is described and illustrated diagrammatically, and a brief account is given of its operation. B. C. A.

Some additional volume data for superheated steam (SMITH, KEYES) **2**. The relative merits of gas, oil and electricity for industrial purposes (HOPKINSON) **13**. Miner-

alogy of the coal fields (BELLIERE) **8.** Automatic analyzers of gas mixtures based upon thermal conductivity of gases and their industrial uses (DE FROBERVILLE) **1.** Lignin, humic acid and humin (FUCHS) **10.** Utilization of sewage gas (KUISEL) **14.** Chemical properties and examination of tar and pitches (BOCKSHAMMER) **22.** Automatic gas-analysis apparatus (Brit. pat. 337,862) **1.** Recovery of oils from mixtures such as destructive hydrogenization products of brown coal (U. Von den Kohlen und den Mineralölen, 1930. Bd. III. Ein Jahrbuch für Chemie und Technik des Brennstoffe und Mineralöle. Edited by Fachgruppe für Brennstoff- und Mineralöl-Chemie der Vereines Deutscher Chemiker. Berlin: Verlag Chemie. 238 pp. M. 17.

Fuel, etc. TROCKNUNGS-, VERSCHWELUNGS-, UND VERGASUNGS-G. M. B. H. Ger 482,559, Feb. 3, 1928. Material to be treated thermally in dust form, *e. g.*, coal dust, is prevented from mixing with gaseous products by elec. cohesion.

Fuel briquets. DONALD S. ANDREWS. U. S. 1,793,833, Feb. 24. In making fuel briquets with an anthracite base, culm 85–90, asphalt 5–10 and pulverized bituminous coal about 5% are used together. The asphalt is rendered freely fluent by heating, the culm is heated to about the same temp. and mixed with the asphalt and the bituminous coal is then added and intermixed.

Fuel briquets. HANS HERTIG. Swiss 142,960, April 17, 1930. Briquets are made by mixing sawdust with 8–30% of adhesive substance (*e. g.*, water glass soln.) and pressed.

Pressing fuel briquets. FIRMA CARL STILL. Ger 514,888, Sept. 3, 1929.

Carbonizing fuel briquets. MAUREL INVESTMENT CORP. Brit. 337,600, Oct. 31, 1929. Briquets of ground coal and a hydrocarbon binder are passed through a liquid seal into a distg. zone where they are heated solely by indirect heat, and then through a second liquid seal and into a hardening zone and finally into a vertical retort. Various details of app. and operation are described. Cf. *C. A.* **25**, 192.

Distilling and gasifying solid fuels. METALLGES. A.-G. Brit. 337,721, May 2, 1929. Gasification and distn. of solid fuel are effected as it passes through a vertical shaft comprising a drying zone, distg. zone, gasifying zone and cooling zone. Steam is superheated by heat from preheated refractory bodies and is introduced below the gasifying zone. Gases for heating the fuel are passed through the app. countercurrentwise and tar or heavy or light oils may be mixed with the gases to increase the heating value of the gases produced, or O may be added to the gas or steam supplied to the app. Various details of construction and operation of the app. are described.

Catalytic treatment of volatile engine fuels. FERNAND C. F. PORTAIL (to Soc. anon. le carbone). U. S. 1,795,037, March 3. Air and fuel are brought into contact with very active porous C at a temp. of 300–400°, in order to facilitate subsequent complete combustion with addnl. air. App. is described.

Destructive hydrogenation. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 338,192, Aug. 14, 1929. Hydrogenation under pressure of such materials as tar, petroleum products and residues, lignite and cellulose is effected with a catalyst consisting of a Mo compd. carried on adsorbent material such as adsorption charcoal or finely divided coal. In prepg. the catalyst, an aq. soln. of NH_4 molybdate, acidified with H_2SO_4, may be treated with H_2S to form a blue colloidal soln. to which "Carboraffin" or finely divided brown coal is then added, followed by filtration, washing and drying first at ordinary temp. and then at 50–60°. Various examples with details of the hydrogenation of brown coal and gas oil are given. Cf. *C. A.* **25**, 1362.

Fuels from coal and oil. TRENT PROCESS CORP. Brit. 337,920, Oct. 20, 1928. In a process involving coal and oil amalgamation, as generally described in Brit. 228,862 (*C. A.* **19**, 3011) and Brit. 262,302 (*C. A.* **21**, 3733), the amalgamation is first effected with a light oil such as "navy fuel oil" and the process then completed by addn. of a heavy oil (suitably with intermediate removal of ash content and change of water). Proportions used may be coal 85, light oil 5.0–7.5 and heavy oil 10–7.5%. Cf. *C. A.* **24**, 1735.

Decomposing coal. DEUTSCHE BERGIN A.-G. FÜR KOHLE- UND ERDÖLCHEMIE. (Wolf Grote, inventor). Ger. 517,317, July 12, 1928. In the destructive hydrogenation of coal at a high temp. and pressure, the production of coke-like and asphaltic products is hindered by addn. of a mixt. of Fe_2O_3 75–60 with Na_2CO_3 25–40 parts, with or with-

out a little alk. earth carbonate. About 10 parts of the mixt. may be added to 140 parts of coal.

Apparatus for pneumatic separation of solids of different densities as in purifying coal. J. F. C. FRIEND. Brit. 337,458, Aug. 2, 1929. Structural features.

Furnace for coking coal and heating a boiler or the like by the heat developed in coking. T. KOMATSU. Brit. 338,435, Feb. 6, 1929. Structural features.

Retort for destructive distillation of coal or lignite. H. HARDY. Brit. 338,047, Jan. 3, 1929. A drum is provided with a hollow shaft for admission of heating gases and evacuation of combustion products. The drum contains combustion chambers, distn. chambers and gas-outlet chambers, and progressive heating is provided either by rotation of the retort on the hollow shaft or by rotation of the latter while the retort is stationary. Various structural details are described.

Plate drier for lignite. "EINTRACHT" BRAUNKOHLENWERKE UND BRIKETFABRIKEN and MAX MAYER. Ger. 514,711, Feb. 7, 1929.

Smoke consumers. GEORG KORNECK. Ger. 514,975, April 15, 1926. Addn. to 500,932 (*C. A.* **24**, 4670). App. for burning the smoke and flue gases in furnace plant is described.

Condenser suitable for steam condensation. PELLE ANDERSSON (to Allis-Chalmers Mfg. Co.). U. S. 1,792,796, Feb. 17.

Combustible gas containing hydrogen and carbon monoxide. HERBERT A. HUMPHREY (to Atmospheric Nitrogen Corp.). U. S. 1,794,232, Feb. 24. In a continuous gas-producing process a mixt. comprising steam and O, preheated to above 1000°, is passed into and through a gasification chamber and finely divided solid fuel is fed into the chamber to contact and react with the preheated mixt and to generate gas at such a high temp. that CO and H substantially free from CH_4 or other hydrocarbons and CO_2 are produced; the hot generated gas is led into and through a second preheating stage and from the latter combustible gas is withdrawn. A reversal of flow of the mixt. contg. steam and O is effected whenever its temp. immediately prior to its contact with the fuel tends to fall materially below 1000° and (irrespective of the direction of gas flow) the particles of solid fuel are maintained in suspension in a relatively large mass of enveloping gas in the reaction chamber. App. is described.

Gas from coal distillation. I. G. FARBENIND. A.-G. Brit. 338,153, May 14, 1929 Bituminous coal is distd. by heating it in granular or finely divided form in a heat accumulator which is periodically heated to about 900°; residual coke may be gasified and the producer or water gas passed through the heat accumulator to heat it. Various details of app. and operation are described.

Dry purifier for coal gas, etc. FRANCKE WERKE A.-G. Ger. 517,320, Aug. 24, 1928. Structural features are described.

Fuel gas. MATHILDE LOTZ NÉE BLICKLE, AUGUSTE LOTZ, ARTHUR LOTZ, MATHILDE SPANKE NÉE LOTZ, MARIA KOWSKY NÉE LOTZ, ROBERT LOTZ and WALTER LOTZ. Ger. 517,414, Apr. 22, 1928. Addn. to 513,233 (*C. A.* **25**, 1364). When using coal that shrinks only slightly or not at all on gasification, the method of Ger. 513,233 is modified by gasifying the coal so that a layer of partly gasified coal is obtained on a layer of coke. Steam is then led into the coke layer, the water gas so produced passing through the upper layer.

Gas mixtures. GIULIO NATTA. Swiss 141,827, Mar. 7, 1929. A gas mixt. of CO, H and CO_2 contg. at least twice as much H as oxide of C, is obtained by passing an O and steam current (contg. at least twice as much steam as O) over C at about 700° and not over 750°. Cf. *C. A.* **24**, 5765.

Mixed water gas and coal gas. EDWARD A. DIETERLE. U. S. 1,792,632, Feb. 17. A hot bed of solid carbonaceous fuel is intermittently blasted with air, and steam is intermittently passed through it upwardly. Powd. carbonaceous material is intermittently introduced above the hot fuel by causing the powd. material to pass downwardly through a vertically disposed retort positioned above the fuel bed and externally heated by the rising hot gases which are generated to effect distn. of the powd. material before it encounters the hot fuel and the generated blue water gas; the resulting gases and entrained vapors are subjected to further fixing by passing them through vertically arranged elongated heated passages above the main fuel bed and around the retort App. is described. Cf. *C. A.* **24**, 949.

Water gas. I. G. FARBENIND. A.-G. (Fritz Winkler and Rudolf Augsten, inventors). Ger. 517,469, Feb. 22, 1928. Addn. to 437,970. For the continuous manuf. of water gas from granular fuel, which may contain dust, steam is blown into a shaft contg. the fuel so that the fuel is whirled about in the shaft, and the necessary heat is supplied by heating elements located in the shaft. Cf. *C. A.* **24**, 5986.

Continuous water-gas production. I. G. FARBENIND. A.-G. Brit. 337,807, Aug. 6, 1929. Fuel such as brown coal, small coal, semi-coke or peat is passed downwardly through externally heated vertical retorts supplied with steam (preferably superheated to about 800° while the fuel is heated to about 500° and the retort heating flues are heated to about 1200°). Distn. gas from the upper part of the retort is collected separately from the water gas from the lower portions. Various details for continuous operation are described, also of app. construction.

Automatic control system for electric valve operation in apparatus for generating water gas. JAMES S. KENNEDY. U. S. 1,794,906, March 3. Mech. and elec. features.

Apparatus for producing oil gas by partial combustion of heavy oil with superheated air and steam. C. CHILOWSKY. Brit. 338,281, Jan. 18, 1929. An atomized jet of oil, superheated steam and air issues from a nozzle and impinges against a crucible which may be of graphite or carborundum or non-oxidizing steel and in which eddy currents are set up; the flames pass in contact with the outer walls of the crucible and the products of partial combustion are then discharged through a catalyst (or the crucible itself may constitute a catalyst). Various details of construction are described. Cf. *C. A.* **24**, 2583.

Gas producer. HARRY F. SMITH (to Gas Research Co.). U. S. 1,794,478, March 3. Automatic control is provided for effecting communication between the offtake and a vent pipe or delivery main in accord with the quality of the generated gas, and various structural details are described.

Gas-producer plant. POWER-GAS CORP., LTD., and N. E. RAMBUSH. Brit. 337,825, Aug. 9, 1929. Various details are given of the construction and operation of a plant comprising a generator or producer, a waste heat boiler, a generator jacket boiler and a tubular superheater, two sets being used (alternately on "run" and "blow") for making water gas.

Gas producer (with a rotatable fuel shell and rotatable ash pan). ANSON K. BRADLEY (to Morgan Construction Co.). U. S. 1,795,162, March 3.

Gas producer (with a rotary ash pan). PHILIP S. HULT (to Morgan Construction Co.). U. S. 1,793,618, Feb. 24. Structural features.

Gas producer adapted for directly heating steam boilers. W. B. CHAPMAN. Brit. 337,388, July 29, 1929.

Apparatus for distributing granular fuel to gas producers or for similar purposes. A. JADOUL. Brit. 338,141, July 11, 1928. Structural features.

Domestic gas plant for generating gas from oil and vegetable materials. JOSEPH S. BIRTCIEL (one-fourth each to E. A. Rodgers, John S. Fogarty, Gerald Redmond and Homer L. Baughman). U. S. 1,795,005, March 3. Structural features.

Apparatus for washing flue gases with water sprays. J. T. BARON and J. B. CLARKE. Brit. 337,436, July 1, 1929. Structural features.

Gas holder. E. CHUR. Brit. 337,711, March 7, 1929.

Purifying furnace gases. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 337,448, Jan. 9, 1929. Furnace gases which are to be passed through a separator such as an electrostatic pptn. app. are preliminarily brought to a uniform temp. and humidity by an app. automatically controlled by a thermometer and hygrometer. Various details of app. are described.

Removing naphthalene from coal gas. C. OTTO & Co., GES. (to N.-V. Silica en Ovenbouw Mij). Brit. 337,723, May 17, 1929. A solvent for naphthalene such as xylene is introduced into the gas in atomized or nebulized form, followed by electrostatic pptn., sepn. of solvent from the naphthalene and reuse of the solvent.

Separating ammonia and hydrogen sulfide from gases. CHRISTIAN HANSEN (to I. G. Farbenind. A.-G.). U. S. 1,795,121, March 3. In treating gases such as coal gases most of the NH_3 content is sepd. by treatment with water, and the residual gases are then washed in 2 stages, in the first stage, with the aid of a soln. contg. NH_4 thiosulfate, SO_2 and NH_4 polythionate, such a part of the H_2S is pptd. in the form of S that for the washing of the residual H_2S in the second stage a neutral NH_4 sulfite-bisulfite soln. suffices which is produced from the sepd. NH_3 and S.

Ammonia and hydrogen sulfide absorption simultaneously from industrial gases. CHRISTIAN HANSEN (to I. G. Farbenind. A.-G.). U. S. 1,795,120, March 3. Absorption of NH_3 and H_2S from gases such as coke-oven gas or illuminating gas is effected in a 2-stage process in the first stage of which is used "ammonium sulfite disulfite" wash liquor having a lower ratio figure of SO_2 to NH_3 than about 1.5, and in the second stage of which there is used an "ammonium sulfite bisulfite" wash liquor having a higher ratio figure of SO_2 to NH_3 than about 1.5.

Storing explosive gases. AUTOGEN GASACCUMULATOR A.-G. Ger. 514,722, Mar 2.

1928. Porous raw material is extd. and evacuated to remove substances such as resin, fat, gas, etc., and then filled into vessels to store such gases as C_2H_2. Cf. *C. A.* **24**, 4921.

Storing acetylene, etc. INDUSTRIEGAS A.-G. ZWEIGNIEDERLASSUNG WAGIRO-DISSOUSGASWERKE (Gustav Offe, inventor). Ger. 517,351, Sept. 24, 1929. Peat or like bituminous substances mixed with active C, or with flue dust from boiler furnaces, are used as a filler for containers in which C_2H_2 or other gas is to be stored in soln. under pressure.

Distilling tar. T. O. WILTON and CHEMICAL ENGINEERING & WILTON'S PATENT FURNACE CO., LTD. Brit. 337,581, June 13, 1929. In distg. tar by a process such as that described in Brit. 307,577 (*C. A.* **23**, 5308), more intimate mixt. of the crude tar and the pitch from the process is obtained by introducing them side by side through pipes into a const.-level tank. Various details of app. and operation are described.

Coking tar or molten pitch, etc. E. O. RHODES (to American Tar Products Co.). Brit. 337,800, Feb. 9, 1929. The material to be coked is sprayed into a heated coke oven in the presence of an inert gas such as steam (preferably after a preliminary distn. of tar if the latter is used). Various details of app. and procedure are described.

Coke and distillation products from coal. RICHARD H. CARR and CORNELIUS B. WATSON (to Pure Oil Co.). U. S. 1,793,838, Feb. 24. Various details of app. and procedure are described for low-temp. distn.

Vertical-flue coke oven. C. OTTO & CO., GES. (to N.-V. Silica en Ovenbouw Mij). Brit. 337,667, May 9, 1929.

Vertical-flue coke oven. J. VAN ACKEREN (to Koppers Co.). Brit. 337,801, April 25, 1929. Numerous details of construction and operation are described.

Vertical coking retort and charging and discharging apparatus. T. TOPPING and J. S. BLACK. Brit. 337,842, March 27, 1930.

Coke-oven gas-reversing valve. COLLIN & CO. Brit. 338,040, Dec. 27, 1928.

Coke oven (door construction). CARL STILL. U. S. 1,795,239, March 3.

Apparatus for operating a coke-oven door. RAYNARD CHRISTIANSON (to Koppers Co.). U. S. 1,793,456, Feb. 24. Structural features.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

Quinquennial review of the mineral production of India for the years 1924 to 1928. Petroleum. E. H. PASCOE *Records Geol. Survey India* **64**, 257–73(1930); cf. *C. A.* **24**, 4245.—Indian oil production from 1924 to 1928 declined, although 1928 was a banner year. The country contributes less than 1% of the world's marketed supply. World's production and consumption are reviewed and the individual Indian fields discussed in detail. ALDEN H. EMERY

The total heat and specific heat of a series of fractions of petroleum oils and their relation to other properties. H. R. LANG, R. JESSEL AND A. H. STEED. *J. Inst Petroleum Tech.* **16**, 783–813(1930).—This paper gives the 1st results of a planned systematic study of the phys and particularly the thermodynamic properties of petroleum oils. A Miri (Borneo) petroleum was sepd. into 5 fractions with little overlapping. Sp. heat, total heat, their variation with temp., *n*, mean mol. wt., sp. gr. and coeff. of expansion were measured. Variations of the sp. heat, temp. curve from the straight-line relation are explained at low temps. by the presence of C_6H_6, with its high f. p., at high temps. by the presence of vaporized mols. and intermediately, by some aggregate forming tendency of the mols. Total heat above 100° was measured by Callendar's continuous-mixt. method. Sp. gr. and *n* were strictly linear with respect to mean mol. wt. EMMA E. CRANDAL

The isolation of the isomers of hexane from petroleum. JOHANNES H. BRUUN AND MILDRED M. HICKS-BRUUN. *Bur. Standards J. Research* **5**, 933–42(1930).—*n*-C_6H_{14}, $Me_2CHCHMe_2$, $Me_2CHCH_2CH_2Me$ and $MeCH_2CHMeCH_2Me$ were isolated from an Oklahoma crude petroleum, but the 5th isomer, Me_2CCH_2Me, was not found. Ordinary fractional distn. concd. the hexanes in a set of const.-boiling mixts., the other constituents of which were ring compds. The const.-boiling mixts. were broken up by distn. after the addn. of an alc. (MeOH or EtOH) which was later removed from the distillate by washing with H_2O. The f. ps. for air-satd. $Me_2CHCH_2CH_2Me$ and $MeCH_2CHMeCH_2Me$ are —143 ± 0.5° and —118 ± 0.5°, resp. The eutectic for the system CO_2–$Me_2CHCH_2CH_2Me$ is —153 ± 0.5° R. E. SCHAAD

The electrical conductance of hydrocarbons in thin films. L. BRÜNINGHAUS. *Compt. rend.* 192, 151–3(1931); cf. *C. A.* 24, 4142.—Films of oil 1μ thick become highly conductive to 110 v. d. c. and remain so until the electrodes are sepd. by 15μ. Conductance is always preceded by a semi-conducting stage. This is doubtless due to ions similar to those in gases. V. F. HARRINGTON

Refining mineral oils with adsorbents. BALDASSARRE SALADINI. *Atti III congresso naz. chim. pura applicata* 1930, 584–606; cf. *C. A.* 24, 1963.—Tests were made with shale oil, but the results apply to other high-S oils. Active C decolorizes indifferently and desulfurizes little. Decolorizing earths give rather complete decolorization and appreciable desulfurization. SiO_2 gel decolorizes less than the above, but desulfurizes better. In general, desulfurization follows the adsorption of colored substances. Bauxite, calcined at high temp., has an appreciable desulfurizing effect and polymerizing properties. Alternate use of bauxite and decolorizing earths on crude oil gives the best results and an economy in adsorbent. Decolorization is rather complete; desulfurization reaches 50%; the oil has a pleasant, ethereal odor and is stable. Regeneration of the treating materials is effected by calcination, which allows recovery of oil and S. E. M. SYMMES

Separation of obstinate crude-oil emulsions. The L. Berkhan patent. E. PYHÄLÄ. *Erdöl u. Teer* 6, 478–80(1930).—Caspian crude oils, emulsified with H_2O that contained clay and $MgCl_2$, could not be sepd. by ordinary settling. Serious corrosion troubles made drying operations or utilization as boiler fuel impossible. The possibility of centrifugal sepn. was demonstrated in lab expts. The Berkhan method is in successful operation. Sepn. is induced by an admixture of 0.5% of kerosene-naphthenic acids and settling of the warm mixt. It was shown experimentally that the emulsions were stabilized by traces of ozocerite. Naphthenic acids dissolve the stabilizer and lower the surface tension of the oil. K. H. ENGEL

Cracking processes in the Russian petroleum industry. I. SINGER. *Petroleum Z.* 25, 893–906(1929); 26, 482–91(1930); cf. *C. A.* 24, 3634, 4619 20.—Three types of cracking processes are described which serve for the production of (1) fuel oil of a better quality as regards η and cold test, cracking being carried out at 425° and under 10–60 atm.; (2) gasoline and fuel oil; and (3) gasoline and coke, in which the treatment is carried out at 450° and 20 atm. These processes were utilized in the cracking of Grosni and Surakhani mazouts and of various heavy crude oils. The results obtained with Grosni mazout show that gentle cracking (first method) causes a decrease in the cold test of the fuel oil obtained. In the second method, with a 1% yield of coke, 35% of cracked benzine is obtained; the quantity of coke formed is independent of the temp. but is const. with equal gasoline yields. With 15% of coke in the third method, 57% of cracked gasoline is produced. The following conclusions have been reached: (*a*) Greater yields of light products cause an excessive formation of coke and deteriorate the quality of the residue. (*b*) The velocity of the reaction is doubled for each rise in temp. of 10°. (*c*) The rate of coke formation depends on the chem. compn. of the cracked petroleum products. Paraffinic products yield less coke than paraffin free or asphaltic products. Kerosene yields practically no coke; solar and spindle oils yield very little; machine and cylinder oils yield large quantities and tars greatly increase the formation of coke. (*d*) Increase of pressure causes a decrease in the content of unsatd. hydrocarbons; paraffin hydrocarbons yield no coke on cracking, while aromatic hydrocarbons tend to give significant quantities. (*e*) The extent of the production of cracked gasoline and kerosene from heavy crude oil and mazout is practically the same. (*f*) The details of a cracking process are detd. not so much by the yields of cracked gasoline (which are the same for a given temp. and cracking time with heavy crude oils and mazout) as by the yields of coke, which vary for different petroleum products. The cracking of Grosni oil tar and paraffin tar is not important on account of the excessive quantities of coke formed. B. C. A.

Refining of cracked gasolines. P. M. EDMOND SCHMITZ. *Erdol u. Teer* 6, 493–4, 510–2(1930).—Raw gasoline treated cold with NaOH (30° Bé.) or hot with fuller's earth showed discoloration and gum formation on standing, even in the dark. Washing with NaOH should be followed by treatment with H_2SO_4 (strength 1%). A gasoline of excellent color and stability was obtained by a *vapor-phase purification* (100–20° above the highest b. p.) *over* Fe_2O_3. Various brands of fuller's earth, instead of Fe_2O_3, were less effective. Dry $CaCl_2$ and NaOH were practically ineffective. K. H. ENGEL

Compression pressure is controlling factor in inducing engine knock. SANDOR D. RUBENZ. *Automotive Ind.* 63, 20–3(1930).—Antiknock rating of a fuel is detd. on a single-cylinder Liberty engine by comparing the max. of the manifold vacuum-air-fuel

ratio curve with those of similar curves obtained for known blends of com. C_6H_6 in domestic aviation gasoline. "The constancy of the manifold vacuum points of incipient knock leads to the conclusion that, other things being equal, the compression pressure is the controlling factor in inducing knock." Antiknock value of gasoline for air-craft engines can be detd. only if the base fuel is specified when C_6H_6 rating is given. With "cold-running" (large central electrode) and "hot-running" (small central electrode) spark plugs, manifold vacua at incipient knock are almost identical. In this Liberty engine the tendency to knock is greater with 2 plugs than with 1, although 2-plug ignition is usually stated to reduce knocking. R. E. SCHAAD

X-ray studies on paraffin wax and petrolatum. SHINSUKE TANAKA AND AKIRA TSUJI. *Mem. Coll. Sci. Kyoto Imp. Univ.*, Ser. A, **13**, 369–73(1930).—The effects of temp. and mech. operations were studied by taking photographs of the x-ray diffraction patterns. *Influence of Temp.*—The photographs taken at temps. lower than the m. p. have many spectral lines characteristic of cryst.-powder photographs. These lines generally decrease in intensity as the temp. rises and vanish when the substances are melting. Amorphous bands appear in other positions. One intense line, however, remains until melting is reached and then suddenly vanishes. This transformation occurs in a different manner for each substance. *Effects of Mech. Operations.*—The effect of compression and rolling at room temp. was studied with paraffin wax with the following results: (1) The wax acquires a fibrous structure, the axis of which is perpendicular to the surface of compression and rolling. (2) The crystal planes which produce the most intense reflection are also nearly perpendicular to the surface of compression and rolling. C. J. HUMPHREYS

Electrochemical oxidation of paraffin. II. I. A. ATANASIU. *Ber.* **64B**, 252–60 (1931); cf. *C. A.* **24**, 2281.—Paraffin has been oxidized to acids by nascent O in the presence of catalysts. The lower the m. p. of the paraffin, the easier the oxidation. The app. and conditions of the expt. are described. V. F. HARRINGTON

What determines the value of absorption oil? F. L. KALLAM. *Chem. Met. Eng.* **38**, 78–81(1931).—The phys. characteristics of 24 new oils and 34 used oils in use as absorption oils in various refineries are presented in the form of curves to show the predominating properties which det. the suitability of a given oil for this purpose. It is concluded that the mol. wt. of the oil should be of the order of 150 to 200. The av. b. p. of a proposed absorbent should be specified because it is the index of the initial b. p., the vapor pressure and the gravity. Max. distn. residuum or the demulsibility factor, freedom from wax sepn. at the lowest operating temp. and viscosity should also be included in absorption-oil specifications. D. F. BROWN

Notes on the viscosity-temperature relations of lubricating oils. W. L. BAILLIE. *J. Inst. Petroleum Tech.* **16**, 643–60(1930).—By calcns. from data in Archbutt and Deeley's *Lubrication and Lubricants*, it was shown that Eckart's formula for the relation of temp. to viscosity is as accurate for kinematic as for abs. viscosity. Results calcd. by it agree with exptl. results within about ±2.5%. It is a special case of the general formula given by Slotte, $V = b/(t + a)^n$, in which t is temp. and V is kinematic viscosity. An equation was derived relating efflux time in sec. in the Redwood viscometer to viscosity: $AT - B/T = w\theta^n$. A and B are consts. of the instrument, w and n, of the oil; T is time of efflux; θ is the temp. Rigorous temp. control is most important with viscous oils. A temp. variation of 0.14°F. may cause a change of 1% in viscosity. A table is given for conversion of Redwood seconds to kinematic viscosity EMMA E. CRANDAL

Inorganic lubricants. IV. Lubricants for temperatures above and below normal. WILLIS A. BOUGHTON. *J. Am. Chem. Soc.* **52**, 4858–60(1930); cf. *C. A.* **25**, 196.—Aq. solns. of HPO_3 and $NaPO_3$, mixts. of salts melted in their water of crystn. with an inert material such as kaolin or graphite and solns. of $Ca(NO_3)_2$ in melted KNO_3 are good lubricants at temps. both above and below ordinary. A lower limit of —75° and an upper one of 360° have been reached. EMMA E. CRANDAL

Amount of lubricating oil burned in the gasoline engine. CLARKE C. MINTER AND WM. J. FINN. *Ind. Eng. Chem.* **23**, 285(1931).—The amt. of oil burned in a gasoline engine was detd. by operating with H and analyzing the exhaust gases. L. W. T. C.

Effect of carbon black on insulating oils. W. B. WIEGAND, C. R. BOGGS AND D. W. KITCHIN. *Ind. Eng. Chem.* **23**, 273–6(1931).—The elec. properties of insulating oils are improved by treatment with C black. L. W. T. CUMMINGS

Improving petroleum asphalts. A. I. VORONOV AND N. I. LOGVINOVA. *J. Petroleum Ind.* **1930**, 439 (in Russian); *Asphalt u. Teer* **33**, 876–8(1930) (in German).—Still residues of low-resin and high-paraffin content may be converted into satisfactory asphalts by *vacuum distn.*, followed by the customary air blowing. Asphalts of the

naphthene-aromatic type, rich in desirable resins but deficient in asphaltenes, should not be blown. Blending these asphalts with asphalts of the Me-naphthene-aromatic type is more economical, and yields a technically superior product. K. H. ENGEL

Determination of asphaltene content. F. J. NELLENSTEIN AND N. M. ROODENBURG. *Chem.-Ztg.* **54**, 819(1930).—As a solvent for use in detg. asphaltenes, Et_2O is superior to normal benzine because it is a homogeneous substance not requiring standardization; its flocculating properties are combined with low surface tension; and it has a greater dissolving power for the hydroxy acids in asphalts produced by oxidation and for certain constituents of coal tar. R. E. SCHAAD

Separation of bitumen from bituminous sands. K. A. CLARK. *Nature* **127**, 199 (1931); cf. *C. A.* **24**, 2873.—The bitumen sepd. by means of solns. of Na_2SiO_3 contained 1–4% of mineral matter. Difficulties to duplicate results were encountered. Improvements were obtained by giving the sand a preliminary wash with cold H_2O and then treating with alkali to bring the p_H value up to 6.4. The water removes a part of the clay and reduces the necessary quantity of alkali. The acidity of the sand is considered to be due to the presence of Fe^{++} and Fe^{+++} salts carried into the beds by ground water. I. M. LEVINE

The estimation of wax in pitch. W. LITTLEJOHN AND W. H. THOMAS. *J. Inst. Petroleum Tech.* **16**, 814–24(1930).—As the outcome of a study of what factors must be controlled in order to get results approaching reproducibility for the % of wax in pitch, a cracking method is recommended. The pitch is distd., at the rate of 40–50° temp. rise per min. to 450°. Distn. is continued to 500° at 15° rise per min. The distillate is dissolved in pure Me_2CO in the proportion of 35 cc. per g., and the washings from the neck of the flask are added. The soln. is cooled to 0°F.; this ppts. the wax, which is filtered off, redissolved in 70 g. of acetone per g and repptd. at 32°F. E. E. C.

Chemical properties and examination of tar and pitches. BOCKSHAMMER. *Teer u Bitumen* **29**, 29–32(1931).—A set of tests has been arranged which allows the general characterization of unknown bituminous materials through the identification of typical components. K. H. ENGEL

Combustion and detonation in gaseous mixtures. Antidetonants (LAFFITTE) **24**. The analytical distillation of gasoline (TORMEY) **2**. The relative merits of gas, oil and electricity for industrial purposes (HOPKINSON) **13**. Critical solution temperatures of systems of SO_2 and normal paraffins (SEYER, TODD) **2**. Calculating viscosity and flash point in compounded oils (KADMER) **2**. Recovering oil from waste water (Swiss pat 140,639) **14**. Oil filter (U. S. pat. 1,792,854) **1**. Unactivated "prefiltering medium" for treating oils (U. S. pat. 1,794,862) **1**. Apparatus for extractions with liquid solvents (U. S. pat. 1,794,874) **1**. Rotary impeller agitating device and filter for treating oils (U. S. pat. 1,794,916) **1**. Separator for oil and water (Ger. pat. 517,425) **1**. Distillation of volatile substances [in refining oils] (Ger. pat. 514,740) **13**. Apparatus for "neutralizing" gases from gasoline engines (U. S. pat. 1,793,813) **1**.

Treating residues obtained on sweetening petroleum distillates. HERBERT G. M. FISCHER (to Standard Oil Development Co.). U. S. 1,795,278, March 3. Residue oil contg. alkyl polysulfides and obtained by the contact of sour petroleum distillates with S in the presence of a catalyst followed by distn. under reduced pressure to produce a sweetened distillate and a residue oil is heated to above 175° in order to reduce its S content. App. is described

Removing corrosive sulfur compounds from petroleum. WARREN F. BLEECKER U. S. 1,794,668, March 3. Brine is electrolyzed in the presence of the petroleum to produce Cl and H, and the nascent Cl is allowed to pass directly into the petroleum while the H is separately removed without introducing it into the petroleum. App. is described.

Purifying cracked petroleum vapors. CORNELIUS B. WATSON and RUDOLPH C. OSTERSTROM (to Pure Oil Co.). U. S. 1,793,885, Feb. 24. Vapors from a cracking process are cooled sufficiently to arrest conversion reactions, liquefied oil is sepd., remaining vapors are passed to a fractionating zone into the upper portion of which a material such as fuller's earth is introduced so that it falls countercurrentwise through the vapors, and vapors passing from this zone are further treated with fuller's earth or the like before passing to a sepg. zone. An arrangement of app. and various details of operation are described. Cf. *C. A.* **24**, 489.

Apparatus (with a tank and internal pipe coil) for cracking petroleum oils. ARTHUR

E. Pew, Jr. and Henry Thomas (to Sun Oil Co.). U. S. 1,794,200, Feb. 24. **Structural details.**

Cracking petroleum oils. Lyman C. Huff (to Universal Oil Products Co.). U. S. 1,793,443, Feb. 17. In a process such as that in which the oil is heated while passing through a pipe coil and thence introduced into a reaction and sepg. chamber, any accumulation of unvaporized liquid oil in the reaction zone is prevented by continuously and rapidly withdrawing the liquid from the reaction zone, while maintaining both the heating zone and reaction zone under superatm. pressure. Cf. *C. A.* **24**, 410.

Cracking hydrocarbons. O. D. Lucas. Brit. 336,269, April 10, 1929. See Fr. 692,549 (*C. A.* **25**, 1666).

Cracking hydrocarbons. Panhandle Refining Co. Brit. 337,380, June 29, 1929. See Fr. 678,412 (*C. A.* **24**, 3637).

Distilling hydrocarbons such as petroleum, tar or coal. Emil Piron. U. S. 1,794,542, March 3. A layer of the material is applied to a moving surface such as a heated chain or conveyor which is conducted through a distn. zone to effect distn. under heating and the distn. is positively checked by adding a further layer prior to removal of the residue from the distn. chamber (to avoid over-cracking). App. is described. Cf. *C. A.* **24**, 490.

Distilling hydrocarbon oils such as petroleum. John E. Bell (to Sinclair Refining Co.). U. S. 1,795,070, March 3. Vapors of the oil are passed from a still to a refluxing tower and uncondensed vapors from the latter are brought into indirect heat-exchange relation with fresh oil to preheat the oil and cool the vapors; the preheated fresh oil is introduced into the tower at a point below the point of introduction of vapors from the fresh oil into the tower, and addnl. oil is introduced into the reflux tower at a still higher point than the fresh oil vapors. App. is described. Cf. *C. A.* **24**, 1211.

Fuel from petroleum distillation residue. Richard L. Rodgers U. S. 1,793,014, Feb. 17. Residue from petroleum distn. or cracking, in finely divided form, is mixed with a substantially neutral liquid petroleum deriv. such as residuum oil or crude petroleum and a batch of this mixt. is heated at a carbonizing temp. to form a solid, coherent fuel.

Converting hydrocarbon material into products of lower boiling point. Wm. Landes. U. S. 1,792,912, Feb. 17. Various details of app. are described including a heating coil, expansion chamber and superheated steam supply.

Converting heavy hydrocarbon oils into products of lower boiling point. Jay J. Jakowsky (to C and C Developing Co.). U. S. 1,792,744, Feb. 17. A relatively heavy oil is vaporized under conditions such that a substantial part of the resultant vapors is in non-gaseous and substantially satd. condition, and the vapors, while in operative proximity to a surface heated to a converting temp. substantially above that of vaporization, are subjected to the pptg. action of a high-tension silent elec. discharge tending to drive the non-gaseous portion of the vapors toward the heated surface, and uncondensed products are conducted away for recovery of a desired product of lower b. p. App. is described. Cf. *C. A.* **25**, 200.

Refined white viscous hydrocarbon oil. Thomas H. Rogers (to Standard Oil Co. of Ind.). U. S. 1,793,134, Feb. 17. A small proportion of a naphthol is added for preventing acid formation and increase of emulsifiability in use of highly refined viscous hydrocarbon oils such as those used for lubricating turbines. U. S. 1,793,135 specifies the addn. of about 0.04% of pyrogallol for the same purpose, and refers to the use generally of similar polyhydroxy aromatic compds. Cf. *C. A.* **24**, 5149.

Separation of unsaturated constituents from hydrocarbon oils. Wm. M. Stratford (to Texas Co.). U. S. 1,792,877, Feb. 17. Material such as products from a cracking still in vapor form is continually brought into contact with a bed of adsorbent catalytic material such as fuller's earth, and adsorbed polymers are intermittently washed from the catalytic bed by the supply of solvent such as kerosene. App. is described. Cf. *C. A.* **24**, 4928.

Apparatus for separating oil and gas. Jay P. Walker (40% to Guy O. Marchant and 6% to C. G. Wells). U. S. reissue 17,983, Feb. 24. Reissue of original pat. No. 1,661,685 (*C. A.* **22**, 1470).

Modifying mineral oils. L. Auer. Brit. 337,751, April 24, 1929. Mineral oils are modified to produce viscous oils or thin gels suitable for use as lubricants by admixt. with them, while heated, of greatly modified fats, fatty oils or resin products which may be prepd. by heating *in vacuo* with reagents such as amines (as described in Brit. 317,732, *C. A.* **25**, 2312) or with compds. such as benzenesulfonic acid (as described in Brit. 321,724, *C. A.* **24**, 2904) or with compds. such as Li sulfite (as described in Brit. 321,725, *C. A.* **24**, 2904) or with saponaceous compds. (as described in Brit.

321,691, *C. A.* **24**, 2910; and in Brit. 321,723, *C. A.* **24**, 2911, but with a larger proportion of modifying agent than used in the previously described processes), or by use of a product formed by treating an aq. soln. of salts of amines such as benzidine or dianisidine with a soap soln. of high-mol. org. acids such as the NH_4 soap or linseed oil fatty acids.

Refining mineral oils. AXTELL RESEARCH LABORATORIES, INC. Ger. 517,196, Dec. 22, 1927. See Brit. 282,738 (*C. A.* **22**, 3984).

Refining mineral oils. GRIGORI PETROFF. Ger. 517,197, Jan. 18, 1927. A fat or a fatty acid, *e. g.*, stearic or oleic acid, is added to mineral oils before refining them by means of concd. or fuming H_2SO_4. Examples are given.

Storage tank and breather system for storing mineral oils and gas. WILBUR G. LAIRD (to Doherty Research Co.). U. S. 1,794,383, March 3. Structural features.

Heating oil to cracking temperature and superheating steam. JOHN PRIMROSE (to Foster Wheeler Corp.). U. S. 1,792,925, Feb. 17. Oil is passed serially through a portion of a heating tube bank absorbing radiant heat in a combustion chamber from a horizontally disposed tube bank in a second chamber partly sepd. from the combustion chamber, at a velocity high enough at least substantially to avoid cracking of the oil being heated, and heating gases are contacted with the tube system at such temp. and volume that they may be subsequently used for superheating steam to about 480° or higher. App. is described.

Oil-still operation. BENJAMIN BROIDO (to Superheater Co.). U. S. 1,794,439, March 3. Viscous material such as heavy petroleum has its viscosity reduced rapidly by heating with a heating medium such as furnace gases while the latter is at a high temp. and transfer of heat from the heating medium to the liquid is completed under counterflow conditions without permitting any vapors to sep. from the liquid during the second heating; gaseous products are removed from the liquid after the initial heating and are added to the liquid at the end of the second heating. An app. is described comprising pipe coils in a furnace setting.

Distilling oils in vacuo. R. R. COLLINS. Brit. 337,545, Oct. 11, 1928. Distn. such as that of a heavy cylinder oil mixed with wax distillate is effected *in vacuo* by spraying in several zones across the rising vapors of the liquid in a column, collecting liquid in peripheral troughs, and recirculating in each zone by sep. pumps. Various details of app. are described.

Recovery of oils from mixtures such as destructive hydrogenization products of brown coal. MATHIAS PIER, RUDOLF WIETZEL and BRUNO ENGEL (to I. G. Farbenind. A.-G.). U. S. 1,794,865, March 3. Mixts. such as sludges and residues contg. oils and free C are centrifuged with an addn. of liquid aromatic hydrocarbons such as benzene possessing good solvent properties for the oil. Na isopropylnaphthalenesulfonate also may be added.

Destructive hydrogenation. J. M. JENNINGS (to Standard Oil Development Co.). Brit. 337,671, Dec. 21, 1928. In destructive hydrogenation of heavy fluid materials such as crude oils, tars, cracked residues or suspensions of coal in oils, by use of solid catalysts immune to poisoning from S, such as Cr or Mo oxides, the ratio of asphalt to catalyst in the material treated is kept below 1.5 and preferably below 0.5, in order to prevent coking. Various details of temps. and pressures and construction of app. used, etc., are given. Cf. *C. A.* **25**, 580.

Destructive hydrogenation. W. R. TATE, H. P. STEPHENSON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 338,150, Aug. 13, 1929. In destructive hydrogenation of carbonaceous liquids such as oils or suspensions of coal in oils, a vertical reaction vessel and a vessel for the sepn. of liquid and vaporous products are housed in the same high-pressure vessel, and the separator is maintained at a temp. lower than that of the reaction vessel by using the reaction products to preheat the liquids or gaseous materials or both. The entering H may be divided into 2 streams, one of which is heated by an elec. heater and the other of which is preliminarily used to cool the reaction products and then passed to the heater. Numerous details of construction and operation of the app. are described.

Freeing oils and tars from suspended solids. I. G. FARBENIND. A.-G. Brit. 338,154, May 14, 1929. Oils and tars such as those obtained by destructive hydrogenation are freed from suspended solids by treatment with gases acid to wet litmus such as SO_2 or CO_2 and then filtering or centrifuging. A thinner such as benzine may be added and CO_2 may be bubbled through tar at a temp. of 90°.

Producing and refining cracked gasoline. FRANK A. APGAR (to Sinclair Refining Co.). U. S. 1,795,067, March 3. Raw vapor mixt. from a cracking operation is scrubbed for sepn. of unvaporized oil, tar and tarry matter, an oil condensate of higher b. p.

than gasoline is sepd. from the raw vapor mixt. discharged from the scrubbing operation before the vapor mixt., including the gasoline vapors, is passed through an adsorbent catalyst such as fuller's earth for refining, and oil condensate thus sepd. is then passed through the adsorptive catalyst together with the vapor mixt. including the gasoline vapors, to serve as a liquid washing agent, and the washing agent and assocd. polymers from the last-mentioned step are sepd. from the refined vapor mixt. and are led directly to the scrubber. An arrangement of app. is described. Cf. *C. A.* **24**, 718.

Refining gasoline. EUGENE C. HERTHEL (to Sinclair Refining Co.). U. S. 1,795,124, March 3. Vapors of gasoline to be refined, together with vapors of higher b. p. hydrocarbons in such proportion that the vapor mixt. when condensed forms a condensate contg. not less than about 50% and not more than about 75% of the gasoline product, is passed first through a condensing operation in which a part of the higher b. p. hydrocarbons is condensed, and the total vapor mixt. and condensate are then passed through an adsorptive catalyst and thereafter the constituents of higher b. p. than are suitable for inclusion in the final gasoline product are sepd. and the remaining vapors are then condensed as the refined gasoline. An arrangement of app. is described.

Filter for gasoline, etc. A. G. FENN and ANGLO-AMERICAN OIL CO., LTD. Brit. 337,539, Sept. 27, 1929. Structural features

Filter for oil or gasoline suitable for use on motor vehicles. SIDNEY L. WOLFSON (to Cuno Engineering Corp.). U. S. 1,792,791, Feb. 17. Structural features.

Decolorizing material. WALTER S. BAYLIS (to Filtrol Co. of Calif.). U. S. 1,792,625, Feb. 17. A decolorizing clay is heated sufficiently to remove all free water and also water of crystn. and then mixed with 4–8% anhyd. H_2SO_4. The product is suitable for treating gasoline.

Method and plant for separating waxy and fatty substances from oils, particularly paraffin from mineral oil, by cooling. THE SHARPLES SPECIALTY CO. Ger. 517,198, July 25, 1925. This corresponds to Brit. 261,450 (*C. A.* **21**, 3455).

Paraffin wax. I. G. FARBENIND. A.-G. (Berthold Ottens and Martin Müller-Cunradi, inventors). Ger. 517,280, Apr. 18, 1929. To remove oil from crude paraffin wax, the latter is centrifuged while gradually warming it up to the m. p. of the pure wax.

Immersion wax. FREDERICK W. SULLIVAN, JR. (to The Standard Oil Co.). Can. 308,755, Feb. 17, 1931. A immersion bath for heat treating molded articles comprises a paraffin wax and from about 0.05–0.5% of an org. aromatic compd. of the class including β-naphthol, pyrogallol, diphenylamine, gallic acid, hydroquinone and p-$C_6H_4(NH_2)_2$. This additive substance inhibits the rapid formation of excessive acidity and prolongs the life of the bath.

Apparatus for determining the friction coefficient of lubricating oils, etc. YACCO S. A. F. Ger. 517,211, July 3, 1928. See Brit. 305,242 (*C. A.* **23**, 4599).

Thickening lubricating, insulating or other oils. I. G. FARBENIND. A.-G. Brit. 337,639, Nov. 29, 1928. The viscosity of oils such as castor oil, whale oil or transformer oil is increased by adding esters, ethers, mixed esters or ether esters of carbohydrates such as those of starch or cellulose, *e. g.*, triethylcellulose, cellulose naphthenate or the like.

Purifying used lubricating oils. PRESTON, STALLARD & CO., LTD., and J. MALSBURY. Brit. 337,981-2, Nov. 8, 1929. Various details are described of an app. suitable for use in purification processes such as described in Brit. 306,771 (*C. A.* **23**, 5314).

Refining used crank case oil. RUDOLF A. WISCHIN. U. S. 1,792,882, Feb. 17. The oil is intimately mixed with cold concd. H_2SO_4 and then gradually heated in the course of several hrs. to about 50–60°, sludge is sepd., suspended solid matter is removed, and steam is injected into the mixt. App. is described.

Emulsifying asphalt. ROBERT K. PAINTER (to Bitutect, Inc.). U. S. 1,793,957, Feb. 24 Asphalt is dissolved in a solvent such as CCl_4 and there is added to the soln. an aq. soln. of colloidal clay, the solid content of which is less than 2% of the emulsion produced; the mixt. is agitated (suitably at a temp. of about 55°) and addns. of an org. acid such as HOAc are made to maintain a desired acidity, and the asphalt is pptd. in the presence of the colloidal soln. and at the proper degree of acidity. App. is described.

Aqueous dispersions of water-insoluble materials such as asphalt. JACOB M. FAIN (to Flintkote Co.). U. S. 1,793,918, Feb. 24. In producing aq. dispersions of material such as asphalt contg. less than 2% as much of a dispersing agent such as bentonite and soap or saponin, an aq. suspension is made of paste-forming colloidal material such as bentonite and the suspension is modified by adding to it an agent such as soap of such character and quantity as to reduce the surface tension of the aq. medium

and facilitate dispersion with light agitation, and the water-immiscible material is mixed with and dispersed in this suspension.

Bituminous emulsions. LEON R. MACKENZIE. U. S. 1,795,226, March 3. Molten bitumen and an emulsifer are flowed together directly at a combining temp. only slightly below the b. p. of the emulsifier, to form an emulsion with the bitumen as the external phase, and the emulsion is then immediately removed from the zone of formation and is agitated to reverse the phases of the emulsion. App. is described.

Bitumen. ANDREI MANBA. Ger. 517,166, Aug. 11, 1926. A ductile bitumen is prepd. by treating bituminous distn. residues at about 250° with a mixt. of H_2SO_4 and so much S that the H_2SO_4 is completely decompd. in the reaction. The process may be modified by treating the distn. residues with H_2SO_4, sepg. the tarry ppt., adding to this the necessary amt. of S, and heating to about 250°.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Cellulose from sugar. V. N. IPAT'EV. *Compt. rend. acad. sci. U. R. S. S.* 1930A, 381.—Five g. of cellulosic material obtained from monosaccharides was analyzed. The cellulosic material proved to be sol. in Schweitzer reagent and did not reduce Fehling soln.; it is seen to be cryst. in a polarization microscope, and it hydrolyzes if heated with H_2SO_4. L. JACOOVLEFF

X-ray studies of cellulose derivatives. VIII. The alkali celluloses. KURT HESS AND CARL TROGUS. *Z. physik Chem.*, Abt. B, 11, 381–408(1931).—The x-ray fiber diagram of natural cellulose disappears in fibers treated with NaOH-H_2O solns. Two new fiber diagrams are obtained, one characteristic of Na cellulose I, formed in solns. contg. up to 19% NaOH by wt., and the other characteristic of Na cellulose II, formed in solns. contg. 21% or more NaOH. Drying Na cellulose II produces no change in its fiber diagram, but a new fiber diagram corresponding to an anhyd. Na cellulose III is obtained from dried fibers of Na cellulose I. Calcd. fiber periods are: Na cellulose I, 10.4 ± 0.2 A. U.; Na cellulose II, 15.1 ± 0.2 A. U.; Na cellulose III, 10.2 ± 0.2 A. U. Na cellulose I is considered responsible for the phenomenon of swelling since the greatest swelling of fibers is produced by 14.5–15% NaOH soln. Washing unstretched Na cellulose I or II with water forms a fiber giving the diagram of cellulose hydrate; by washing stretched, the diagram of natural cellulose is also obtained. Washing Na cellulose I with CH_3OH produces decompn.: Na cellulose II changes to Na cellulose I. Several weeks' action of NaOH-CH_3OH solns. on cellulose forms Na cellulose III or Na cellulose II; if water is added, Na cellulose I or Na cellulose II are formed quickly. Sharp fiber diagrams are obtained for K cellulose (fiber period 10.2 ± 0.2 A. U.) formed by the action of 18.5% KOH soln. on cellulose, and for Li cellulose (fiber period 10.4 ± 0.2 A. U.) formed by the action of 10.9% LiOH soln. Other forms of Li and K celluloses will be described later. JANET E. AUSTIN

Fatty acid-nitrocellulose mixed esters. HANNS SCHMIDT. *Nitrocellulose* 2, 4–6 (1931).—A review of patents. E. M. SYMMES

A study of some properties of nitrocellulose made from jute with special reference to its stability. RAMESH CHANDRA BAGCHI. *J. Indian Chem. Soc.* 7, 863–74(1931). The amt. of stabilization necessary increases with the content of impurities. Washing with dil. acid alone is not sufficient but must be followed by neutral or alk. washing. Alc. is a very effective washing agent for improving stability. Very small quantities of easily hydrolyzable pentosans and hexosans, or degraded cellulose from the action of concd. alkali, will give unstable products. The N content of the nitrocellulose decreases as impurities increase. Unless the jute is carefully purified uniform nitration is more difficult than with cotton. The Et_2O-alc. soln. of jute nitrocellulose is much less viscous than that of cotton; this indicates that the 2 celluloses are not identical. FOSTER DEE SNELL

Tentative standard method for the determination of α-cellulose. WM. R. WILLETS. *Paper Trade J.* 92, 117(1931).—The procedure is essentially that of Method IV of the Am. Chem. Soc. (Ritter, *C. A.* 23, 5569), with the following minor modifications: (1) The use of 95% EtOH or MeOH followed by petr. ether or other non-reacting volatile liquid for washing the α-cellulose after the final treatment with hot water is recommended to facilitate drying. (2) The detn. of residual lignin (by the Madison Forest Products Lab. method) in the α-cellulose is recommended for unbleached pulps. A. PAPINEAU-COUTURE

Extending knowledge of cellulose and lignin. HAROLD HIBBERT. *Research Notes* **3**, 37–8(1930); *Pulp Paper Mag. Can.* 31, 326–7(1931).—A brief review is given of the work during 1930 at the Dept. of Industrial and Cellulose Chemistry, McGill Univ., Montreal. A. PAPINEAU-COUTURE

Alkylbeechwood lignins and their cleavage. ANTON VON WACEK. *Ber.* **63B**, 2984–93(1930); cf. *C. A.* **24**, 2878.—It was reported in the earlier paper that cleavage of a primary beechwood methyllignin with alc. NaOEt gives an oil consisting of a neutral and an acid portion, the former of which gives 3,5-$(MeO)_2C_6H_3CO_2H$ (I) on oxidation. It was believed that the acid portion contained a pyrogallol deriv. Such a product, contg. a free phenolic group, could be oxidized only after complete etherification, and in order to be able to distinguish the alkyl group introduced after the cleavage from that already present in the cleavage product the acid oil was ethylated and then oxidized. It did not yield a gallic acid deriv. as expected, but 3,4-$MeO(EtO)C_6H_3CO_2H$ (II). Methylbeechwood lignin therefore gives as cleavage products 3,5-$(MeO)_2C_6H_2C$- and 4,3 $HO(MeO)C_6H_2C$-. To det. whether the MeO groups are present in the original lignin or are introduced during the methylation, the lignin was ethylated before the cleavage. As the prepn of the primary methyllignin from the methylwood requires an enormous excess of alkylating agent, expts. were carried out to det. if a product of as high a MeO content could be prepd. more cheaply from isolated lignin, and also if such a lignin could be made to take up a corresponding amt. of EtO instead of MeO. The lignin (max. MeO content 21.8%), prepd. by Freudenberg's method, gave on repeated methylation a product with 36.57% MeO, the ratio of the original to the newly introduced MeO being 100:81.1. The ratio is higher than that assumed in the earlier paper for the primary methyllignin, but when the product is treated by Friedrich's method only about 25% dissolves and the lignin pptd. from the Me_2CO contains only 32.59% MeO. The Freudenberg lignin, ethylated 8 times at 60°, gave a product with 19.01% EtO, the total alkoxy content (calcd. as the MeO of a methylated substance) being 34.17%, *i. e.*, less than after an equal no. of methylations. Cleavage of the methylated Freudenberg lignin under pressure gave a neutral and an acid product; the latter (after ethylation) yielded II on oxidation, but the neutral oil gave an acid which, to be sure, sublimed *in vacuo* but began to brown only above 240°, did not m. 300° and certainly was not I. The "rest" lignin, therefore, here too differs from the extd. primary methyllignin. It would seem as if a part of the lignin is more easily dissolved. In the hydrolysis by Friedrich's method, this part is not lost, but CuO-NH_4OH dissolves it along with the cellulose, leaving behind the insol. Freudenberg lignin, which behaves differently from the primary lignin. For a comparison of the cleavage of an ethyllignin with that of the primary methyllignin, it therefore became necessary to start from a primary ethyllignin also, which was prepd. from deresinified and degummed beechwood meal with Et_2SO_4. Fourteen ethylations at 60° gave a product with a const. alkoxy content of 27.35% (calcd. as MeO); with an original MeO content of 6% in the degummed wood, this corresponds to a 30.46% MeO content of a methylated beechwood, while the MeO value of beechwood meal exhaustively methylated was 39.1%. The primary ethyllignin obtained by Friedrich's method from this ethylwood contained 29.10% alkoxy (calcd. as MeO); with a 20.5% MeO content of the primary lignin (extd. with Me_2CO), this corresponds to a 30.56% MeO content of a primary methyllignin, as compared with 33.6–35.2% obtained in the isolation from methylwood. The ethylwood prepd. at this temp. and the primary ethyllignin obtained from it were very sensitive and carbonized if heated higher than 70° *in vacuo;* cleavage with alc. NaOEt under pressure gave an oil almost completely sol. in Et_2O, part of which $b_{0.5-1}$ 160–70°; on oxidation the neutral part gave only a trace of cryst. products, the acid part none at all. The ethylation was accordingly repeated at a lower temp. (25–30°); 12 treatments gave an ethylbeechwood with 30.15% alkoxy (calcd. as MeO), corresponding, with an original 5.77% MeO content of the deresinified and degummed wood meal, to a 37.34% EtO content and a 34.12% MeO content of methylated wood. Considerably more EtO can therefore be introduced by cold ethylation than at the higher temp., although the alkoxy content is still considerably less than can be obtained by methylation. The cold ethylated wood and the primary ethyllignin obtained from it according to Friedrich do not show the sensitivity of the products obtained by ethylating at 60°. The primary ethyllignin contains 31.27% alkoxy (calcd. as MeO), corresponding to 19.19% EtO and 33.26% MeO of methylated lignin. Cleavage with NaOEt under pressure gives an oil sol. in Et_2O and in part $b_{0.5-1}$ 215°; the neutral part gives with $KMnO_4$ a little I, but the acid part, after methylation, gives no cryst. products. The EtO groups could not be detected in the phenolic cleavage products. These results indicate that there is no free phenol group in the phenolic

units of genuine beechwood lignin but that there are other alkylatable groups. The MeO groups found in the cleavage products are already present in genuine lignin. The 2 cleavage fragments identified probably originate, in part, at least, from a common unit, $—OC_6H_2(OMe)_2C—$, but the MeO content of the isolated lignin and methyllignin is not in harmony with the assumption that the lignin consists only of a chain of the units $—OC_6H_3(OMe)_2CH_2CH:CH—$. C. A. R.

Recent advances in the chemistry of cellulose in relation to pulp and paper. C. J. J. Fox. *World's Paper Trade Rev.* 95, 374, 376, 420, 422, 462, 464, 518, 520(1931).—An address dealing with recent investigations on the chemistry and physics of cellulose, particularly as regards its structure. A. Papineau-Couture

Report of the committee on chemical and physical standards. H. O. Keay. *Pulp Paper Mag. Can.* 31, 185–8(1931).—The present methods of prepg. sheets for testing the initial strength of paper pulp prevailing in North America and in Europe are reviewed. The disintegration of the pulp, the formation of the sheet, couching, pressing, drying and conditioning are discussed. The comm. considers that the best means yet devised for the formation of the test sheet is the Brit. sheet machine; that the couching of the sheet should be done by means which eliminate the influence of the operator, which is probably best obtained by the use of a couch plate together with a roll of fixed wt. as adopted by the Brit. comm. on evaluation of paper pulp; that the work of Cameron and his co-workers (*C. A.* 21, 1350) has shown that 200 lb. per sq. in. is most satisfactory for pressing the sheets; and that the procedure of the Brit. Assocn. for drying the sheets, though more elaborate, is justified because it eliminates the uncertainty which results from shrinkage when the sheet is not dried under tension. It is felt that as yet insufficient data have been accumulated to warrant definite recommendations. A. Papineau-Couture

The determination of the strength of pulps. K. G. Jonas. *World's Paper Trade Rev.* 95, 466, 468, 510–6(1931); cf. *C. A.* 25, 1074.—In order that detns. of the strength of pulp may be of value, it is essential to have a beating method and a sheet-forming method, each giving reproducible results. The ideal exptl. beater should fulfil the following conditions: it must (1) work reproducibly, (2) allow of a beating effect as nearly as possible corresponding to that of the beater in practice, (3) make possible the working out of a complete beating curve without a great consumption of time (4) permit variation of and exact regulation of the beating pressure. These requirements are claimed to be met by a lab. beater devised by J. and Kross. Six cylindrical beating containers are symmetrically arranged around the axis of a disk to which they are firmly but rotatably attached; they are closed by means of covers fitted with packing rings, each cover carrying a toothed wheel which engages with a similar wheel keyed on a fixed central shaft, so that when the machine is running each container rotates about the central shaft and about its own axis. In each container is a beating roll consisting of a free massive cylinder, in whose surface a series of half round (6 mm diam.) flutes are milled so that a tooth 2 mm. wide remains between adjacent flutings. The beating pressure is regulated by adjusting the speed of rotation. The equiv. of 11.2 g. of oven-dry pulp is weighed into each beating container, the calcd. quantity of water (preferably to a consistency of 6%) is added, the material is softened by allowing it to stand exactly 30 min. and is then disintegrated by running for 10 min. at 10 r. p. m.; beating is then carried out by running at a suitable speed (150 r. p. m. or more) so as to obtain a complete beating curve within 1 hr., the containers being successively removed at stated intervals and replaced by empty containers of the same wt. A test sheet-forming machine is also described, which is claimed to give very even formation and reproducible results, the variations in the strength of sheets made from the same pulp and beaten to the same degree being from 2–3 times as great with the Schopper sheet-former as with the Jonas-Kross app. J. found that the highest breaking length was obtained with sheets weighing 90–2 g. per sq. m., and suggests that this wt. should therefore be adopted. A. Papineau-Couture

Some factors affecting the strength of groundwood. A. Ruby. *Papier* 33, 1283–1300(1930).—A review is given of the effects of the species of wood, conditions of growth, age, dryness and state of preservation of the wood, barking, nature, dressing and speed of the stone, grinding pressure and temp., screening and refining of the groundwood and conditions of storing. A. Papineau-Couture

Studies in the manufacture of groundwood pulp. H. Wyatt Johnston. *Pulp Paper Mag. Can.* 31, 221–32(1931).—An analysis is given of the program for investigation of groundwood manuf. at the Montreal Forest Products Labs. A. P.-C.

Practice and control of beating and jordaning. F. W. Motschman. *Paper Trade J.* 92, No. 8, 127, 129(1931).—Experiences and opinions concerning the manipulation of

beater rolls and measurement of power consumption and indices of hydration. Particular attention is given to types of jordan filler to make sp. grades of paper. A. P.-C.

Bibliography of wood-pulp strength testing. DONALD E. CABLE. *Paper Trade J.* **92**, No. 9, 35-9(1931).—This is a continuation of Moore's bibliography (*C. A.* **23**, 5580) and comprises abstracts of 27 articles published in 1929 and 1930. A. P.-C.

Tests on cotton and wood pulp for nitrocellulose plants. M. STEUDE. *Nitrocellulose* **2**, 10–11(1931); cf. *C. A.* **25**, 413.—Methods of detn. of Cu no., degree of bleaching, neutral gum, hemicellulose, albumen, absorptive power and viscosity are given. E. M. SYMMES

Instruments for determining the freeness or degree of beating of paper pulps. LOUIS SCHOPPER LABORATORIES. *Papier* **33**, 1303–19(1930).—The construction and method of using the latest type of Schopper-Riegler freeness tester are described. A. PAPINEAU-COUTURE

Hard facing in the pulp and paper industry. W. A. WISSLER. *Paper Trade J.* **92**, No. 8, 137-43(1931).—A discussion is given of the merits of hard-facing of equipment parts subjected to wear in various applications in the pulp and paper industry. The different types of hard-facing materials are indicated, together with their fields of application and the method of applying them to the parts to be faced. A. P.-C.

Instrument applications in pulp and paper mills cut costs and safeguard profits. REGINALD TRAUTSCHOLD. *Paper Trade J.* **92**, No. 2, 32-8; No. 4, 28–42(1931).—A general discussion is given of the importance of instruments in pulp and paper mill operation, where they make for economical operation by permitting of a satisfactory balance and coördination of all the many steps involved. A. PAPINEAU-COUTURE

The photoelectric tube in paper manufacture. S. A STAEGE. *Pulp Paper Mag. Can.* **31**, 315 6(1931).—A brief outline is given of some of the possible uses to which the photoelec. tube can be put in the manuf. of paper. A. PAPINEAU-COUTURE

Bibliography of paper making for 1930. C. J. WEST. *Paper Trade J.* **92**, No. 8, 145–85, No. 9, 40-6, No. 10, 47-54(1931).—A classified list is given of articles on pulp and paper making published in 1930. A PAPINEAU-COUTURE

United States patents on paper making: fourth quarter, 1930. C. J. WEST. *Paper Trade J.* **92**, No. 6, 61-2(1931); cf. *C. A.* **25**, 500.—A list in numerical sequence of U. S. pats. relating to pulp and paper manuf. issued during Oct., Nov. and Dec., 1930. A. PAPINEAU-COUTURE

Recent investigations of paper-making materials. ANON. *Bull. Imp. Inst.* **28**, 411-24(1930). *I. Soft wallaba wood (Eperua falcata) from British Guiana.*—The wood contained 55.3% cellulose on the dry basis, as compared with 39.7% in a sample analyzed some yrs previously (*C. A.* **22**, 3297). The difference in cellulose content is attributed to difference in age. Cooking with 20% NaOH on the wt. of the wood, at a concn. of 4%, for 5 hrs. at 160° yielded 46% of dry unbleached pulp and 40% of dry bleached pulp. This treatment gave a well-reduced pulp, which furnished a soft, opaque, rather bulky, brown paper, of fairly good strength, but containing a no. of very small pieces of undisintegrated fiber and small black specks. The pulp bleached fairly readily to a cream color, but the black specks were not eliminated. Increasing the cooking temp to 165° yielded 44% of dry unbleached pulp and 40% of dry bleached pulp, similar in quality to those obtained at 160°, but containing no specks. Kraft paper of fair quality, but lacking somewhat in strength, could be produced from the above pulp; but the wallaba fiber being very resistant to hydration, the cost of beating would be about twice as high as in the ordinary com. production of kraft paper. A sulfite pulping test carried out by cooking 100 g. of wood for 8 hrs. at 75 lb. and at a max. temp. of 158° (maintained for 7.4 hrs.), with 1000 cc. of liquor contg. 5.08% total and 3.48% free SO_2, yielded a gritty, resinous pulp showing very little felting power, which could not be made into sheets; this result is attributed to the high "resin" content (12% acetone-sol.). *II. Xerotes longifolia from Tasmania.*—The material, consisting of tough, rush-like stems and rather tightly rolled thin leaves, contained 4.2% ash and 41.1% cellulose (10% moisture basis). The fibers were 1.0–3.2 mm. long (av. 2.0), and 0.005–0.020 mm. in diam. (av. 0.012). Cooking 3 hrs. at 145° with 17.2% NaOH at a concn. of 3% yielded 40% dry unbleached pulp and 36% dry bleached pulp (bleach consumption 20%), but there remained numerous particles of brown, incompletely disintegrated material, even after bleaching. Increasing the NaOH to 21.5%, the time to 3.5 hrs. and the temp. to 150° gave 39 and 35% of unbleached and bleached pulps, resp. The unbleached pulp still contained a large no. of particles of imperfectly

digested material, most of which were removed on bleaching. The well beaten pulp yielded a tough, opaque paper of good strength, somewhat similar to that produced from esparto, but less bulky, harder and somewhat stronger. *III. Raupo leaves from New Zealand.*—Raupo leaves (*Typha angustifolia* Linn., var. *Brownii*) contained H_2O 12.7, ash 3.0, cellulose 38.3% (43.8% on dry basis); the fibers were 0.6–3.0 mm. long (av. 1.42) and 0.005–0.0177 mm. in diam. (av. 0.0076). Cooking 3 hrs. at 140° with 16% NaOH at a concn. of 3% yielded 32% of dry unbleached pulp and 29% of dry bleached pulp. The test produced a fairly well digested pulp, which furnished a pale brown, hard, rather rattly, opaque paper of good strength; this showed some shrinkage on drying and contained some imperfectly sepd. fibrous material, which was removed by bleaching. The yield is too low to make the material promising as a source of paper pulp; for the manuf. of rayon, the pitch would first have to be removed from the leaves, and this would still further reduce the yields. *IV. Reeds (Phragmites vulgaris) from northern Rhodesia.*—The material contained H_2O 7.5%, ash 1.9%, cellulose 50.0% (54.1% on the dry basis); the fibers were 0.8–3.0 mm. long (av. 1.7) and 0.0102–0.0508 mm. in diam. (av. 0.0193). Cooking 4 hrs. at 150° with 16% NaOH at a concn. of 4% yielded 47% dry unbleached pulp and 39% dry bleached pulp, similar to that furnished by esparto, yielding a fairly soft, bulky, opaque paper, but requiring nearly twice as much bleaching powder as esparto. *V. Sisal waste.*—Cooking 5 hrs. at 160° with 20% NaOH at a concn. of 4% yielded 44% of dry unbleached pulp and 42% of dry bleached pulp, which gave a tough, rather rattly, opaque paper of excellent strength but contg. numerous brown specks (consisting of cellular material) which were eliminated to a large extent on bleaching. A preliminary dusting treatment, which removed about 30% of non-fibrous matter, gave by the same treatment 53% dry unbleached pulp and 50% (equiv. to 35% on the original material) of dry bleached pulp. The unbleached pulp still contained a small amount of cellular material, which was easily eliminated on bleaching. The bleached pulp yielded a white paper of excellent strength and quality and practically free from specks. A. P.-C.

Testing of paper for water resistance. Philip W. Codwise. *Paper Trade J.* 92, No. 10, 55–7(1931).—The dry-indicator method offers the greatest promise of development to a universally acceptable standard test for the degree of total size resistance. Preliminary collaborative work having given results that were inconclusive and that indicated the necessity of further development work, the following points were studied: nature and prepn. of the indicator mixt., application of the indicator on the test sheet, reading of the end point, effects of humidity and temp. A technic embodying the results of the investigation is described in detail. A. Papineau-Couture

Porosity and air space of paper. James Strachan. *Paper Maker & Brit. Paper Trade J.* 81, No. 1, xli–xliii(Jan., 1931).—A general discussion is given of the subject defining the difference between porosity and air space, indicating the practical importance of the subject to paper users, outlining the methods of practical paper making adopted in controlling porosity and air space, and reviewing the methods of testing the porosity of paper. A. Papineau-Couture

Freeness testing. W. Boyd Campbell. *Research Notes* 3, 25-30(1930); *Pulp Paper Mag. Can.* 31, 264–7, 280(1931); cf. *C. A.* 24, 1976.—The principles underlying freeness testing of pulps are discussed and the conditions necessary for the operation of freeness testers are pointed out. The effect of the pressure head and the duration of flow in compacting the pulp are particularly stressed. A math. analysis is given which relates the freeness as detd. by the Can. freeness tester and the English sheet machine to the sp. resistance of the pulp to flow through it. For the Can. tester $R = 3044 (1000 - V)/V$; for the English sheet machine $R = 10.30\ tF/W$, where R is the resistance of 1 g. of pulp in a layer on 100 sq. cm., V is the vol. of outflow from the chamber at the end point of the test, t is the time of flow in sec., F is the fluidity of water in reciprocal centipoises, and W is the wt. of sheet formed. It is pointed out that R is different when detd. on the 2 machines and that the ratio of the 2 values is a measure of a pulp quality termed the compressibility. Exptl. values of the ratio for ground wood are about 1.55, while for kraft and unbleached sulfite (beaten) the value is about 3.0. It remains to be seen whether this quality varies in any one type of pulp to an extent sufficient to make the test of value for control work. A. Papineau-Couture

The folding resistance of paper. Raymond Fournier. *Papeterie* 53, 146–50 (1931).—A brief description is given of a new type of folding-resistance tester, based on the same principle as the Schopper-Riegler but quite different in construction. The test strip is 15 × 180 mm. (same as for the Schopper tensile test) and both ends are clamped in a 2-kg. wt., so that the tension is exactly 1 kg. The fold is effected by passing the test strip through a slot in a blade which is reciprocated vertically between 2

pairs of 14-mm. steel rolls mounted on ball bearings. When the strip breaks, the fall of the weight stops the motor and applies a powerful brake to the flywheel. An automatic revolutions-counter indicates the no. of double folds. A. PAPINEAU-COUTURE

Low-pressure steam and paper-machine drying. DONALD ROSS-ROSS. *Paper Trade J.* **92**, No. 8, 106–9(1931).—The superiority of the "blow-through" type of drainage system over that employing individual traps is explained and its advantages are enumerated. A "blow-through" system of paper-machine drainage, with temp. control, as installed on No. 1 machine at the Beauharnois Division of Howard Smith Paper Mills, is described in detail. It is claimed that this drying system has reduced cockling troubles, maintained more satisfactory final moisture in the sheet, and substantially increased the drying capacity. A. PAPINEAU-COUTURE

The efficient drying of paper. E. W. G. COOPER. *Paper Trade J.* **92**, No. 8, 110–2 (1931).—A practical discussion is given of the factors involved in paper drying, including notes on the selection of felts, press rolls and the use of pre-driers. A. P.-C.

White water in paper mills. A. I. MACNAUGHTON. *World's Paper Trade Rev.* **95**, 268–80, 360–8, 426, 428(1931).—General notes are given on the utilization of white water in a wide variety of mills. A. PAPINEAU-COUTURE

Utilizing fuel value of waste sulfite liquor. HERBERT S. KIMBALL. *Paper Trade J.* **92**, No. 8, 124–7(1931).—The details of Kuhles' process (*C. A.* **24**, 6008) for the concn. and drying of sulfite waste liquor are interpreted in terms of American practice, the calcns. being based on the waste liquor output of a 50-ton sulfite mill. It is estd. there can be generated 13,063 lb. of steam net per hr., at a cost of $2.65, or about $0.20 per 1000 lb. A. PAPINEAU-COUTURE

Waste liquors and gases of the paper industry. C. J. WEST. *Paper Trade J.* **92**, No. 3, 48–56, No. 4, 50–6, No. 5, 46–51(1931); cf. Schrohe and W., *C. A.* **20**, 987.—Abstracts are given of 350 U. S., Can., Brit., German, Fr., Swedish, Norwegian, Austrian and Swiss pats. issued during the period 1925–1930, compiled from *Paper Trade J.*, *C. A.* and *Papier-Fabrikant*. Author and subject indexes are appended. A. P.-C.

Color. R. CARTER. *World's Paper Trade Rev.* **95**, 716–26(1931).—After a brief review of the properties, uses and advantages of basic, acid and substantive dyes and of pigment colors, the chief tests which should be applied to dyes in the paper mill are briefly discussed. A. PAPINEAU-COUTURE

The preparation and purification of some paper makers' pigments. E. T. ELLIS. *Paper Maker & Brit. Paper J.* **Annual No.**, 32–4(1930).—A description is given of the prepn. and purification of bone black, ferric oxide, iron buff, lead chromate, manganese bronze, Prussian blue, red lead, smalt and ultramarine. A. PAPINEAU-COUTURE

The dyeing and coloring of paper. F. HAMILTON. *World's Paper Trade Rev.* **95**, 689–94, 730–4(1931).—An address is given which deals chiefly with the properties of the various classes of coloring matters. A. PAPINEAU-COUTURE

Improved constant humidity room. JAMES D'A. CLARK. *Paper Ind.* **12**, 1859–63 (1931).—A detailed description is given of a const. humidity room, based on, but somewhat modified from, that described by Ruff (*C. A.* **21**, 4067), built and equipped at a cost of approx. $1000. It has been operating with complete satisfaction since the end of 1928. A. PAPINEAU-COUTURE

The resins of jack pine. JOHN B. PHILLIPS. *Pulp Paper Mag. Can.* **31**, 211–9 (1931).—The resins were found to consist chiefly of resin acids and fatty and unsaponifiable matter. The fatty constituents, to which are generally attributed so-called "pitch troubles" in pulp and paper mills, are made up largely of acids and glycerides of the unsatd. type (including large proportions of oleic and linolic acids and traces of linolenic acid). The fats of seasoned wood were found to contain a high percentage of oxidized fatty acids, probably derived from the unsatd. acids, which oxidize and polymerize very readily. These transformations involve a change from oily, sticky material to more inert, solid products. As it is generally agreed that pitch trouble is brought about mainly by flocculation and coagulation of resin particles, it is suggested that the possibilities of triethanolamine as an agent for removing the troublesome resinous particles, or rendering them harmless, should be investigated. A. PAPINEAU-COUTURE

Two years' progress in corrosion resistance [in sulfite industry] (MATHEWS) **9**. Cr-plating of paper-mill rolls (CLEVELAND) **4**. Lignin, humic acid and humin (FUCHS) **10**. Lignin and related compounds (HIBBERT, SANKEY) **10**. Destructive hydrogenation (Brit. pat. 338,192) **21**. Solvents for cellulose esters and ethers (Ger. pat. 517,097) **13**. Obtaining cellulose from seeds (U. S. pat. 1,794,105) **27**. Synthetic rubber [for use in manufacture of threads, films, etc.] (Brit. pat. 338,152) **30**. Sugars from cellu-

losic material (U. S. pat. 1,793,084) 28. Cutting elements for paper-making engines (U. S. pat. 1,792,546) 9.

Cellulose. Steckborn Kunstseide A.-G. Swiss 142,113, May 6, 1929. Mat cellulose of good textile properties is obtained by emulsifying viscose with an agent insol. therein and adding a substance sol. both in this agent and in viscose. Thus, viscose is emulsified with toluene and acetone is added.

High α-cellulose product from wood cellulose. Zellstoffabrik Waldhof and A. Bernstein. Brit. 337,445, July 29, 1929. A cellulose contg. 98–99% α-cellulose suitable for production of cellulose acetate, nitrate or formate, etc., is obtained from bleached or unbleached wood cellulose by treatment with a 5% or stronger soln. of caustic alkali or alk. carbonate in the presence of a bleaching agent such as chloride of lime. A 2.5–5.0% alkali soln. gives a 90–95% α-cellulose. Various details of procedure are given.

Cooking sulfite cellulose. Sergei I. Chuvikovskii and Grigory I. Liachovetzkii. U. S. 1,793,264, Feb. 17. Liquor leaving the cookers is conducted to an evaporator where it is heated by fresh steam and the vapors are returned to the cookers. Various details of app. are described.

Cellulose derivatives. Courtaulds, Ltd. Ger. 514,802, Jan. 19, 1927. Alkali cellulose is subjected to the action of a small quantity of Et_2SO_4 at 25°, the free alkali is removed and the product dried and acetylated. The ethylated cellulose contains not more than one Et group to each $C_6H_{10}O_5$ group. Examples are given.

Cellulose derivatives. Soc anon. pour l'ind chim. à Bâle. Swiss 141,556, Aug. 31, 1928. Cellulose derivs. are obtained by the action of substances of the general formula: halogen - C_2H_4 - N=$(C_2H_5)_2$ on alkali cellulose. The product has basic properties which enable it to unite readily with acid dyes. Examples mention the action of chloroethyldiethylamine on cotton and cellulose. Cf. *C. A.* **24**, 4156.

Cellulose derivatives. Soc. anon. pour l'ind. chim. à Bâle. Swiss 142,173, Sept. 8, 1928. New derivs. are prepd. by treating cellulose with phthalic acid anhydride in the presence of tertiary bases. The product is a white mass with an affinity for cotton and basic dyes. In the exampl., cellulose is treated with the anhydride and pyridine at 60°.

Cellulose derivatives. Soc. anon. pour l'ind. chim. à Bâle. Swiss 142,175, Apr. 11, 1929. New derivs. are prepd. by the action of cyanuric chloride on alkali cellulose. The products are unresponsive to vat and acid dyes, but responsive to basic dyes, and can be used as the raw material for textile fibers. In an example, unbleached cellulose in KOH is treated with the chloride. Cf. *C. A.* **25**, 1092.

Cellulose derivatives. Soc anon. pour l'ind. chim. à Bâle. Swiss 142,749, Aug. 8, 1928. A new deriv. is obtained by the action of phenylisocyanate on cellulose. The product can be used to make textile fibers and has a strong affinity for basic dyes.

Acetylcellulose. Samuel I. Vles and Louis de Hoop (to Allgemeene Kunstzijde Unie N. V.). U. S. 1,794,126, Feb. 24. An acetylizing bath formed from Ac_2O and glacial HOAc is allowed to stand for several hrs. until part of the water in the acid has combined with the Ac_2O, and cellulose is then introduced into the bath.

Cellulose acetates, acetopropionates, acetobutyrates, etc. I. G. Farbenind. A.-G. Brit. 337,366, July 25, 1929. In the production of cellulose acetates, propionates, butyrates and mixed esters, the esterification is carried out in the presence of methylene or ethylene chloride as solvent instead of free acid, and by effecting the reaction at temps. of 20–60° degradation of the cellulose is avoided and clear solns. of unusual homogeneity and viscosity are obtained, which may be spun directly or may be hydrolyzed to give acetone sols. The quantity of catalyst such as H_2SO_4 used may be reduced to about 0.5%. Various auxiliary details of procedure are described.

Precipitating cellulose acetate. K. Werner. Brit. 338,214, Aug. 15, 1929. An app. is described for pptn. of primary or secondary cellulose acetates from HOAc soln. by a pptg. liquid such as water, by bringing the materials together in streams which flow into each other through a centrifugal pump to cause intimate admixt., suitably at a temp. of about 70°. A bleaching agent such as Cl gas may be supplied to the app.

Mixed cellulose esters. C. J. Staud and C. S. Wenner (to Kodak, Ltd.). Brit. 338,201, Feb. 18, 1929. Mixed cellulose esters, other than lacto-formate, are prepd. by digesting an acyl ester of cellulose such as cellulose acetate with an aliphatic or aromatic-aliphatic mono- or di-basic carboxylic acid contg. a hydroxy group in the α-position, such as lactic, tartaric, racemic, glycolic, glyceric, mandelic and malic acids. Several examples with details of procedure are given.

Mixed cellulose esters. C. J. Staud and C. S. Wenner (to Kodak, Ltd.). Brit.

338,202, Feb. 25, 1929. Mixed esters are formed by digesting an acyl ester of cellulose
as cellulose acetate with a carboxylic acid contg. a ketonic group in the α- or γ-
tion such as pyruvic, α-ketobutyric, α-ketovaleric, α-ketocaproic and levulinic
s, the reaction being preferably effected in a vessel provided with a reflux condenser,
hich a soln. of the cellulose acyl ester and reacting acid are heated to about 100°
er atm. pressure. Several examples are given.

Cellulose esters and ethers. SPICERS, LTD. Ger. 514,945, Nov. 24, 1926. Masses formed from cellulose ethers and esters or similar carbohydrates of empirical for- a $n(C_6H_{10}O_5)$, especially the org. acid esters, by incorporating with them, hepta- or ıchloropropane alone or mixed with other solvents or softening agents. Cf. *C. A.* 1237, 2840.

Solutions of cellulose esters and ethers. MAX OW-ESCHINGEN (to Radio Patents p.). U. S. 1,794,066, Feb. 24. Materials such as nitrocellulose, cellulose acetate thyl cellulose are dissolved in wood oil together with other known solvents such as)H or MeOH (the "wood oil" used being the product resulting from the distn., at ax. temp. of 120°, of residual oils obtained in the initial distn. of wood).

Capsules of cellulose hydrate. RUDOLF BEYRICH. Ger. 514,877, April 22, 1926. capsules are immersed in a bath of lower b. p. than water, *e. g.*, acetone, alc., etc., hat a complete or partial replacement of the water in the cellulose hydrate takes e by the liquid of lower b. p., so dimmishing the shrinkage duration of the capsule.

Capsules. KALLE & Co. A.-G. (Julius Voss, inventor). Ger. 517,021, Dec. 15, 5. Addn. to 515,377 (C. *A.* 25, 1072). Capsules made from viscose with which a and (or) mosaic gold has been incorporated, are rendered opaque as described ier. 515,377.

Effecting deodorization, bleaching and sterilization of fibrous materials such as saw- t. FREDERICK W. BRODERICK. U. S. 1,792,805, Feb. 17. The material is moist- ł with a dil. Na_2CO_3 soln., heated to about 38°, and treated with Cl gas so that latter reacts with the Na_2CO_3 present and forms HOCl directly on the material, ch is washed and dried. App. is described.

Waterproof fibrous products suitable for making milk bottles, etc. ALBERT L. IPP. U. S. 1,793,839, Feb. 24. A thermoplastic waterproofing material such as affin and rosin is mixed with a suspension of wood pulp at a temp. above the m. p. ie thermoplastic material, and while hot the suspension is made into the desired such as milk bottles, dishes or toys.

Bleaching bands, films, capsules, etc., made of regenerated cellulose or cellulose vatives. CHEM. FAB. VON HEYDEN A.-G. Ger. 517,284, Dec. 20, 1927. The erials are treated at atm. or raised temp. with solns. of salts of aromatic sulfochlor- des, *e. g.*, with a 2% soln. of the Na salt of *p*-toluenesulfochloramide.

Plastifiable material comprising acetylated wood. I. G. FARBENIND. A.-G. Brit. 791, Aug. 7, 1929. Material such as degummed beechwood meal is treated with vith or without addn. of concd. HOAc, in the presence of 8–14% of H_2SO_4 or an quantity of other acid such as HCl or H_3PO_4, at a temp. below 30°, and the mass which is no longer fibrous is further worked up as in cellulose acetate A product may be obtained sol. in HOAc or $CHCl_3$. Various details of pro- are given.

tificial silk. CARL HAMEL SPINN- & ZWIRNEREIMASCHINEN A.-G. Swiss 3, Nov. 13, 1929. App. is described for stretching the fibers after treating them softening bath.

tificial silk. N.-V. J. A. CARP'S GARENFABRIEKEN. Brit. 337,418, May 24, Various kinds of artificial silk such as that made from viscose, cellulose acetate ammonium cellulose are given a dull luster by treatment with a soln. of a fluosili- ither during or after manuf., under such conditions that silicic acid is pro- by hydrolysis and partly incorporated in the material so that it is not removable er, dil. acids or soap solns. Various details of procedure are described.

tificial silk from viscose. N.-V. NEDERLANDSCHE KUNSTZIJDEFABRIEK (to . Enka Artificial Silk Co., Ltd.). Brit. 337,350, June 8, 1929. Viscose is used spinning bath contg. at least 30% of sulfonic acids of aromatic hydrocarbons ly one contg. benzenesulfonic acid 37.9 and H_2SO_4 22.3%). Glucose and alcs. e added, and the filaments may be subsequently treated with water or dil. acid soln., and weakly matured viscose may be used. The product has an elonga-

[illegible]%.

silk and films from viscose. I. J. FRENKEL. Brit. 338,318, Oct. 21, In order to avoid evolution of disagreeable gases during the manuf., nitrocellulose ved in the viscose during its treatment with alkali (the nitrocellulose being de-

compd. into cellulose and $NaNO_3$ being formed, which reacts with the H_2S and other noxious gases liberated in the coagulation bath). A small quantity of hydrazine is also formed and preferably converted into a harmless complex Fe compd. by adding an Fe salt such as $FeSO_4$. The filaments made from material thus treated are chocolate-colored when first formed but assume a normal color after desulfurization. Various details of procedure are described.

Artificial fibers from viscose. ZELLSTOFFFABRIK WALDHOF and ARNOLD BERNSTEIN. Ger. 514,762, July 14, 1928. An app. is described in which the coagulating and fixing liquids are sepd. by a partition, the spun fiber passing through the top layers of these liquids.

Device for applying friction to filaments, etc., spun from viscose. HERMINGHAUS & Co. G. M. B. H. (Hugo Elling, inventor). Ger. 517,324, Mar. 18, 1926.

Use of viscose precipitating baths containing magnesium sulfate. JOHANN J STÖCKLY and RICHARD BARTUNEK (to the firm Vereinigte Glanzstoff-Fabrieken A.-G.). U. S. 1,793,649, Feb. 24. For maintaining the compn. of viscose-pptg. baths contg $MgSO_4$ and Na_2SO_4 in soln., the soln., at a $MgSO_4$ content of over 220 g. per l., is cooled to effect crystn. of $MgSO_4$ in practically pure form, the cryst. material is sepd., the resulting liquor is diluted and practically pure Na_2SO_4 is sepd. by further lowering of the temp., and the resulting mother liquor is concd. and is added with a suitable proportion of $MgSO_4$ to the pptg. bath to be revivified.

Artificial silk. A. BOSSE. Brit. 337,360, June 25, 1929. See Fr. 677,479 (*C. A.* 24, 3113).

Artificial silk filaments from cuprammonium cellulose solutions. BRITISH BEMBERG, LTD. Brit. 337,608, Nov. 19, 1928. In a method involving stretching and coagulation by a stream of precipitant flowing with a gradually increasing speed through a funnel within a spinning vessel, the fresh precipitant, before encountering the threads, is mixed with part of the used precipitant passing from the funnel through apertures into a surrounding space. App. is described.

Liquid treatments of wet cakes of artificial silk. J. P. BEMBERG, A.-G. (to British Bemberg, Ltd.). Brit. 337,590, Nov. 9, 1928. For treatments such as washing or satg. with soaps or fatty emulsions, etc., wet cakes of artificial silk contg. acid are removed from spinning pots and placed upon supports having a yielding periphery and are then immersed in the treating baths. Various details of app. and operation are described.

Apparatus for making silk filaments by the centrifugal box method. I. G. FARBENIND. A.-G. Brit. 337,610, Nov. 8, 1928. Impurities such as salts and acid are removed in a counter-current of washing liquor which preferably enters the guide funnel at its lower part and leaves at its upper part. Water or dil. H_2SO_4 soln. may be used for the washing. Various details of app. and operation are described.

Protecting rayon fibers. ARTHUR REILLY (to Twitchell Process Co.). U. S. 1,794,342, Feb. 24. Rayon fibers, after their formation and before completion of articles formed of them, are protected by coating them with inert mineral oil and "true mahogany" (a described sulfonate material).

Hollow artificial fibers. ERSTE BÖHMISCHE KUNSTSEIDEFABRIK A.-G. Ger. 517,355, Sept. 5, 1926. Hollow artificial fibers are prepd. by incorporating into the usual spinning solns. liquid or solid substances which are insol. in the solns. and which do not give rise to gases or vapors during the spinning process, the added substances being ultimately removed from the spun fibers by means of a solvent. Thus, paraffin oil may be emulsified in viscose, and after spinning, washing and bleaching, the oil particles may be removed from the fibers by means of C_6H_6.

Device for the wet spinning of artificial fibers. NOVASETA A.-G. ARBON. Swiss 142,046 and 142,047, Oct. 10, 1929. Addns. to 140,048 (*C. A.* 25, 815). Details of the funnel-shaped app. are given.

Apparatus for making artificial silk filaments. COURTAULDS, LTD. Ger. 517,325, July 7, 1927. See Brit. 275,042 (*C. A.* 22, 2273).

Spinning device for artificial silk. WEBER & Co. Swiss 142,115, Sept. 19, 1929.

Spinning device for artificial silk. CARL HAMEL A.-G. Ger. 514,667, Aug. 9, 1929.

Spinning chamber for artificial silk. EMIL BLASCHKE. Ger. 514,844, Oct. 6, 1929.

Saccharification of wood. EDUARD FÄRBER, GREGOIRE MINKOFF and THOMAS W. M. POND (to International Sugar and Alcohol Co., Ltd.). U. S. 1,795,166, March 3. Wood is first treated with concd. HCl and HCl gas in quantities insufficient to effect complete conversion into sugar, then is transferred to a diffusion battery and allowed to stand without agitation; the conversion is completed by treatment with HCl of a

lower concn. than that first used, but over 35%, and the sugar soln. is simultaneously withdrawn.

Disintegrating wood. WALDEMAR O. MITSCHERLING (to Albert M. Johnson). U. S. 1,793,711, Feb. 24. In disintegrating wood to form a product which is suitable for paper or rayon manuf., the wood is subjected to a partial vacuum to remove volatile constituents and then subjected to a relatively high gas pressure until the cells of the wood are permeated with the compressed gas, and the pressure is then suddenly released.

Apparatus (with reciprocating and rotating saws) for reducing wood to pulp. JOHN A WIENER (to Oswego Board Corp.). U. S. 1,795,064, March 3. Structural features.

Wood pulp. CLIFFORD E. PETERSON (to Champion Fibre Co.). U. S. 1,792,703, Feb. 17. Wood chips are digested in relatively dil. alk. cooking liquor such as NaOH and Na sulfide soln. with continuous withdrawal of liquor from the bottom of a body of liquor and chips and continuous addn. of the withdrawn liquor to the top of the same body; the temp. of the materials is raised to the desired cooking temp. by introducing steam directly into the lower portion of the body of materials, and the cooking temp. is thereafter maintained by indirect heating of the circulated liquid. App. is described.

Wood-pulp product suitable for paper making. GEORGE A. RICHTER (to Brown Co.). U. S. 1,793,194, Feb. 17. An unbeaten chemical wood pulp is homogeneously blended with like beaten or hydrated pulp. Cf. *C. A.* **24**, 2884.

Paper pulp from groundwood. RAYMOND S. HATCH, ROBERT B WOLF and RAYMOND P. HILL. U. S. 1,794,174, Feb. 24. Wood is ground to produce short-fibered groundwood pulp, slivers are sepd. from the pulp, the slivers are subjected to a softening and defibering treatment with a suitable soln. and the resulting pulp is mixed with the short-fibered ground pulp.

Furnace for recovery of values from waste wood-pulp liquor residuum. FERNANDO FALLA (to Edge Moor Iron Co.). U. S. 1,794,006, Feb. 24. A steam boiler is operated by the furnace gases, and cooling gases are supplied to the boiler space at a point beyond the inlet of the furnace gases so that the furnace gases will be cooled to an extent sufficient to ppt. entrained "chemical ash" from them. Various details of construction are described.

"Kraft-simulating" pulp. GEORGE A. RICHTER (to Brown Co.). U. S. 1,792,510, Feb. 17. Wood chips are digested by heating under pressure in an acid sulfite liquor in which the free SO_2 and combined SO_2 are in approx. equal proportion (of 3 to 4% each), the pulp is sepd. from the digesting liquor and is further digested in an alk. cooking liquor.

Apparatus for continuous filtration and dehydration of pulp for artificial leather or paper manufacture. C. CARCANO. Brit. 337,346, July 22, 1929. Structural features.

Hydrating and beating paper pulp. G. H. CARNAHAN (to Intercontinental Rubber Co.). Brit. 338,389, Dec. 4, 1928. Pulp is hydrated by repeated squeezing and rubbing between resilient surfaces such as rubber in the presence of water (suitably by the use of rubber-covered balls in a tube mill).

Apparatus for beating paper pulp. WM. V. KNOLL (to Mid-West Machine Co.). U. S. 1,793,095, Feb. 17. Structural features.

Paper. OTTO ENGEL. Ger. 514,787, Oct. 15, 1926. Addn. to 483,735. The method of 483,735 (*C. A.* **24**, 699), for producing layers of paper felt, cardboard, etc., with intermediate layers of fabric, gauze, bands or fibers, etc., is modified by using as the binding material, asphalt, resin, bitumen, etc., mixed with oil, tar, etc., with a m. p. considerably higher than that of the finishing material to be subsequently used.

Paper. I. G. FARBENIND. A.-G. Ger. 514,856, Aug. 14, 1926. Addn. to 500,567 (*C. A.* **24**, 4932). Cellulose material such as straw, wood, etc., is impregnated with dil. HNO_3 and treated with air after the removal of the excess of acid. The fibers are then worked up as usual.

Paper. ERNST FUES. Ger. 514,921, July 8, 1927. Paper consisting of one or more layers is impregnated, colored, glazed, etc., by sprinkling the impregnating, etc., materials on or between the paper layers in powd. form in the presence or absence of diluents, treating with solid or liquid assisting agents, and pressing over rollers. Synthetic resins of the CH_2O-PhOH types are mentioned as suitable assisting agents.

Paper-making apparatus. W. P. FEENEY. Brit. 337,532, Aug. 5, 1929. Structural features.

Paper-making machine (Fourdrinier type). PAUL ERKENS. Ger. 517,229, Feb. 25, 1927. Addn. to 406,942. Structural features are described.

Metallic cloth for paper-making apparatus. RICHARD KASTNER. U. S. 1,794,624, March 3.

Filtering apparatus suitable for treating "white water" from paper manufacture. EDWIN M. BASSLER (to D. J. Murray Mfg. Co.). U. S. 1,793,449, Feb. 17. Structural features.

Automatic apparatus for regulating the drying of paper, fabrics, etc. MASCHINENFABRIK AUGSBURG-NÜRNBERG A.-G. (Friedrich Englert, inventor). Ger. 517,332, Nov. 7, 1925.

Moistening device for paper, etc., sheets. HUBERT AUER, JOSEF DERCKS and GUSTAV RONSIEK. Ger. 517,035, April 9, 1929.

Sizing paper. KARL SVEEN. Ger. 517,228, July 21, 1925. A thin dispersion or soln. of a sizing material, *e. g.*, animal glue, in an amt. not exceeding 1 part of dry sizing material to 100 parts of dry paper is continuously added, at a point between the hollander and the wire cloth, to paper stuff contg. fillers, etc., and $Al_2(SO_4)_3$ or other usual precipitant. The sizing soln. may be stored for some time at atm. or reduced temp. before use.

Apparatus for locally applying coloring, etc., liquids to wet sheet material (paper). GEBR. PALM, PAPIERFABRIK. Ger. 517,325, Dec. 21, 1924. Addn. to 509,382 (*C. A.* 25, 817).

Waterproof flexible paper. THE SCUTAN CO. Ger. 514,922, Nov. 25, 1927. See Brit. 281,316 (*C. A.* 22, 3530).

Treating paper to improve its light-reflecting properties. NATIONAL PAPER PROCESS CO. Brit. 338,168, Aug. 14, 1929. To cause paper or other surfaces to reflect whiter light than usual, a light filter is applied to them in uniformly distributed areas which with the untinted areas reflects a combination of colors giving a substantially white effect (the individual tinted and untinted areas being sufficiently small to prevent conscious resolution at the normal viewing distance). The color applied (usually blue) is such as to counteract the preponderant colors normally reflected by the surface. Various details of manuf. are given.

Etching designs on paper. I. G FARBENIND A.-G (Kuno Franz and Karl Dankert, inventors). Ger. 514,626, June 15, 1928. Sharp etched designs are produced by treating the outer layer of paper material with the etching dye prior to subjecting the paper to the etching process.

Variegated paper. LUDWIG HENNEBERGER. Ger. 517,137, April 7, 1929. In the manuf. of variegated paper by dropping oil colors onto soft water and then contacting the paper sheet with the surface of the water, the spreading of the color is assisted by adding a little NH_4OH to the color, in addn. to the usual ox gall or alc. soap.

Anti-moth paper. CARTON- & PAPIERFABRIK G. LAAGER. Swiss 142,572, Nov. 15, 1929. An anti-moth prepn. such as tar soap is added to the pulp mass during the manuf. of the paper.

Coating paper on both sides with metal foil. LEOPOLD RADÓ. Ger. 514,577, April 1, 1927. Cf. *C. A.* 24, 4634.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE AND C. G. STORM

The characteristics of an explosive: properties determined by combustion in a closed chamber. M. E. BURLOT. *Army Ordnance* 11, 283–6(1931).—The paper describes 2 pressure-gage eprouvettes, with vols. of 25 and 150 cc., for testing pulverulent explosives and *smokeless powders*, resp., and a special calorimeter of the Landrin-Mallez type, in which the eprouvettes are immersed for detg. heat of combustion. P/Q is measured by registering the compression of Cu cylinders as a function of the time, by means of a pen attached to the crusher-gage piston, and a revolving cylinder. For measuring gas vol. (V_0) a gasometer is connected with the eprouvette through a special needle valve. T is calcd. from measured values for P and V_0, or from the equation of combustion and the value of Q detd. by the calorimeter. Potentials of explosives are measured by this app. to an accuracy of 1/1000. C. G. STORM

Consumption of explosives in January, 1931. W. W. ADAMS AND L. S. GERRY Bur. Mines, *Rept. of Investigations* 3093, 13 pp.(1931). ALDEN H. EMERY

A nitro explosive five hundred years ago. F. M. FEILDHAUS. *Nitrocellulose* 2, 12–3 (1931). E. M. SYMMES

Determination of moisture in smokeless powder by the Beneseh method. W. GRADLICH. *Nitrocellulose* 2, 13–4(1931).—Dry air is passed through smokeless powder,

the H_2O is absorbed, and EtOH and acetone vapors are oxidized by hot CuO, the CO_2 and H_2O therefrom being absorbed separately. E. M. SYMMES

A combustion theory for colloidal powders in closed vessel. HENRI MURAOUR. *Compt. rend.* **192**, 227–9(1931).—From observations on the behavior of explosive powders in a closed vessel, a theory is derived to explain the behavior based on temp., pressure and gaseous-layer effects. M. McMAHON

High-brisance studies. IV. Penthrinit versus dynamite. ALFRED STETTBACHER. *Z. ges. Schiess-Sprengstoffw.* **26**, 38–40(1931); cf. *C. A.* **25**, criticisms of Naoum (*C. A.* [illegible] compared with various types of com. *blasting gelatins*, the explosives varying in age from 30 hrs. to 34 days. The tests were made with 250 g. charges on 25 mm. steel plates, 150 g. charges on 7 mm. Fe plates resting on an Fe support, 100 g. charges on 8 mm. and 10 mm. Fe plates, and 30 g. charges stemmed in bore holes 22.5 mm. diam. × 9.4 cm. deep in steel cylinders 12 cm. diam. × 15.2 cm. high. In every case the greater brisance of the Penthrinit mixts. was demonstrated. C. G. STORM

Penthrinit, dynamite and the so-called high-brisance studies of Dr. Stettbacher. P. NAOUM. *Z. ges. Schiess-Sprengstoffw.* **26**, 40–5(1931); cf. *C. A.* **25**, 818.—N. comments on the claims of Stettbacher (cf above abstr. and *C. A.* **25**, 1674, 1998) relative to the superiority of "Penthrinit" mixts and their practical application. The plate tests of S. are interpreted as indicating relative sensitiveness to detonation rather than brisance. The more insensitive gelatin explosives require stronger confinement than that afforded in the tests of S. to develop their max brisance. Even 30 mm. steel tubes do not represent the confinement of a charge in a bore-hole in rock. The article is mainly controversial in nature. C. G. STORM

Combustion and detonation in gaseous mixtures. Antidetonants. PAUL LAFFITTE. *Bull. soc. encour. ind. nat.* **130**, 15–30(1931); cf. *C. A.* **22**, 1475, 2655; **23**, 2571; **24**, 966, 1207. ARTHUR FLEISCHER

The testing of mine dusts. A. L. GODBERT AND R. V. WHEELER. *Trans. Inst. Mining Eng.* **80**, 312–27; *Colliery Guardian* **142**, 301–4(1931).—A study of some 200 mine dusts indicates that percent of ash or incombustible dust is not a true guide to inflammability. Some 16 samples contg. more than 50% of incombustible matter were still classified as inflammable according to the test used. These tests emphasize the wide differences in inflammability that exist between coal dusts of different chem. compn. and indicate that in the use of incombustible dust as a precaution agent against coal dust, there should be greater discrimination. R. S. DEAN

The inflammation of coal dusts: effect of the presence of fire damp. T. N. MASON AND R. V. WHEELER. Safety in Mines Research Board, London, *Paper* No. **64**, 32 pp. (1931). An account is given of inter-related studies of the relative inflammability of a number of different coal dusts and the effect of the presence of fire damp in the air on the inflammability of coal dusts. There is a fairly regular relationship between the content of volatile matter in coal and the inflammability of its dust. Flame is not propagated in coal dust contg. less than 12.5% of volatile matter. The presence of fire damp in the air requires the use of a higher % of stone dust mixed with the coal dust for extinguishing the explosion of the latter. When 2.5% of fire damp was present, coal dust contg. only 7.5% volatile matter was just capable of propagating flame under the conditions of the expts. The tests were conducted in a steel gallery 48 in. in diam. and 325 ft. long, in which ignition was effected by a blown-out shot of 20 oz. of black powder stemmed with 1 lb. of coal dust from a steel cannon with 2-in. bore. C. G. S.

Gaseous explosive reaction: effect of pressure on the rate of propagation of the reaction zone and on the rate of molecular transformation. F. W. STEVENS. *Natl. Advisory Comm. Aeronautics, Rept.* No. **372**, 3–19(1930); cf. *C. A.* **24**, 1982.—A beam of light interrupted by a tuned shutter passed through a lens focused on a spark gap in the center of a soap bubble of explosive gases suspended in the center of a large sphere. Through a second window, opposite the source of light, a camera focused on the spark gap recorded the explosive transformation on a moving film. The reactions (I) $2CO + O_2 \longrightarrow 2CO_2$, (II) $CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$, (III) $2C_4H_{10} + 13O_2 \longrightarrow 8CO_2 + 10H_2O$, (IV) 1.8 Fuel + $1.2O_2 \longrightarrow 1.8CO_2 + 0.4H_2O$, (V) 1.5 Fuel + $1.5O_2 \longrightarrow 1.5CO_2 + H_2O$ were studied over a range of pressures from 100 to 2650 mm. In all reactions studied, irrespective of the order given by stoichiometric equations from 3 to 15, the rate of transformation is proportional to the pressure. This indicates a much simpler reaction than is indicated by stoichiometric equations in accord with the impact theory. The findings are strong evidence in support of the theory of chain reactions. High order reactions proceed by many simultaneous simple reactions. Previous investigators, working in const. vol., have in most cases given the

rate of displacement of the reaction zone and not the rate of propagation of the zone relative to the gas it transforms. Conclusion: "The rate of propagation of the reaction zone within the gases is independent of the pressure," from which it follows that the "rate of mol. transformation within the reaction zone is proportional to pressure." In const.-vol. measurements of rate of propagation the generally noted fact that the rate of propagation is uniform for a time after ignition is due to the approach to const. pressure conditions during this time. The work of others is discussed. A bibliography is given. A. LLOYD TAYLOR

Sensitivity of nitroglycerin: effect of static electricity on it and related compounds. H. E. NASH. *Army Ordnance* 11, 384–5(1931).—Sparks were passed through pieces of filter paper satd. with the liquid explosives, or through small samples on a Cu plate. The condenser furnishing the spark was of 0.008 mfd. capacity. Voltage varied from 5000 to 13,000. No explosions or ignitions were obtained in repeated tests with nitroglycerin, mixts. of nitroglycerin and *ethylene glycol dinitrate, propylene glycol dinitrate, nitrosucrose,* and 40% *dynamite.* With a 50% soln. of *DNT* in anhyd. EtOH, ignition of the EtOH vapors occurred. In all tests the samples were surrounded by a cylindrical water jacket to maintain the temp. at the desired point, usually 50–60°. The insensitivity of the liquid explosives to sparks is attributed to their low vapor pressure. Conclusion: Static electricity is not a hazard on nitroglycerin lines in dynamite plants. C. G. STORM

Fire, explosion and health hazards with zapon (nitrocellulose) lacquers. MAX GREMPE. *Nitrocellulose* 2, 36–8(1931). E. M. SYMMES

Two little-known sources of explosion. HANS WOLF. *Chem.-Ztg.* 54, 796(1930). Iron sulfides resulting from the corrosion of gasometers by S products in illuminating gas can ignite spontaneously. Thin Al foil or Al bronze dust is capable of igniting under the influence of a strong light. A. L. HENNE

Gas-analysis apparatus [for attachment to a miner's lamp] (Brit. pat. 338,410) 1

Poudres et explosifs. Volume mis à jour à la date du 1 Janvier, 1930. Paris: Charles Lavauzelle et Cie. 199 pp.

Explosive primer composition. CHARLES H. PRITHAM. U. S. 1,794,732, March 3. Hg fulminate 37, $Ba(NO_3)_2$ 32, Sb sulfide 28, ground glass 3 and a high explosive such as trinitrotoluene 4–8 parts are used together.

Propellent explosive comprising colloidized nitrocellulose. CHARLES M. A. STINE and CHARLES E. BURKE (to E. I. du Pont de Nemours & Co.). U. S. 1,792,516, Feb. 17. Nitrocellulose is colloidized with a nitrated ester of lactic acid and a polyhydric alc. such as dinitroglycerylnitrolactate and nitroglycerylnitrolactate or glyceryldinitrolactate.

Paper shot shells. WATSON H. WOODFORD (to Remington Arms Co.). U. S. 1,795,191, March 3. A portion of the paper shell wall is impregnated with a heat absorbent comprising a lacquer plasticizer, such as various described varnish or lacquer compns. Cf. *C. A.* 24, 4398.

Nitrated ester of lactic acid and glycerol, etc. CHARLES M. A. STINE and CHARLES E. BURKE (to E. I. du Pont de Nemours & Co.). U. S. 1,792,515, Feb. 17. A nitrated ester of lactic acid and glycerol is prepd. by nitrating a glyceryllactate with HNO_3 and H_2SO_4 and may be used in explosives with nitrocellulose, etc. Nitrolactates of ethylene glycol are also mentioned.

Electric blasting fuses. LIGNOZA SPOLKA AKCYJNA. Brit. 337,837, June 15, 1928. Structural features.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

The constitution and properties of level-dyeing rayon dyes. KARIN SCHULZE. *Seide* 36, 43–7, 85–90(1931). H. W. STIEGER

Azo dyes and their intermediate products. V. Constitution and degree of dispersion of azo dyes. PAUL RUGGLI AND ARTHUR ZIMMERMANN. *Helv. Chim. Acta* 14, 101–26(1931); cf. *C. A.* 25, 417.—Substantive dyes for cotton are usually colloidal in soln. In this work an attempt has been made to trace a relationship between the constitution of such dyes, their affinity for cotton, and their degree of dispersion as measured by the viscosity of a dil. soln. and the rate of diffusion through a 1% gelatin

soln. Definite conclusions are difficult to form. Much depends on the number and position of the SO_3H groups. A large amt. of tabulated data is given which cannot well be abstracted. VI. Relation between molecular size and properties of azo dyes. *Ibid* 127–41.—A series of dyes were prepd. by a successive 2,6′ diazo coupling of 2, 3, 4, 5 and *x* mols. of J acid (2-amino-5-naphthol-7-sulfonic acid). All showed more or less affinity for cotton, but from a technical standpoint would be considered very poor substantive dyes. J acid alone does not dye cotton. The 2-J compd. in soln. is highly dispersed. The *x*-J compd. is coarsely dispersed, nearly insol., does not diffuse, and dyes poorly. The others diffuse about the same rate as Congo red and their degree of dispersion approaches that of other substantive dyes, but even the 5-J compd., with a higher mol. wt. (1349) than any known azo dye, can hardly be classed as a true substantive, nor a true colloid, but is on the border line. L. E. GILSON

The resistance of coloring substances to ultra-violet light. II. GIUSEPPE A. BRAVO. *Boll. ufficiale stas. sper. ind. pelli mat. concianti* 8, 184–90(1930).—A continuation of earlier work (*C. A.* 24, 2888). Measurements are given of dyes belonging to the nitro, nitroso, azo, stilbene, pyrazolone, diphenylmethane and triphenylmethane series. G. SCHWOCH

Relation between fading of dyed colors in light and their color-depth. H. SOMMER. *Z. angew. Chem.* 44, 61–5(1931).—It is well known that pale shades of dyed colors fade more strongly in light than the heavier shades. By employing a Zeiss graduated photometer for the measurement of color by the Ostwald system it is possible to establish a relation between the depth of color and the amt. of fading. The general process to be carried out for the detn. of this relation is described. Graphs are given plotted on the triangulated coördinate system, and expressed in the Ostwald color units, with a dyeing of Anthracene Blue SSWG extra on wool. The relations deduced are expressed in math. formulas, such as $A = n\sqrt{t}$, where A = the Ziersch degree of bleaching, t = the time of the action expressed in normal bleaching hrs., and n = the "bleaching-coefficient," being a const dependent on the light-fastness of the dyestuff. Also the relation between the collective range of different depths of dyed color and a definitely established normal is given as: $A = N\sqrt{t}\,(\log c - \log f)$, where N is the "bleaching constant" detd. empirically from a comparison of different depths of dyed color, where c = the dyestuff quantity used and f = dyestuff quantity absorbed. The deduction of such a complicated formula from one set of expts. on Anthracene Blue is assuming rather too much, but this is simple compared with further formulas involving exponential equations expressing the psycho-phys. laws of Fechner with respect to color phenomena. J. M. MATTHEWS

Chlorinating and dyeing woolen goods. J. ROBERT. *Bol. laniera* 44, 834–5 (1930).—Treat woolen yarn for ¼ hr. with 100 l. H_2O, contg. 1.5 l. HCl (22° Bé.), eliminate excess of bath, treat in 10–20% $Ca(OCl)_2$ for ½ hr., and again in the 1st bath for 20 min. and in a cold bath with 5 g. $NaHSO_3$ per l. H_2O. After washing, initiate dyeing at a lower temp. than usual, and without acid in the case of easily absorbed colors, only adding it gradually until exhausting the bath. For a scroop treat in the cold with 5 g. soap per l., dry slightly and acidify with dil. HCl, H_2SO_4 or tartaric acid. For a soft grip treat 10–15 min. in a cold bath with 8–10 g. soap, 1–2 g. olive oil, and 3–4 g. ammonia (24° Bé.) per l. H_2O. Woolen muslins absorb 120–160 g. active Cl, while heavier articles take ¼ to ½ this quantity. Chlorination is often followed by a passage in Na stannate of 3–6° Bé., leaving the wool to itself for some time, and fixing with H_2SO_4 of 10° Bé., washing and drying. To prevent the yellowing of whites during the steaming for fixing printing colors, the cloth is prepd. with 15–20 g. Na stannate per l., and dried without souring. The same effect is obtained by passing in a bath with 50 g. oxalic acid per l. R. SANSONE

The dyeing of wool with vat colors. L. RINOLDI. *Bol. laniera* 43, 989–92(1929).—Indigo dyeings on wool sometimes have reduced fastness to light, attributed to hyposulfite, free S, colloidal S, H_2SO_4, or sulfites formed by decompn., to strong alky. or acidity, to the color absorption conditions, or to the addn. of glue. When reduced color is absorbed, even if combined with alkali, it remains in a colloidal soln., and acts as a direct product, being absorbed mechanically as aggregated mols. When absorbed as a sulfonate it acts as a well-dissolved acid color, and is fixed by the wool as simple mols., much less resistant than mol. aggregates. Weakening of the wool is caused by NaOH, and by too much hyposulfite, which provokes, even after taking from the bath, an excessive oxidation that also destroyed a part of the color. R. SANSONE

Dyeing wool with tin salt and oxalic acid. J. ROBERT. *Boll. laniera* 44, 837 (1930).—When cochineal or quercitron is used with aniline colors for dyeing wool

in shades faster to light and alkalies, prepare a bath contg. oxalic acid 2, salt 1.5, cream of tartar 1.5 and $SnCl_2$ 1%. Add the cochineal powder, after making into a paste with a little Sn salt soln., dye at the b. p. 1 hr. and wash in soft water. Cu and Fe must be absent, and wooden vats are preferred, when tinned Cu or Sn vats are not available. Orange II, palatin scarlets, ponceaux R and the rhodamines, are used in the cochineal bath after this has been fixed on the wool, although better results are obtained by using them in a fresh bath. With the phloxins and eosins this is indispensable.
R. SANSONE

Faults in the dyeing of rayon viscose and their prevention. L. RINOLDI. *Boll. laniera* **44**, 201–5(1930).—Uneven shades and other faults are produced on viscose silk during dyeing, by colloidal S, sulfides or polysulfides coming from the manufacturing process, and by ununiform threads. The S oxidizes to H_2SO_4, weakening the fiber. Deacidification with Na_2CO_3 or NaOH is not enough for uniform shades with direct or S colors, for the fiber in the more altered parts dyes less. Better results are obtained by treating with NaOH at 50–60° and addn. to the dye bath of soap, sulforicinate, pyridine, old degumming baths and glue. The greatest uniformity is obtained during the most rapid dyeing and near the b. p. Colors strongly fixed in tepid baths give more regular shades at 90–95°. With dark shades, for exhausting the bath there is added, after ½ hr. dyeing, 5–20% Na_2SO_4. Many dyers avoid this, as it can produce uneven shades.
R. SANSONE

Dyeing unmordanted cotton in cold or tepid concentrated sea-salt baths. J. ROBERT. *Boll. laniera* **44**, 837(1930).—The eosins, erythrosins, phloxins, Bengal pinks and certain acid colors are dyed in a lukewarm bath contg. 50 g. sea-salt per l. Quinoline yellow S, naphthol yellow S and metanil yellow are dyed in a lukewarm bath with 10–20 g. sea-salt per l. Azoflavine RR, orange II, orange GR, ponceaux R and fast ponceaux need instead a bath with 10–20 g. sea salt and 0.5–2 g. alum per l. The cotton is dyed for ¾ hr., freed from the excess of bath and dried in the cold without rinsing in water. Very bright shades are obtained with a mediocre fastness to washing. From 2 to 10 kg. of color is needed for every 100 kg. of cotton. The baths exhaust badly.
R. SANSONE

Conditioning textiles in laboratory experiments. W. WELTZIEN. *Seide* **35**, 482–6 (1930).—A photographically illustrated lab. app. for conditioning textile samples is explained and discussed.
H. W. STIEGLER

Physical and chemical properties of textiles. I. A. J. HALL. *Textile Mercury* **84**, 211(1931).—X-ray methods are discussed and the micelle structures of cotton and rayons are correlated with the fiber properties of dyeing, luster and resistance to decompn. by snail enzyme. The following figures give % degradation of cellulose by snail enzyme (p_H const. at 5.28 by Na phosphate buffer, temp. 36°, time 6 days): *Cotton 2.1, filter paper 7.1, cotton, solvent extracted and mercerized, 10.2, cellulose regenerated from nitrocellulose 7.8, cuprammonium cellulose 18.3, viscose cellulose 23.1, alkali sol. cellulose prepd. from nitrocellulose 32.4, cellulose regenerated from acetyl* cellulose 70.0, alkali-sol. cellulose prepd. by treatment with HCl 68.5.
A. K. J.

Some physicochemical properties of the wool fiber. J. B. SPEAKMAN. *J. Textile Sci.* **4**, 6–9(1931).—This paper relates chiefly to the adsorption of dyes by wool. Dye mols. are so enormous that there would seem to be little chance of their ever entering the fiber. The size of the pores in the dry fiber were detd. by reaction with alc. hydroxyl groups associated with stretching of the wool, the work required to stretch the fiber being measured first in water, and then in MeOH, EtOH, etc. The alcs. employed increase progressively in mol. size and wt. The resistance to extension increases until butyl alc. is reached when the fiber behaves as it does in dry air. Alcs. beyond butyl, therefore, do not enter the wool mol., and therefore the size of the pores in the dry wool fiber is approx. the same as the length of the *n*-propyl alc. mol. The work required to stretch wool fibers 30% (g. cm. per cc.) in various media at 22.2° is 5.37×10^8 for octyl alc. and 1.63×10^8 for ethylene glycol. The increase of pore size of wool fibers swollen in water is more than 100%. Dry wool fibers immersed in water give an increase in length of 1% and an increase in diam. of 18%. Water and other reagents are adsorbed on the surfaces of the constituent micelles, causing a swelling of the fiber. Actual detns. of the pore size show the micelles are about 200 A. U. thick. The size of the swollen pores is about 40 A. U. Thus any dye having a mol. greater than this size is only adsorbed on the exterior of the fiber and will be deficient in fastness to rubbing. On transferring the dry wool fiber from dry air to water the breaking load of the fiber is changed from 22.1 to 14.9×10^8 g./cm.^{2}. The increase in cross-section is about 40% and the rigidity is altered in the ratio of 15:1 as compared with the breaking load. This indicates that the micelles are much longer than they are thick. The conclusion

is that the wool fiber is built up of tiny plates, 200 A. U. thick, the long axis of the plates being parallel with the length of the fiber. When the wool is swollen in water the distance sepg. the surfaces of the plates is about 40 A. U., whereas in the dry fiber this is only 6 A. U. J. M. MATTHEWS

X-ray investigations of the inner structure of wool. W. T. ASTBURY. *J. Textile Sci.* **4**, 1-5(1931).—The minute structural elements of the wool fiber may be studied with the aid of x-rays. Wool is a complex biol. structure built up from the protein keratin which is characterised by containing S in the mol. The elements of the wool fiber are "to a large extent" cryst., meaning that the constituent mols. are built together in a regular 3-dimensional pattern Wool is generally called colloidal, but this is because its crystals are so minute. X-ray photographs are given showing that stretched wool fibers have a different crystallographic structure from the unstretched, the latter is called α-keratin and the former β keratin, though this difference is postulated entirely on the showing of the x-ray photographs and is not substantiated by any chem. analysis. Wool, when wetted, may be stretched to twice its normal length without losing its elasticity or its ability to regain its normal length when dried. But stretched wool is very susceptible to the action of steam, so that the β-keratin loses its power of returning to the α-form. The stretched wool is 20 times as sensitive to the action of Na_2S soln. as the unstretched fiber. The x-ray measurements indicate that the α to β transformation is associated with a mol elongation of from 5.15 to 10.2 A. U. along the axis of the fiber. Spatial mol. models are given showing a theoretical structure on the wool mols. J. M. MATTHEWS

The oiling of wool by means of glycerol. A. M. SEREBRIAKOV *Nili (Suppl. to Izvestiya Tekstil. Prom u Torgovli)* **1**, Nos. 4-5, 16-7(1930); *Chimie & industrie* **25**, 165(1931). - Though attempts to substitute glycerol for spinning oils have not previously been successful with high-grade wools, excellent results were obtained in the present tests by using 20-30% glycerol on wool which had been incompletely scoured and still contained a relatively large amt. of grease. Tests showed that Turkey-red oil also can be used satisfactorily, but its use will depend on the price. A. P.-C.

The oxidation of the fat used in oiled wool. G SALOMONE. *Boll. laniera* **44**, 297-300(1930) - The oils used for wool should be easily absorbed, should furnish emulsions in water with very fine fluid particles covering easily and equally the wool fibrils, should not become agglutinated in the air, should not have any corrosive action, should be very little oxidizable, should develop little heat, should be easily eliminated by a weak alkali and should give no disagreeable odor or color The oils extd. from woolen yarn stored for some time are colored brown, and have an unpleasant odor; their fatty acids turn the wool a yellow brown, not always eliminated by scouring, even with volatile solvents. Rancid oils can cause a sensible reduction in the resistance of the wool, and after scouring, a slight increase in the soly. in water, in acid and in alk. solns. The more satd. fatty acids are altered less easily. They give with soap solns. very good emulsions, but melt too high, having a weak lubricating action. Some of their esters, e. g., Me, Et or Am stearate, or Me or Et palmitate can replace natural oils and olein; they can be used alone or in mixt. with oleic acid, emulsifying easily, giving emulsions with very minute particles and an increased stability. R. SANSONE

Determining the size in cotton cloth. CAMILLO LEVI. *Boll assoc. ital. chim. tessile e color.* **6**, 249-59(1930).—To det. the amount of size, 10 g. of the cotton cloth was immersed in distd. water, boiled 15 min., treated in 500 cc. of a 1% rapidase soln. at 80-85° for 3 hrs., washed with warm distd water and cold water, boiled 15 min. in 500 cc. of 0.2% Na_2CO_3 soln., washed again with warm distd. water and cold water, with light rubbing, washed with alc. and then with ether and dried at 100-105° to a const. wt. R. SANSONE

Linseed oil size and viscose silk. K GÖTZE. *Seide* **35**, 445-9(1930).—The use of linseed oil size applied in org. solvents and as an emulsion is discussed. When used in solvents the oil penetrates the fiber but as an emulsion it penetrates only slightly. Oxidation of the oil can damage the fiber if the rayon is left on bobbins for some time. It also alters the oil, making it difficult to remove, causing streaks and affinity for acid dyes, thus preventing a pure white rayon in wool-rayon mixtures. Increase in wt proceeds with oxidation. Oxidation takes place in two steps, rapid and slow. The former causes coagulation and film formation and is desired. Catalysts or ozone complete it in 24 hrs. The slow oxidation decomposes the mol. into acids. Manganese and lead are used as oxidation catalysts. The lead, however, has a tendency to discolor later on when wool-rayon mixts. are scoured in alkali. The brown color can be obviated by adding perborate to the scouring bath. Regarding strength and elasticity, no difference was found between the soln. and emulsion methods of application. Tables

show strength variations after three months' storage. Foreign materials in the size baths can act destructively on the fiber because of decompn. of the oil. Sulfur does this especially in the emulsion method. Scrooping has no effect on strength. Iron and copper can cause damage in either method. H. W. STIEGLER

International tests for artificial silk. W. KÖNIGS. *Seide* 35, 392–4(1930).—Drying data obtained at Krefeld are presented and discussed. H. W. STIEGLER

Silk weighting and fiber swelling. H. POHL. *Seide* 36, 17–9(1931).—Many measurements of fiber cross section and fiber width are summarized in table form Charts are given for tin-phosphate-silicate and tin-phosphate-logwood weighting In general, swelling is proportional to weighting. Tin-phosphate-logwood weighting causes greater swelling than tin-phosphate-silicate, the ratio being 2.13:1 for the increase in cross section. Calcn. of swelling from measurements of fiber width is not as reliable as actual cross-section measurements. H. W. STIEGLER

Temperature control in processing of silk. FRANK A. WESTBROOK. *Am. Silk J.* 50, No. 3, 56–8(1931).—The importance of temp. in various textile processes makes the installation of automatic temp.-control devices on all units desirable. Some optimal process temps. are furnished. H. H. MOSHER

The bleaching of textile fibers. F. HERNANDEZ. *Quim. e ind.* 7, 281–6(1930); cf. *C. A.* 25, 820.—Discussion of the usual methods for bleaching and subsequent treatment of linen, cotton, flax, hemp, ramie, jute, silk, etc. Bleaching with H_2O_2, Na_2O_2, sodium perborate, $KMnO_4$, H_2SO_3, SO_2 and Na_2SO_3 is also briefly discussed with practical data. S. L. B. ETHERTON

Siliceous CaO compounds [for dyeing] (Ger. pat. 514,742) **18.** Wax emuls. [for waterproofing fabrics] (Brit. pat. 338,176) **18.**

PEARSON, HERBERT P.: **Das Wasserdichtmachen von Textilien.** Translated Paul Krais with an original paper on "Die Herstellung wasserdichter Stoffe mit Hilfe Kautschuk" by F. Kirchhof. Dresden: T. Steinkopff. 74 pp.

Dyes. I. G. FARBENIND. A.-G. Brit. 337,374, April 26, 1929. 1,2,5 or 1,2 phthaloylacridone and various other compds. having a condensed ring system of at least 5 rings comprising the acridone ring system, at least 2 further carboxylic rings [illegible] connected with the condensed ring system, and at least 2 ketonic groups being contained in the compds. in addn. to that in the acridone ring, are treated with Cl or Br or [illegible] with chlorinating or brominating agents, preferably in the presence of a suitable diluent such as trichlorobenzene and a catalyst such as I or S, metals, Se or P. Numerous examples are given, for producing dyes several of which dye orange-red shades

Dyes. I. G. FARBENIND A.-G. Brit 338,182, Aug. 7, 1929. 4,*Bz*-3,4,5 to 1-haloanthraquinone-2,1-benzacridones are made by treating anthraquinone-2,1-benzacridones halogenated at least in the *Bz*-4-position and having the *Bz*-2-position free from halogen, with halogenating agents in the presence of org. solvents When using starting materials having the 4-position free, only chlorinating agents are employed as Br enters the 4 position only in small quantities. Several examples are given

Dyes. I. G. FARBENIND. A.-G. Brit. 338,216, July 5, 1929. *Bz*-2,4 Dihalo- and *Bz*-2,3,4,5-tetrahaloanthraquinone-2,1-benzacridones are prepd. by condensing 1-haloanthraquinone-2-carboxylic acids with 3,5-dihaloanilines and 2,3,4,5-tetrahaloanilines, resp., followed by ring closure. The tetrahaloanthraquinone-2,1-benzacridones also may be prepd. by treating anthraquinone-2,1-benzacridones halogenated at least in the *Bz*-2,4-positions but not completely halogenated in the benzene nucleus, with brominating agents or by treating these anthraquinone-2,1-benzacridones with chlorinating agents followed by treating the products with agents replacing halogen by H, or by treating 4-*Bz*-2,3,4,5-pentahaloanthraquinone-2,1-benzacridones with agents replacing halogen by H. Several examples are given, the products dyeing brilliant orange shades.

Dyes. I. G. FARBENIND. A.-G. Brit. 338,217, July 6, 1929. 4,*Bz*-4,5-Pentahaloanthraquinone-2,1-benzacridones are prepd. by condensing 1-haloanthraquinone-2-carboxylic acids or their esters with tetrahaloanilines having a free *o*-position to the amino group, followed by acridone ring-closure; or, the same products may be obtained by treating anthraquinone-2,1-benzacridones contg. halogen at least in the *Bz*-2- and *Bz*-4-positions with halogenating agents in the presence of an org. solvent. When starting with compds. having the 4-position free, only chlorinating agents are used, as Br only enters this latter position in small quantities. The products are dyes giving brilliant red dyeings. Several examples are given.

Azo dyes. I. G. FARBENIND. A.-G. (Winfrid Hentrich and Rudolf Knoche, inventors). Ger. 517,437, Mar. 31, 1928. The diazo compds. from amines of the formula $RSO_2C{:}C(NH_2).CH{:}CH.C(NO_2){:}CH$, where R is an aryl residue contg. at least one sulfo group and free from or contg. other substituents, are coupled with sulfonic acids of 2-aminonaphthalene or 2-amino-8-hydroxynaphthalene or their *N*-substitution products. Examples are given.

Azo dyes. I. G. FARBENIND. A.-G. (Leopold Laska and Arthur Zitscher, inventors). Ger. 517,438, May 8, 1928. Diazo, tetrazo or diazoazo compds. not contg. SO_3H or COOH groups are coupled with 2',3'-hydroxynaphthoyl-4-aminodiphenylamine or its derivs. substituted in the diphenylamine residue. Coupling may be effected in substance or on a support. The products are red, brown or black dyes insol. in water. Numerous examples are given.

Azo dyes. I. G. FARBENIND. A.-G. (Heinrich Clingestein and Karl Dobmaier, inventors). Ger. 517,439, Dec. 6, 1928. The diazo compds. from *o*-aminobenzophenone and its derivs. or substitution products not contg. a sulfo group, are coupled with suitable components such as naphthols, arylides of 2,3-hydroxynaphthoic acid, etc. Coupling may be effected in substance or on a support. The products are yellow to red dyes insol. in water. Examples are given.

Azo dyes. HERMANN WAGNER and KARL BECK (to General Aniline Works). U. S. 1,794,219, Feb. 24. Azo dyes of excellent fastness and of favorite tints are obtained by coupling, in substance or on the fiber, a diazotized 2,3-aminonaphthoic acid ester or a substitution product thereof with a naphthol or with a 2,3-hydroxynaphthoic acid arylamide or a substitution product thereof. The dyes are characterized by the formula: $3,2\text{-}(R_1OOC)C_{10}H_6N{:}NC_{10}H_5(OH)R_2\text{-}1,2,3$, wherein R_1 stands for an alkyl group, R_2 stands for H or the group CONHaryl and wherein the aryl nuclei may contain substituents, such as the NO_2 group or halogen, but contg. no free sulfo or carboxy group. Several examples are given with details of dyeing processes. Cf. *C. A.* 24, 2304.

Azo dyes. KARL HEUSNER and MAX SIMON (to General Aniline Works). U. S. 1,795,125, March 3. Dyes of the general formula $RN{:}NR_1NHSO_3H$ wherein R represents the residue of any diazo compd. and R_1 a benzene nucleus, which may be substituted are obtainable, for instance, by coupling any diazo compd. with a sulfaminic acid of the benzene series such as the sulfaminic acid of aniline, a toluidine or a cresidine. They are, when dried and pulverized, generally reddish to brownish powders dyeing wool in yellow to orange shades. An example is given of the use of acetyl *p*-phenylenediamine and the Na salt of 2-sulfamino-4-methyl-1-methoxybenzene as starting materials.

Azo dyes containing chromium. HUGO SCHWEITZER (to General Aniline Works). U. S. 1,794,252, Feb. 24. Products dyeing wool clear greenish yellow shades of good fastness and suitable for use as lake or pigment dyes are obtained by boiling the aq. soln. of a dye of the general formula: $\overline{N\ Cx.CH(N{:}NR_1).CO.N}\ R_2\ SO_2C_6H_3(OH)\text{-}CO_2H\ 2,1$, wherein R_1 stands for an aromatic nucleus, x stands for the methyl or the carboxy group, R_2 stands for a benzene nucleus, wherein R_1 and R_2 may be substituted, and wherein the salicylic acid radical is attached to the sulfone group in *o*- or *p*-position in relation to the hydroxy group of the said radical (said dyes being obtainable according to the U. S. Patent 1,685,071, *C. A.* 22, 4833) with a H_2O-sol. salt of tervalent Cr, such as Cr formate, Cr acetate or Cr fluoride, for about 2–4 hrs. Examples with details of procedure are given.

Pyrazolone azo dyes. HERMANN WAGNER, HEINZ EICHWEDE and ERICH FISCHER (to General Aniline Works). U. S. 1,794,218, Feb. 24. Dyes giving yellow tints on wool are obtainable by coupling any diazo compd. with a compd. of the general formula $2,4,5\text{-}(HO_2S)ClMeC_6H_2\overline{N\ CO.CH_2.CX{:}N}$, wherein X represents a methyl, carboxyl or a carboxylic acid ester group. These compds., which have not yet been described, are obtainable in the known manner by condensing the hydrazine with acetoacetic ester or oxalacetic ester. Several examples are given.

Producing azo dyes on acyl celluloses. FRIEDRICH FELIX and WOLFGANG JAECK (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,793,390, Feb. 17. Products such as "acetate silk" are dyed with an azo dye of the general formula, $NH_2.R'.N{:}N.R''.NH_2$ in which R' and R'' signify 2 aryl residues which may be different from each other (such as the diamino azo dye obtained by saponifying the coupling product from diazotized *p*-aminoacetanilide and cresidine) and the material is then treated with

nitrous acid and further coupling is effected with β-hydroxynaphthoic acid (or with β-naphthol for producing a somewhat less light-fast dyeing) in a medium with a p_H below 7.1. Various details of procedure are given.

Monoazo dyes. J. R. GEIGY SOC. ANON. Brit. 337,577, Oct. 15, 1928. Monoazo dyes giving clear red shades, fast to light and acid or alk. fulling, on wool and silk are made by combining a diazotized aryl or aralkyl ether of *o*-aminophenol or a substitution product with a *N*-arylsulfo-1-amino-8-naphtholdisulfonic acid. Several examples are given.

Vat dyes. HEINZ SCHEYER (to General Aniline Works). U. S. 1,793,138, Feb. 17. A 2-aroylpyrazoleanthrone contg. in the pyrazole ring the free imino group and in the aryl residue a halogen atom in *o*-position to the keto group such as dichlorobenzoylpyrazoleanthrone or like compd. in which the anthraquinone as well as the benzene nucleus may contain substituents, is treated with an inorg. substance of feebly alk. reaction such as KOAc or Na_2CO_3, suitably in the presence of a diluent such as $PhNO_2$ and a catalyst such as Cu powder, producing products which dye cotton from a violet vat fast blue shades. Details of procedure are given.

Vat dyes. I. G. FARBENIND. A.-G. Brit. 337,741, July 4, 1929. Anthraquinonylaminobenzanthrones contg. 2 or more anthraquinonylamino groups, one of which is in the *Bz*-1-position, are converted into vat dyes by treatment with alk. condensing agents, as by fusion with alc. KOH. Numerous examples are given of the production of dyes producing brown shades in most cases.

Vat dyes. I. G. FARBENIND. A.-G. (Fritz Baumann, inventor). Ger. 513,608, April 10, 1929. Vat dyes are produced by introducing a substituted or unsubstituted anthraquinone-β-carboxylic acid residue into the amino group of α-aminoanthrimidecarbazole or its derivs. and substitution products. Thus, 5,5′-diamino-1,1′-anthrimidecarbazole (obtained by sapong. 5,5′-di(benzoylamino)-1,1′-anthrimidecarbazole) is taken up in $PhNO_2$ and heated. Anthraquinone-2-carboxylic acid chloride is then added to form the dye. Other examples are given. Cf. *C. A.* 25, 1396, 1682.

Vat dyes. I. G. FARBENIND. A.-G. (Walter Mieg, inventor). Ger. 514,518, July 10, 1928. Addn. to 465,835. Vat dyes of the anthraquinone series are prepd. by the action of condensing agents (especially $ClSO_3H$ or H_2SO_4) on dianthraquinonylamines which contain at least one halogen-substituted acridone ring and at least one acylamino group, at low temps. The product may be oxidized. Thus, the dianthraquinonylamine deriv. prepd. as described in Ger. 513,045 (*C. A.* 25, 1396) by the condensation of 1 mol. of trichloroanthraquinoneacridone with 1 mol. of 1-benzoylamino-5-aminoanthraquinone, is treated with concd. H_2SO_4. The product is treated with Na_2O_2 to give a dye which colors cotton in fast black shades. Other examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Heinrich Neresheimer and Georg Bohner, inventors). Ger. 517,277, Oct. 3, 1929. Vat dyes are prepd. by halogenating α-arylaminoanthraquinonealdehydes contg. at least one CHO group in *o*-position to an NH group, and free from or contg. other substituents. Examples are given of the prepn. of dyes from 1-phenylaminoanthraquinone-2′-aldehyde, 1-phenylaminoanthraquinone-2-aldehyde and 1,5-diphenyldiaminoanthraquinone 2′,2″ dialdehyde.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz, Karl Köberle and Erich Berthold, inventors). Ger. 517,440, July 27, 1929. Addn. to 409,169 (*C. A.* 24, 4168). Vat dyes contg. more than one halogen are prepd. (1) by treating dibenzanthrone or isodibenzanthrone or their derivs. with at least two different halogens or halogenating agents, simultaneously or in succession, or (2) by introducing into halodibenzanthrones or haloisodibenzanthrones a halogen other than that already present, or (3) by treating polyhalodibenzanthrones or polyhaloisodibenzanthrones so that the halogen is partly replaced by another halogen, or (4) by treating substitution products of dibenzanthrone or isodibenzanthrone so that a nitro, sulfo or other substituent group is replaced by halogen, and then introducing a different halogen, if necessary. Examples are given. Cf. *C. A.* 25, 2003.

Vat dyes. I. G. FARBENIND. A.-G. (Robert Berliner, inventor). Ger. 517,441, Aug. 8, 1928. Carbazole derivs. useful as vat dyes are prepd. by the action of H_2SO_4 at a low temp., on dianthraquinonylamines contg. at least two acridone rings, the products being oxidized, if necessary. An example is given.

Vat dyes. I. G. FARBENIND. A.-G. (Filip Kačer, inventor). Ger. 517,443, April 12, 1929. Vat dyes giving yellow shades on cotton are prepd. by heating 3-mercapto-2-methylanthraquinone or its derivs. with S. An example is given.

Vat dyes. I. G. FARBENIND. A.-G. (Karl Schirmacher and Karl Eishold, inventors). Ger. 517,444, May 31, 1927. See Brit. 291,361 (*C. A.* 23, 1283).

Blue vat dyes. I. G. FARBENIND. A.-G. (Paul Nawiasky, Emil Krauch and Alfred Ehrhardt, inventors). Ger. 517,278, Oct. 13, 1929. Dibenzanthrone or isodibenzanthrone or their derivs. is treated with S_2Cl_2 in the presence of a metal halide having a condensing action, *e. g.*, $AlCl_3$ or $FeCl_3$. Examples are given.

Indigoid vat dyes. ERWIN HOFFA and WILHELM LUCE (to General Aniline Works). U. S. 1,793,173, Feb. 17. Vat dyes are produced by treating with P_2O_5 a mixt. of an arylthioglycolic acid (such as 1-chloronaphthalenethioglycolic acid, β-naphthylthioglycolic acid or 6-methyl-4-chlorophenyl-1-thioglycolic acid) and an *o*-diketone capable of being coupled (such as isatin, 5,7-dibromoisatin or acenaphthenequinone). In the examples given, red and brown dyes are formed. Cf. *C. A.* **24**, 3653.

Violet indigoid vat dyes. HERBERT A. LUBS and JOSEPH G. DINWIDDLE (to E. I. du Pont de Nemours & Co.). U. S. 1,792,648, Feb. 17. By the condensation of a haloisatin chloride (such as dibromoisatin chloride or monochloroisatin chloride) with hydroxyalkylthionaphthenes such as 3-hydroxy-4-chloro-6-methylthionaphthene or 3 hydroxy-5-chloro-7-methylthionaphthene, dyes are produced which are considerably superior in brightness, shade and tinctorial value to those made by condensation of hydroxythionaphthene with isatin chloride, and subsequently brominating this condensation product. By varying the particular combination of intermediates, shades of violet may be obtained varying from reddish to bluish. Several examples with details of procedure are given.

Azophthalein dyes. J. R. GEIGY A.-G. Ger. 514,973, May 25, 1928. See Fr. 675,507 (*C. A.* **24**, 3116).

Indigoid dyes. I. G. FARBENIND. A.-G. (Walter Mieg and Rudolf M. Heidenreich, inventors). Ger. 514,515, Aug. 1, 1928. See Brit. 324,119 (*C. A.* **24**, 3380).

Indigo powder. CHARLES J. STROSACKER, HAROLD KENDALL, CHESTER C. KENNEDY and EARL L. PELTON (to Dow Chemical Co.). U. S. 1,794,805, March 3. A dispersing agent including a "spreader" such as 1% each of gelatin, NaOH and Monopol oil is mixed with indigo paste and the material is dried. The product is readily miscible with water.

Dyes of the thioindigo series. I. G. FARBENIND. A.-G. Brit. 338,104, Feb. 11, 1930. The stable reduction products of 4,4'-dimethyl 6,6'-dihalothioindigos described in Brit. 334,878 (*C. A.* **25**, 1394) are made by hydrogenating the dyes in the presence of an alkali such as Na_2CO_3 and a catalyst such as a Ni catalyst capable of promoting hydrogenation. The products may be used for printing as described in Brit. 334,907 (*C. A.* **25**, 1391).

Acid wool dyes. I. G. FARBENIND. A.-G. (Carl Taube, Ludwig Zeh and Josef Hilger, inventors). Ger. 517,276, July 25, 1929. 1-Amino-4-bromoanthraquinone-2-sulfonic acid is treated with ethers derived from aminophenols and polyhydric alcs. Thus, a blue dye is prepd. by boiling the Na salt of the sulfonic acid in water with *p*-aminophenol glycol ether in the presence of a little $CuSO_4$. Other examples are given also.

Stilbene dyes. CHEM. FAB. VORM. SANDOZ. Swiss 141,766 to 141,770, Jan. 17, 1929. Addns. to 125,479 (*C. A.* **24**, 1747). Alkali fast stilbene dyes are obtained by condensing *p,p'*-dinitrostilbene-*o,o'*-disulfonic acid with sulfanilic acid-azo-*m*-toluidine, amidoazobenzenesulfonic acid, amidoazotoluenesulfonic acid, or the dye from diazotized sulfanilic acid and *m* amino-*p*-cresol. The products are treated with oxidizing agents. The first three substances yield yellowish orange dyes and the last a reddish orange dye. An orange dye is also produced by condensing the reaction product of concd. NaOH and *p*-nitrotoluenesulfonic acid with dye from diazotized sulfanilic acid and α-naphthylamine, and oxidizing the product (141,770).

Anthraquinone derivatives. I. G. FARBENIND. A.-G. (Gustav Reddelien and Werner Müller, inventors). Ger. 517,275, Aug. 5, 1929. Hydroxyalkylaminoanthraquinones are prepd. by the reaction of aminoanthraquinones with halohydrins in the presence of an acid-binding substance. Thus, 1-aminoanthraquinone is heated with HOC_2H_4Cl at 150–155° for 5 hrs. in the presence of Na_2CO_3 to form 1-β-hydroxyethylaminoanthraquinone. Other examples are given also. The products dye acetate silk, wool, etc.

Benzanthrone derivatives. I. G. FARBENIND. A.-G. (Max A. Kunz, Rudolf Stroh and Hermann Dimroth, inventors). Ger. 517,069, Mar. 12, 1929. New compds. are prepd. by treating benzanthrone or its derivs. with alkylated aromatic amines in the presence of a halide of Al. Thus, benzanthrone may be agitated with $PhNMe_2$ at 60–70° in the presence of $AlCl_3$. The products are sol. in acids, and can be vatted only with difficulty, if at all. They are useful as *intermediates for dyes*. Examples are given.

Arylaminoanthraquinones suitable for dyeing cellulose esters and ethers. Soc. anon. four l'ind. chim. à Bâle. Brit. 338,412, Dec. 22, 1928. Arylaminoanthraquinones are made by heating with H_3BO_3 and a primary aromatic amine the leuco deriv. of a hydroxyanthraquinone, or of an amino or alkylamino deriv. or of a sulfonic acid of any of these compds., in aq. soln. or suspension (or instead of the leuco derivs. the anthraquinone compds. themselves may be used in the presence of a reducing agent). If desired the reaction may be so conducted that any sulfonic groups present in the β-position are completely or partially removed during the condensation. The products are *acid dyes* for animal fibers or for artificial fibers such as "acetate silk," or, if non-sulfonated, for *resins, varnishes* or colloids such as nitrocellulose varnish or cellulose acetate. Several examples are given of the production of dyes giving green and blue colorations.

Aniline-black dyeing on cellulose acetate. Silver Springs Bleaching & Dyeing Co., Ltd. and A. J. Hall. Brit. 337,746, July 27, 1929. Fibers, films, fabrics, etc., comprising cellulose acetate, are treated with a mixt. contg. aniline and at least one org. amine serving as an oxidation catalyst such as *p*-aminodiphenylamine, *p*-phenylenediamine, *p*-aminophenol or nitrosodimethylaniline, followed by oxidation in a hot acidified soln. of a dichromate at least nearly satd. with NaCl. Other amines may be used with the aniline, such as *o*- and *p*-toluidines, *m*-phenylenediamine or α-naphthylamine. Various details of procedure are given.

Thickening agents for dyeing. Ferd. Sichel Komm. Ges. Ger. 514,842, Mar. 2, 1928. A thickening agent is prepared, by pulverizing vegetable mucus with a small quantity of steeped starch.

Dyes and intermediates. I. G. Farbenind. A.-G. (Georg Kränzlein, Heinrich Greune and Max Thiele, inventors). Ger. 517,194, June 7, 1928. See Brit. 313,094 (*C. A.* **24**, 971).

Dyes and intermediates. I. G. Farbenind. A.-G. Brit. 337,860. Aug. 20, 1929. Monoöxamic acids of 4,4′-diaminodiaryl-1,1′-cyclohexane are made by heating with oxalic acid (preferably in the presence of a solvent) parent substances such as 4,4′-diaminodiphenyl-1,1′-cyclohexane, 4,4′-diamino-3,3′-dimethyldiphenyl-1,1′-cyclohexane, 4,4′-diamino-3,3′-dimethoxy-1,1′-cyclohexane, 4,4′-diamino-3,3′-diethoxy-1,1′-cyclohexane, 4,4′-diamino-3,3′-dichloro(or dibromo)-1,1′-cyclohexane or 4,4′-diamino-3,3′-dimethyl-4″-methylcyclohexane. The monoöxamic acids thus formed may be diazotized and coupled with various components to form azo dyes (of which numerous examples are given).

Dye intermediates. I. G. Farbenind. A.-G. Brit. 338,240, Aug. 27, 1929. 4-Aminodiphenylamine derivs. substituted in the 3- or 4′-positions or both, by alkyl, Cl or alkoxy groups are obtained by condensing a *p*-alkyl-, chloro- or alkoxy-substituted or an unsubstituted nitrosobenzene, with an *o*-alkyl-, chloro- or alkoxy-substituted or an unsubstituted nitrosobenzene (at least one nucleus being substituted) and reducing the product (suitably with Na sulfide). Several examples are given.

Dye intermediates. I. G. Farbenind. A.-G. Brit. 338,314, Oct. 18, 1929. Urea derivs. of the general formula (NH—R—CO—NH)$_2$R′—(OH)$_2$CO (in which R and R′ are aromatic residues of the benzene or naphthalene series which may contain substituents but no free sulfonic or carboxylic acid group and in which at least one *o* or *p* position to the OH group is free) are made by condensing a diarylureadicarboxylic acid or the corresponding acid chloride in the presence of a dehydrating agent with an aminophenol. Several examples are given for producing intermediates, the alkali salts of which can be used for impregnating cotton goods for the production of azo dyes on the fiber.

Dye intermediates. I. G. Farbenind. A.-G. Brit. 337,563, Oct. 10, 1929. Azo and azoxy compds. are made by reduction, in alk. soln., of compds. of the general formula HO-aryl-NHCO-aryl-NO$_2$ (in which the aryl radicals may be the same or different and may contain further substituents, and *o*- or *p*-position to the OH group being free and the NO$_2$ group being in *m*- or *p*-position to the CO group). Glucose, Zn dust and Na sulfide are suitable reducing agents. Several examples are given and nitroarylacylaminophenols suitable for use as starting materials are made by condensing *m*- or *p*-nitrobenzoic acid or their halogen, alkyl or alkoxy derivs. with an aminophenol or substitution product, which has a free *o*- or *p*-position to the OH group.

Dye intermediates. I. G. Farbenind. A.-G. Brit. 337,821, Aug. 8, 1929. 3-Methoxytetrahydrocarbazole distd. over Pb oxide at 500–600° gives 3-hydroxycarbazole and, similarly, 2-hydroxycarbazole is obtained from 2-ethoxytetrahydrocarbazole. The starting materials may be obtained by forming hydrazones from the alkoxyphenyl-

hydrazines and cyclohe and effecting ring closure with H_2SO_4 to the corresponding tetrahydrocarbazole.

Dye intermediates. I. G. FARBENIND A.-G. Brit. 337,902, Sept. 18, 1929. Carboxylic acids of aromatic diamino compds. in which both amino groups are nitrobenzoylated or in which one amino group is nitrobenzoylated and the other is either unsubstituted or contains a substituent which is easily eliminated or of mononitrobenzoylated aminonitro compds., are subjected to a slight reduction such as required to convert an aromatic nitro compd. into an azo or azoxy compd. The resulting products may be diazotized and coupled to form azo dyes on the fiber with compds. such as 1-phenyl-3-methyl-5-pyrazolone or β-naphthol. Several examples are given for dyeing various yellow and red shades.

Dyeing and printing fibers. I. G. FARBENIND. A.-G. (Erwin Hoffa and Max Kerth, inventors). Ger. 514,738, Oct. 21, 1927. To produce fast colors on fibers, the fibers are treated with an arylthioglycol-*o*-carboxylic amide of the general formula $H_2NCO.R.SCH_2CO_2H$ and an alkali. Thus, cotton is printed with a paste contg. 5-chloro-1-methylbenzene-3-thioglycolic acid-2-carboxylic amide, water, NaOH, alk. thickening and gum. The thickening contains gum and NaOH in the proportions 1.10. After drying, the cotton is steamed, oxidized and developed in a soln. of $K_3FeC_6N_6$. The resulting colors are fast. Other examples are given. Cf. *C. A.* **24**, 733.

Dyeing cellulose esters and ethers. I. G. FARBENIND. A.-G. Brit. 338,095, April 9, 1930. Deep greenish yellow tints are produced on products such as "acetate silk" by use of compds., non-sulfonated in the nucleus, such as are obtainable by interaction of 4-amino-1,8-naphthalic anhydride with hydrazine or a deriv. or compds. of the same general type. Cf. *C. A.* **25**, 2007.

Dyeing cellulose derivatives. I. G. FARBENIND. A.-G Ger. 514,952, Dec. 19, 1926. In dyeing cellulose derivs., alkylated, arylated or aralkylated ethers or thioethers of the anthraquinone series, contg. no addnl. chromophoric groups, are used. Thus, acetate silk is colored golden yellow, greenish yellow and orange by neutral soap pastes contg., resp., 1,4-dimethoxy-, 1,4,8-trimethoxyanthraquinone and anthraquinone-1,4-dithioldimethyl ether.

Dyeing cellulose acetate. GEORGE H. ELLIS (to Celanese Corp of America) U. S. 1,793,360, Feb. 17. The material is treated with at least one amino compd. such as *p*-aminodiphenylamine from an aq. soln. and is then impregnated with a soln. comprising an oxidizing agent such as a mixt. contg $NaClO_3$ and then, without rinsing, subjected to aging in a warm moist atm

Dyeing regenerated cellulose materials. IMPERIAL CHEMICAL INDUSTRIES, LTD., and R. BRIGHTMAN. Brit. 338,111, July 3, 1929. Level dyeings are produced by use of dyes of any of the three following characters: (1) an aminobenzoylphenylenediamine of the formula $NH_2C_6H_4CONHC_6H_4NH_2$ or a homolog or substitution product of suitable character, tetrazotized and coupled with 1 mol of a 2,8-, 1,8- or 1,5-aminonaphtholsulfonic or disulfonic acid or a *N*-substituted or azo deriv. or aminocyclic aryl or aroyl deriv., contg. no external amino group, of 2,5,7-aminonaphtholsulfonic acid, and with 1 mol. of a coupling component other than 2,5,7-aminonaphtholsulfonic acid or a monocyclic aryl deriv. contg. an external amino group; (2) an aminoacetanilide or a nitroaniline or a substitution product, diazotized and coupled with a component corresponding to one of those specified in "(1)" (which component, when a diazotized aminoacetanilide is used, should not contain an acylamino or unsubstituted amino group, and, when a diazotized nitroaniline is used, should not contain a nitro or unsubstituted amino group), followed by hydrolysis of the acylamino group or reduction of the nitro group, diazotizing of the aminoazo product and coupling to a component such as the other components specified in "(1)"; or, (3) a diazo compd. is coupled with an amine of the benzene series which couples in *p*-position to the amino group, the aminoazo product is condensed with a nitrobenzoyl chloride, the nitro group is reduced, and the product is diazotized and coupled with a 2,8-, 1,8- or 1,5-aminonaphtholsulfonic or -disulfonic acid, or a *N*-substituted or azo deriv. or a monocyclic aryl deriv. contg. no external amino group, of 2,5,7-aminonaphtholsulfonic acid. Numerous examples are given of dyes suitable for use on "viscose silk." Cf. *C. A.* **25**, 1951.

Dyeing threads, etc., with developing dyes. F. KARRER. Brit. 338,012, Nov. 25, 1929. The material in the form of cops or transverse wound bobbins is introduced into a vessel which is filled with grounding liquor and subjected to a vacuum after satn. with the liquid. The vacuum is broken and the liquor removed, and, without removal from the vessel, an intermediate dyeing is effected followed by development. Various details of app. are described.

Dyeing furs, hairs and feathers. KARL MARX and ERICH LEHMANN (to General Aniline Works). U. S. 1,795,133, March 3. In contradistinction to 4-aminodiphenylamine, the salts of the *N*-substituted-4-aminodiphenylamines are easily sol. in water, and they give good gray tints on furs, hair, feathers and the like, even when dyed from a soln. in hard water or from a soln. which is alk. as from the presence of a small quantity of NH_3. Among the substances which may be used are: 4-amino-*N*-methyldiphenylamine, 4-amino-*N*-ethyldiphenylamine, 4-amino-*N*-propyldiphenylamine, 4-amino-*N*-butyldiphenylamine, 4-amino-*N*-benzyldiphenylamine, 4-amino-*N*-ethoxydiphenylamine or corresponding compds. with a substituent in the *p*-position of the benzene nucleus. The fur to be dyed may be treated with a mordant. The *N*-substituted amines may be manufd. by subjecting the *N*-substituted diphenylamines to nitration and subsequent reduction.

Dyeing and printing textiles. I. G. FARBENIND. A.-G. Brit. 337,846, Aug. 13, 1929. Acid amides or esters obtainable from vat dyes or their leuco compds. as described in Brit. 324,119 (*C. A.* **24**, 3380) or Brit. 330,579 (*C. A.* **24**, 6032) are used for dyeing or printing and development is effected with alk. agents (some of which may be added to the thickening in printing cotton so that partial development is effected by moist steaming). Several examples are given.

Dyeing and printing textiles. MANCHESTER OXIDE CO., LTD. Ger. 514,953, June 29, 1928. See Brit. 296,530 (*C. A.* **23**, 2580) and Fr. 656,827 (*C. A.* **23**, 4350).

Mordanting, weighting and metallizing textile materials, films, etc. BRITISH CELANESE, LTD., W. A. DICKIE and F. B. HILL. Brit. 337,813, Aug. 7, 1929. Metals such as Al, Sn or Zn or alloys of lake-forming and other metals, are applied (intermittently or in the form of a pattern if desired) by an app. such as a Schoop metallizing app., to textile materials, films or the like and the metal may then be oxidized on the material if not sufficiently oxidized during its application. In mordanting by this method, the dye may be applied before or after the mordant or at the same time with it as by spraying through a stencil. In treating materials of cellulose esters or ethers, the dye is preferably used together with an org. solvent. Various details and modifications of procedure are described.

Coloring plastic masses or their solutions. I. G. FARBENIND. A.-G. (Werner Müller, Karl Holzach and Hans Krzikalla, inventors). Ger. 517,491, May 26, 1929. Celluloid, cellulose esters or ethers, natural or synthetic resins and other plastic masses or their solns., are colored by incorporating into them sol. Cr or Cu compds. of dyes, particularly *o*-hydroxyazo dyes. Solns. in org. solvents of the dye compd. and the celluloid, etc., may be mixed, or the materials may be kneaded together on rolls. Examples are given.

Acid baths in dyeing. I. G. FARBENIND. A. G. (Josef Nüsslein and Josef Stadler, inventors). Ger. 514,801, May 16, 1929. Addn. to 466,420 (*C. A.* **23**, 529). Instead of the soap or Turkey-red oil of 466,420, other soap like substances are added to the dye baths. Thus, a soln. of olein in ethyl ether of polyglycol is stirred with isopropylated Na naphthalenesulfonate. The product congeals into a clear soln. and is used in acid dye baths. Butylated naphthalenesulfonic acid or its salts, or sulfite cellulose lye may be used.

Fabric printing machine. JOHN WALDRON CORP. Ger. 514,950, Aug. 9, 1928.

Dye vat and jigger apparatus. F. HEWITT. Brit. 337,804, Sept. 12, 1929. Structural features.

Apparatus for dyeing tubular packages of textile threads. J. BRANDWOOD. Brit. 338,134, Aug. 7, 1929. Various details of construction and operation are described.

Apparatus for dyeing thread or yarn in packages. CHARLES K. DUNLAP (to Sonoco Products Co.). U. S. 1,703,736, Feb. 24. Structural features.

Apparatus for passing woven fabrics through dyeing, washing or bleaching baths, etc. CHARLES G. HANHART (to Farbetei Weidmann A.-G.). U. S. 1,794,403, March 3. Structural features.

Apparatus for applying sizing, dyeing or dressing liquids etc., to, cellulose acetate or other yarns. BRITISH CELANESE, LTD., and W. I. TAYLOR. Brit. 337,433, May 30, 1929. Structural features.

Treating fabrics. EDUARD TSCHÖRNER and HEINRICH RIBS. Ger. 514,951, Aug. 25, 1928. Pile fabric is prepd. for cutting by treating the weft with an alk. soap soln. or a soln. of alkali with sulfonated oil, to which an oxidizing agent, such as Na_2IO_3, Na_2O_2 or H_2O_2, is added.

Impregnating textiles. GIULIA KNÖZINGER and LEO KNÖZINGER. Ger. 517,174, Oct. 9, 1928. Textile materials are strengthened and given a weighty appearance by

applying a suspension of kaolin or $BaSO_4$ in glue The treatment is particularly intended for theatrical accessories, decorations, etc.

Retting flax with yeast and sulfurous acid. MARTIN WADDELL and HENRY C. WATSON. Ger. 517,100, Oct. 20, 1927. See U. S. 1,708,812 (*C. A.* **23**, 2582).

Bleaching jute fiber. J. BERLINERBLAU. Brit. 337,986, Nov. 22, 1928. Jute fiber is moistened with acid such as a 2-3% HCl soln. and treated with SO_2 at normal pressure to brighten its color while retaining its natural tint and gloss.

Fibers. FIRMA A MONFORTS Ger. 514,706, Nov. 27, 1927. Yarn, cord, etc., made from hard fibers such as manilla, etc., is smoothed and polished by treating with rubber or rubber soln., and with a mineral lubricant such as talcum.

Mercerizing fabrics. C. MOCKER. Brit. 337,646, Dec. 6, 1929. The fabrics are subjected to a series of baths of increasing concns. and gradually decreasing temps., detd. continuously by the shrinkage or elongation of the fabric during treatment, maintained in counterflow to the movement of the fabric and suitably replenished. App. is described.

Zig-zag roller apparatus for mercerizing fabrics. O. HOFFMANN. Brit. 337,712, March 10, 1930. Structural features.

Preventing creasing in liquid treatments of textile materials. BRITISH CELANESE, LTD. and G. H. ELLIS. Brit. 338,190, Aug. 13, 1929. In treating materials such as those of cellulose acetate or other cellulose esters or ethers made by dry-spinning processes, with scouring, dyeing or other liquids, in folded form as in winch machines, creasing is avoided by first wetting out the material thoroughly in open width form. Various wetting agents are mentioned as suitable and this treatment may be combined with other treatments such as delustering with a hot soap soln.

Steaming printed textile fabrics. I G FARBENIND. A.-G. Brit. 336,590, March 18, 1929. A steaming process as described in Brit 333,873 (for reducing printed fabrics by passing steam from the lower part of a vessel up through the fabric surrounded with a protective filling material such as sand) is applied to various printed or dyed fabrics.

Bleaching materials such as linen. O. HOFFMANN. Brit. 337,305, Feb. 9, 1929. The material is uniformly and moderately moistened and then kept in constant and uniform movement (as by passing fabric in a zig-zag path over rollers) while exposed to a low concn. of ozone (not over 2 g. per cu.m. of air and preferably a much lower concn.). App. and various details of procedure are described

Delustering artificial threads and filaments. COURTAULDS, LTD., and C. DIAMOND. Brit. 338,269, Sept. 16, 1929. Products such as those formed from cellulose acetate (suitably by dry spinning in acetone contg 1% of Arachis oil) are treated with aq. soap soln. at or near the b. p.

Improving elasticity of knitted artificial silk fabrics, etc. COMFOLASTIC CORP. Brit 337,400, Nov. 2, 1928. The material is stretched while moist (as after dyeing), in one direction, allowed to dry in stretched condition, and a sheet of rubber is vulcanized on one face of the fabric. The material is suitable for making waist bands, garters, etc.

Waterproofing fabrics. BRITISH CELANESE, LTD. Brit. 338,065, Jan. 15, 1929. A material suitable for raincoats or bathing-suit bags comprises a fabric base having on it a layer of rubber compn. and also a layer of a cellulose ester or cellulose ether compn. together with a compatible synthetic resin Various examples of materials used are given, and plasticizers, coloring agents, etc., may be added.

Waterproofing wool. MERKEL & KIENLIN GES. Brit. 338,391, Dec. 13, 1928. Waterproofing is effected by treating the material first with an aq. emulsion contg. soap and an oil or fat of animal or vegetable origin (suitably olive oil) and then with a soln. of salts of those metals the hydroxides and carbonates of which are insol. or but slightly sol. in water, such as Al formate, and subsequently heating to 60–80° for some time.

Carbonizing wool. I. G. FARBENIND. A.-G (Albrecht Kittel, Carl Daimler and Gerhard Balle, inventors). Ger. 517,201, Jan. 11, 1925. In carbonizing wool with H_2SO_4, an aromatic sulfonic acid having a tanning action, or a salt of such acid, is added to the bath. A bath of lower H_2SO_4 content than is usual can then be used. An example is given.

Forming yarns and threads of impregnated fibers. L. S. M. LEJEUNE and J. E. C. BONGRAND. Brit. 338,381, Nov. 25, 1929. Fibers such as cotton, wool, silk, flax, hemp, ramie, etc., are impregnated with solns., suspensions or dispersions of materials such as rubber, rubber-like substances or synthetic resins on the spinning-frame when the fibers are in the roving stage and before twisting into thread. Numerous details of app. and procedure are described.

Imitation linen, etc. E. O. MUNKTELL. Brit. 338,224, Aug. 20, 1929. Imitation linen, towels, handkerchiefs, etc., are made by pressing superposed layers of cellulose wadding material, which may be replaced wholly or in part by Japanese yoshino paper or the like, some of the layers of which are impregnated more strongly than others with waterproofing or sizing agents, etc., such as compns. comprising cellulose esters, gelatin, glue, paraffin oil or wax, starch, borax, Japan wax, casein, resin glue, etc., in various mixts. Goffering is usually effected simultaneously with the pressing.

Plaited fabric containing cellulose acetate yarns. CAMILLE DREYFUS. U. S. 1,793,915, Feb. 24. The material is subjected to a plaiting operation in the presence of a softening agent for the cellulose acetate such as aq. acetone soln. in order to render the plaiting permanent.

Washing materials with soap-forming substances. A. MARQUARDT and E. WALTER. Brit. 338,121, Aug. 8, 1929. In a combined soap-forming and cleansing process, the materials of soap-forming character are added together or successively to the wash without previous pressing into the articles to be washed and without pressing out of the liquid, and alcs., hydrocarbons, colloids, ferments, bleaching agents, etc., also may be added. Carbonates may be used for saponifying fatty substances and for liberating gas which assists in the cleansing. Numerous details and modifications of treatment are described. Cf. *C. A.* 24, 3869.

Edging fabrics to prevent fraying. TILLIE MILLER. U. S. 1,793,630, Feb. 24. Various details are described of a treatment involving the application of a metallic material (such as a mixt. of shellac, rosin, stearic acid and Al bronze) to the edge of the fabric so that it serves as a binder when it solidifies.

Material for "jacquard" cylinders of looms. MILES J. SMITH and HERBERT CHILSON (to Carolina Rubber Co.). U. S. 1,793,722, Feb. 24. A compn. is used formed of clean thin brown rubber 35, ZnO 10, "Dixie clay" 25, "Cycline oil" 3, lime an accelerator 0.4 and S 15 parts, cured by heating. Various details of manufacture described.

Transferring pictures to fabrics. A. DENGLER. Brit. 337,877, Nov. 3, 1929. Pictures fast to light and to washing are applied to fabrics by a transfer comprising a paper backing carrying a paste contg. colors and mordants which only commence to interact under the influence of heat and moisture applied in the transferring. K perearbonate may be added to a cooled soln. of gelatin and this soln. added to an aq. soln. of com. Na phosphate contg. indigo. Various other substances are mentioned which may be used.

Gasproof fabric suitable for aircraft gas cells. JOHN B. FLOWERS. U. S. 1,793,075, Feb. 17. Alternate layers of rubber cement and metal leaf are applied to a fabric and each layer of cement is allowed to dry until tacky before applying the metal leaf and to harden before applying the next layer of cement. The metal leaf is applied in sheets which are overlapped.

Treating fibrous materials with rubber, etc. F. T. LAHEY. Brit. 337,359, June 19, 1929. Animal or vegetable fibers, either combed or in the form of batting, yarn or cloth are cleaned, mordanted with a latex coagulating substance, and then treated with a natural or artificial dispersion of rubber which may be assocd. with linseed oil, and various compounding, pore-forming or other substances for making *artificial leathers, tire fabrics, floor coverings, insulation*, etc. Cf. *C. A.* 24, 4406.

Rubber-coated fabric. JOHN R. COUTURE (to E. I. du Pont de Nemours & Co.). U. S. 1,795,199, March 3. A material suitable for automobile tops comprises a textile fabric coated with rubber and provided with an overlying coating of baked petroleum asphalt varnish. Cf. *C. A.* 24, 1524.

Protein products resembling wool, hair, horn, etc. SOC. D'APPLICATIONS DES RECHERCHES SCIENTIFIQUES ET INDUSTRIELLES (S. A. R. S. I.). Brit. 338,014, Oct. 24, 1928. Materials such as gelatin, chondrin, albumin, casein and gelose are treated with an alkali or alk. earth metal thiosulfate in the presence of an acid or salt (such as an alum) which decomposes the thiosulfate and liberates S in a colloidal or finely divided state within the mass. The material may be successively and alternately treated with reagents of this character until the entire mass is insol. in hot water and swells but little, and may be subjected to a preliminary treatment or subsequent treatment with substances such as formal, Na borate, a dichromate, picric or pyrogallic acid, tannin or alum to impart insoly. and impermeability to the material, and may be rendered more flexible by treatment with a final bath such as one contg. glycerol or molasses or a plasticizing agent. Cf. *C. A.* 24, 3868.

Protecting wool, fur, hair, etc., from "textile pests." I. G. FARBENIND. A. G. Brit. 337,823, Aug. 8, 1929. The materials are treated with solns. of as phenyl

caproylpseudothiourea, *as*-phenylvalerylthiourea, acetylallylthiourea or other thiourea derivs. of the same general type.

Halogenated hydroxy-di- and tri-arylmethanes. I. G. FARBENIND. A.-G. Brit. 337,832, Aug. 9, 1929. Products suitable for mothproofing wool, furs, etc., are obtained by condensation of an aldehyde deriv. in which the carbonyl O is replaced by alkyloxy or inorg. or org. acid residues, with a *p*-halogenated phenol contg. a free *o*-position to a OH group but which may be substituted in the other positions by "indifferent" substituents such as halogens or alkyl groups. The products may be used as addns. to dye baths. Among the starting materials which may be used are: (1) methylal, methylenediacetate or the dimethylacetal of *o*-chlorobenzaldehyde, condensed with *p*-chlorophenol; (2) 2,4-dichlorophenol condensed with the acetal-like chlorides and sulfates produced by adding benzal chloride, 2,6-dichlorobenzal chloride or 2-chlorobenzal chloride to H_2SO_4; (3) 2-chloro-, 4-chloro-, 2,6-dichloro-, 4-chloro-2-sulfo- or 5-chloro-2-sulfobenzal chloride condensed with *p*-chlorophenol, 2,4-dichlorophenol or mixts of *p*-halogenated phenols; (4) *p*-chlorophenol condensed with the chloride obtained by treating *o*-sulfobenzaldehyde with PCl_5. Condensing agents such as H_2SO_4, chlorides of Zn, Fe or Al or a mixt. of HCl and glacial HOAc may be used and the condensation may be effected in solvents such as PhCl or $PhNO_2$. 4-Chloro- and 5-chlorosulfobenzaldehydes are prepd. by treating the corresponding benzaldehyde with PCl_5.

Sulfonated hydroxyarylmethanes. I. G. FARBENIND. A.-G. Brit. 337,808, Aug. 6, 1929. Hydroxy-di- and tri-arylmethanes, prepd. as described in Brit. 316,900 (*C.* **1** 24, 1993); Brit. 333,561 (*C. A.* **25**, 607); Brit. 330,893 and Brit. 330,894 (*C. A.* **24**, 6036); Brit. 335,547 (*C. A.* **25**, 1687); Brit. 337,832 (preceding abstr.) and Brit. 338,126 (following abstr.), are sulfonated (suitably in the presence of org. solvents, and the products thus obtained may be used for *protecting furs, wool, etc., from moths* (being used conjointly with a dye bath if desired). Various details and examples are given.

Brominated and chlorinated *o*-hydroxy-di- and tri-arylmethanes. I. G. FARBENIND. A.-G. Brit. 338,126, Aug. 9, 1929. Compds. of this character are prepd. by brominating or chlorinating the corresponding parent materials, and are suitable for use in *mothproofing wool, fur, hair*, etc., and for this purpose may be added to dye baths. Examples are given of the prepn. of 2,2′-dihydroxy-5,5′-dichlorodiphenylmethane, 2-hydroxy-3,5-dibromodiphenylmethane, 3,5-dichloro-2-hydroxydiphenylmethane and some similar compds.

Wetting agents. I. G. FARBENIND. A.-G. Brit. 337,737, April 27, 1929. Monoamines contg. only one hydroxyalkyl group and free from aromatic groups are condensed with aliphatic carboxylic, sulfonic or sulfonated carboxylic acids contg. at least 8 C atoms or their esters or halides (at a temp. above 100° when the free acids or their esters are used) and the products may be treated with alkylating agents and (being usually basic in character) may be converted into salts with acids. Numerous details and examples are given for prepg. compns. which may be used as wetting, emulsifying, cleansing and dispersing agents in the textile industry, etc. Cf. *C. A.* **24**, 1947, 4906.

Apparatus for degreasing clothes by treatment with solvents. MAURICE DEW. HIRST (one-half to Leroy A. Goodwin). U. S. 1,795,170, March 3. Structural features.

Bag filter for filtering garment-cleaning solvents or other liquids. ANTON L. DORFNER. U. S. 1,794,281, Feb. 24.

Apparatus for purifying garment-cleaning liquids by materials such as saponifying agents and water. CLARENCE V. FUQUA (to Cleaners Equipment Corp.). U. S. 1,793,475, Feb. 24. Structural features.

26 PAINTS, VARNISHES AND RESINS

A. H. SABIN

Additional field tests on quick-drying paints. H. A. GARDNER AND L. P. HART. *Proc. Paint & Varnish Mfrs' Assoc.* Circ. No. 377, 113–9(1931).—The formulas of 20 spar paints supplementing those reported in *C. A.* **25**, 1104 are given. G. G. S.

Rapid methods for detecting with organic reagents the metals used in the paint industry. HANS SCHEIBER. *Farbe u. Lack.* **1931**, 111–2.—Methods are compiled for the detection of Fe, Al, Mn, Co, Zn and Mg. G. G. SWARD

Experiences in painting façades (plaster). HANS WOLFF. *Farbe u. Lack.* **1931**, 101–100.—Regardless of the type of material (aq. or non-aq.) used to paint plaster, water must be excluded after the coating is in place. If water does not destroy the film

itself, it promotes efflorescence, permits growth of molds, collection of soot, etc. Spraying a painted surface with a colloidal soln. of paraffin (Schmidt's encaustic process) is effective in excluding water. G. G. SWARD

The preparation of precipitated white lead with high hiding power. A. I. KOGAN. *Farben-Ztg.* **36**, 826–8(1931).—White lead prepd. by pptn. from a basic Pb acetate soln. by CO_2 is low in hiding power because of the formation of considerable $PbCO_3$. When CO_2 is passed through a basic lead acetate soln., $2Pb(OH)_2 \cdot PbCO_3$ is formed in the early stages. Later $PbCO_3$ is also formed at the expense of some of the basic carbonate already formed. If the process is stopped in the early stages a pigment of high hiding power is obtained. This ppt. may be removed and the process repeated several times. Hiding-power values for the pigment obtained in the improved manner ranged from 22.4 to 29.3 sq. cm./g. as compared with 15.3 sq. cm./g. for the complete pptn. method. The sp. gr. ranged from 5.95 to 6.26. G. G. SWARD

The red lead question. A. V. BLOM. *Farben-Ztg* **36**, 1045–6(1931).—The reaction of linseed oil with red lead is governed not only by the particle size and percentage of PbO, but also by the cryst. structure of the PbO. *E. g.*, flat plates and spheres are less reactive than irregular crystals or clusters. The form which is ideal for non reactivity is a kernal of PbO surrounded by small spheres of Pb_3O_4. G. G. SWARD

Adulteration of red lead and chrome green. E. DINSLAGE AND B. STEMPEL. *Pharm. Ztg.* **76**, 262(1931).—Red lead (minium) was found admixed with heavy spar ($BaSO_4$) colored with an aniline dye. Chrome green (normally a mixt. of oxides of Cr) carried $PbCrO_4$ and $BaSO_4$. W. O. E.

The colorimetry of pigments and a suggested scale of fastness. G. F. NIX, G. S. DISNEY AND D. L. TILLEARD. *J. Oil & Colour Chem. Assoc.* **14**, 3–48(1931). A method for quantitatively measuring the extent of fading of colored surfaces is given. The color quality before and after fading is located on the trichromatic color chart. The length in color triangle units (C. T. U.) of the line connecting these loci is then plotted against the time of fading. In most comparisons brightness need not be considered. Colors of different hues, satn. and brightness may be directly compared. According to their fastness pigments and dyestuffs may be placed in 10 or more groups, group 1 being the most stable with a fading line of 1 to 1.33 C. T. U. for 75 hrs.' exposure to a C arc. The lengths of the fading lines of successive groups bear a ratio of 2. Examples of the fading of red pigments diluted with white pigments are given. The study of the color characteristics of pigments is best made at a dilution of 9 parts of diluent. The medium recommended is a 1% soln. of gelatin in H_2O in such quantity that not more than 0.5% of the film is gelatin. A discussion follows. G. G. S.

Fastness of pigment finish to rubbing. M. C. LAMB AND R. DENYER. *J. Internat. Soc. Leather Trades Chem.* **15**, 107–13(1931). The whole question of the manufacture of pigment finishes is critically considered. Suitable grinding media for pigments are soap solns., sulfonated oils, and solubilized mineral oils. Pigments ground in soap oils possess exceptional covering power and stability in suspension. Pigments should not be allowed to dry before mixing with the binder. NH_4OH is preferred to borax or soda for dissolving casein or shellac to be used as a binder, since the excess NH_3 is evolved on drying and the resulting deposit is more waterproof. Since a finish containing only shellac-casein-ammonia-pigment would be too brittle, various gums are added. Casein (and other protein binders) are made insol. by HCHO, but the resulting finish is brittle and available softening agents are not very satisfactory. *Tung oil* seems to be an excellent binder. The following tentative procedure is suggested: Add 1–2 parts tung oil to 10 parts soap dissolved in 250 parts water (not over 60°), emulsify, let stand 24 hrs., add 250 parts H_2O, emulsify, add 100 parts dry pigment and grind until the pigment is sufficiently fine. Mix this pigment emulsion with (1) a soln. conts. 1% casein and 1% com. NH_4OH, (2) a 10% soln. of glue and (3) glycerol, in the proportions 15:30:25.8. Sterilize with about 0.13% nitrobenzene. Apply by spraying, and top off with HCHO soln. H. B. MERKEL

Pigments and lacquers from organic coloring materials. A. SANDER. *Angew. chimica* **5**, 1490–5(1930).—A brief summary of the history, classification, theory, prepn., use and analysis of org. dyestuffs. A. W. CONTIERI

Reactions between inorganic basic pigments and linseed oil. K. CHARISIUS AND E. KINDSCHER. *Farben-Ztg.* **36**, 780–3(1931); cf. *C. A.* **24**, 3913–4.—Equal apparent vols. of ZnO, basic Pb carbonate, basic Pb sulfate, highly disperse red lead, ordinary red lead and litharge were each suspended in raw linseed oil in the absence of air. The reaction of the oil with the pigments was essentially the same as in systems in which air was not excluded, *viz.*, large amts. of metal were found in the oil in ordinary red lead and litharge and relatively small quantities in the other pigments. G. G. S.

Some properties of pigment-oil pastes. W. Droste. *Farben-Ztg.* **36**, 916–8 (1931); cf. *C. A.* **25**, 831.—The relationship between the oil absorption of pigments and the consistency of paint is reviewed. G. G. Sward

Application of a few colloid-chemical methods of investigation to the drying of linseed oil. H. Freundlich and H. W. Albu. *Z. angew. Chem.* **44**, 56–60(1931).—Depolarization expts. as well as viscosity measurements and ultramicroscopic examn. show that at a low drying rate colloidal properties are not obtained in pure or siccative linseed oil. H. Stoertz

The drying time of linseed oil. J. Rinse. *Chem. Weekblad* **28**, 131–2(1931).—The influence of the humidity and other factors of the atm. on the drying time of linseed oil is discussed. E. Schotte

Tung-oil tree. Wilmon Newell, Harold Mowry and R. M. Barnette. Fla. Agr. Expt. Sta., *Bull.* **221**, 5–63(1930); cf. *C. A.* **24**, 1526.—The Fla. acreage in tung-oil trees is about 5000. The fruits on examn. gave 55% hulls, 45% meat, 49% oil in the meat and 32 9% of oil in the seeds. Fully matured and thoroughly air-dried fruits consist of approx. 56% seed and 44% hulls. The tree thrives best in an acid, well-drained soil. Lack of N in the soil is the principal limiting growth factor in Fla. but a well-balanced mixed fertilizer gives max. growth and yields of nuts. A tung-oil expression plant is located at Gainesville The oil is graded as cold Pressed Fla. No. 1 and Fla. No. 2. The appearance of the former is pale and clear with a sp. gr. at 15.5° of 0.941, acid no. 0.5, sapon. no. 193 8, I no. 166, A. S. T. M. heat test 10.75, and n_{25} 1.519. Hulls and pomace remain after extn. of the oil. Pomace contains about 6% of N and compares favorably with castor-bean pomace as a *fertilizer*. The hulls contain a little N and K and are valuable chiefly as a mulching material. For *varnish manuf.*, the oil gives a clearer and faster drying finish than the ordinary imported Chinese oil. C. R. Fellers

Reactivity of mineral umbers with oils. A. Eibner, Richard Schwarz and E. Rossmann. *Farben-Ztg.* **36**, 962–4, 1006–7, 1046–9(1931).—The formation of soaps in mixts. of pigments and drying oils is usually due to the presence of the original fatty acids. Only a few pigments, *e. g.*, red lead, are able to react with glycerides under the conditions of storage and drying usually prevailing The principal requirement is an elevated temp. If a reaction does occur, the products are mixts. of normal soaps and mixed glycerides of the metal, the so-called aggregates. Such a reaction should not be called sapon. With 2 umbers, no reaction took place with either linseed oil or poppyseed oil until resins were added. This indicates greater reactivity of resin acids than of fatty acids. Metal aggregates improve not only the drying but also the durability of paints. Under certain conditions linseed and poppyseed oils, and presumably all other drying oils, yield H_2O soluble cryst. compds. of a peroxide nature. With further oxidation, the cryst. character is destroyed. Such a reaction in the drying of oils is contrary to Auer's theory. C. G. Sward

Lacquer poisoning. G. Ohnesorge. *Deut. med. Wochschr.* **56**, 961–3(1930).—Several cases of poisoning among workers in a hat factory were traced to the *action of tetrachloroethane.* Arthur Grollman

Nitrocellulose lacquers in the wood-working industry. Prillwitz. *Nitrocellulose* **2**, 8–10(1931). E. M. Symmes

Alcohol-soluble nitrocellulose. Hans Wolff and B. Rosen. *Farben-Ztg.* **36**, 964–6(1931).—The hardness, abrasion resistance, tensile strength, elongation and resistance to pressure of a no. of alc.-sol. nitrocelluloses were detd. Better properties were exhibited by those samples possessing the highest viscosities. G. G. Sward

New method for examination of pictures. A. M. de Wild. *Chem. Weekblad* **28**, 126–8(1931); cf. *C. A.* **24**, 739.—A summary of the scientific methods of picture examn. developed during the last 3 years. Chem. analysis can det with certainty the period in which a painting was made. Röntgen-ray examn. is a valuable method for the detection of technical particulars about a certain painter. The method of magnified photographs and photography with grazing light need too much of a subjective interpretation yet to give conclusive and convincing results. E. Schotte

Determining the roughness of a surface. K. Wurth. *Farben-Ztg.* **36**, 875–6 (1931).—Since the amt. of paint required to cover a surface depends upon the roughness as well as the porosity, a method of detg. roughness is desirable. W. does this by making an impression of the surface on tinfoil. G. G. Sward

Rosin used to produce rosin oil. V. E. Grotlisch. *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 834–8(1930).—Rosin oil is produced by distg. 6500–12,000 lb. of rosin, usually of a dark or opaque grade, in a cast-Fe or steel still. Water is first liberated. Rosin spirits (pinolin) begin to distil at 160°, "light oil" at 200°, "kidney

oil" at 250° and "bloom oil" at 270°. The "kidney oil" is the most valuable fraction. It is used in the manuf. of greases and printing inks, and may be redistd. to give the higher-grade oils. Other uses of rosin oils are listed. "Synthetic" rosin oils are soln. of rosin in mineral oils. H. K. SALZBERG

Rosin in the manufacture of rosin esters. STEPHEN BABCOCK. *Proc. Am. Soc Testing Materials* 30, Pt. II, 795-7(1930).—The discussion is limited to ester gum, its history and manuf., and the properties of rosin which are important in its manuf Wood oil-ester gum combinations are popular because they require relatively little time to age. Clean rosin of a clear grade having a high m. p. and acid no. is desirable in manufg. ester gum. H. K. SALZBERG

Tests on oil cloth and artificial leather. R. HESSE. *Nitrocellulose* 2, 6-8(1931) Detailed methods of proximate analysis are given. E. M. SYMMES

Rosin as a linoleum component. M. K. BARE. *Proc. Am. Soc. Testing Materials* 30, Pt. II, 803-6(1930).—Since 1926 the use of rosin by the linoleum industry has increased by 31%. At present this industry ranks fourth in the consumption of rosin Linoleum cement, which is made from wood rosin, accounts for 90% of the total rosin used by the industry The remainder, gum rosin, goes into linoleum paint. Linoleum binder consists of oxidized linseed oil, rosin and other resins. The rosin serves as a solvent for the oxidized oil, its solvent power being greater the higher its acid no. A rosin of very high acid no. cannot be used, however, because of its high m. p. and susceptibility to attack by alkali. The presence of rosin in the binder gives it heat sensitiveness, enabling it to be worked under the compounding machines. Rosin also serves to keep the finished linoleum in a flexible condition. Substitutes for rosin are deficient in this stabilizing effect. H. K. SALZBERG

Fire, explosion and health hazards with nitrocellulose lacquers (GREMPE 24. ... resins of jack pine (PHILLIPS) 23. Solvents (DURRANS) 2. Solvents for resins ... pat. 517,097) 13. Synth... rubber [for addition to paints or lacquers] (Brit. pat. 338,152) 30. Discharge de... [apparatus for atomizing paints with CO_2] (U. S. pat. 1,794,185) 1.

BIANCHI, CALISTO. **Celluloseesterlacke.** Revised German ed. by Adolf W... Berlin: J. Springer. 328 pp. Bound, M. 22.50. Reviewed in *Chem. Trade J.* 88, 2... (1931).

Paints. A. ROGLER Brit. 337,523, Sept. 5, 1929 Paints which dry rapidly are made by heating, drying or semi-drying oils such as linseed, poppyseed or wood oil with metal oxides such as those of Zn or Ti, to about 100-150° until a pasty product is formed, and mixing the latter with solvent and pigments Resins may be added

Paints containing finely divided metals. L. V. ADAMS (to British Thomson Houston Co., Ltd.). Brit. 337,682, Jan. 11, 1929. Metal powders such as Al, Zn, Cu alloys (bronzes), Ag or Au are suspended in a soln. comprising a volatile solvent and a synthetic resin compn. such as one formed from glycerol, phthalic anhydride, linseed oil fatty acids, wood oil, resin and diethylene glycol. Paints thus formed contg. Zn or Al may be applied to base metals such as iron or Cu and the Zn or Al subsequently alloyed with the coated base metal surface by heating.

Apparatus for mixing ingredients of paints, etc. I. I. BAGROV. Brit. 337,915, Oct. 21, 1929. The materials to be mixed are passed under pressure through a pipe coiled in roll of metal net (suitably of 25-35 mesh and about a meter long).

Pigment. SOC. ANON. POUR L'IND. CHIM. À BÂLE Swiss 141,886, Aug. 21, ... A colored pigment is prepd. by mixing chalk or other similar Ca compds. with the azo dye produced by the action of $COCl_2$ on the sapond. dye from the diazotized *p* tolu... sulfonic acid ester of 1,8-aminonaphthol-3,6-disulfonic acid and cresidine, 1,4-... $(MeO)(NH_2)C_6H_3$. The resulting pigment is red and has good light-, water- and w... resisting power. Examples are given.

Iron oxide pigment. JULIUS LAUX (to I. G. Farbenind. A.-G.). U. S. 1,7... Feb. 24. An aromatic nitro compd. such as $PhNO_2$ is reduced with Fe and an ac... contg. at least 25% of a salt of an org. amino compd. such as $PhNH_2$.HCl, and the re... sulting Fe oxide sludge is sepd. from the aromatic amino compd. produced and p... fied by washing. U. S. 1,793,942 relates to a process in which an aromatic nitro compd such as $PhNO_2$ is reduced with Fe and an aq. soln. of acid such as HCl contg. at last 2 mols. of anhyd. acid in 1000 parts of soln., insufficient in quantity to dissolve the Fe,

the sludge formed being sepd. from the resulting amino compd. and purified by washing. Cf. *C. A.* **24**, 5171.

Drying oil. IRVIN W. HUMPHREY (to Hercules Powder Co). U. S. 1,793,220, Feb. 17. A drying oil suitable for use instead of linseed oil comprises a polymerized terpene product composed mainly of polymers having a higher b. p. range than that of the polymer $(C_{10}H_{16})_2$.

Modifying the physical properties of fatty oils. L. AUER. Brit. 337,736, April 24, 1929. For producing a modified product sol. in a desired org. solvent for the manuf. of *"leather cloth," lacquer* or *varnish*, the fatty oil is treated with a modifying agent insol. in the selected solvent, and there is heated with the material over 2% of a soly.-promoting agent such as phenols or ketones; *e. g.*, linseed oil heated with CaO_2 and $ZnSO_3$ produces when the product is dissolved in turpentine a varnish too viscous for use, but a suitably reduced viscosity may be attained by adding about 4% of *o*-nitrophenol or benzoic acid to the modifying agents. The modified products may be used as softening agents with nitrocellulose. Products sol. in acetone or benzene are obtained by heating castor oil with Li_2CO_3 or Li sulfite to which *p*-cresol has been added. Cf. *C. A.* **24**, 2910.

Varnish. "CIRINE-WERKE" JOSEF LORENZ & Co. Swiss 142,167, April 18, 1929. A weather- and acid-proof varnish is made by pulverizing a composition made from several varieties of wax, cold-emulsifying with a dry vegetable oil and mixing with a soln. of Co linoleate in dry vegetable oil and a wax solvent. Thus, bees-, carnauba, mineral and shellac wax are ground up and emulsified with linseed oil. A paste of Co linoleate and linseed or wood oil and C_6H_6 is then added.

Varnish bases. BAKELITE G. M. B. H. (Fritz Seebach, inventor). Ger. 517,445, Feb. 26, 1929. Phenol-aldehyde condensation products capable of being hardened are combined with partly or completely oxidized drying oils. The materials may be combined in soln. and the solvent then evapd. The process may be effected in the presence of an O-carrier, and the oil may be oxidized *in situ*. Examples are given.

Lacquers. KAZUO TAKEMURA and KAZUE OIWA. Ger. 517,349, Aug. 15, 1926. Nitrocellulose is dissolved in AcOAm, Et_2O and acetone, and the soln. is dild. with EtOH and Bu tartrate. $K_4Fe(CN)_6$ and powd. bamboo cane are then incorporated.

Oil lacs. I. G. FARBENIND. A.-G. (Karl Ott and Hanns Bernard, inventors). Ger. 514,914, Sept. 11, 1927. See Fr. 660,748 (*C. A.* **24**, 252).

Non-inflammable nitrocellulose lacquer. MARKUS THAU. U. S. 1,793,726, Feb. 24. CCl_4 is added to a soln. of nitrocellulose in a solvent mixt. such as BuOAc and turpentine.

Coating sheet materials such as wallboard with enamel. JOHN W. COWELL. U. S. 1,793,437, Feb. 17. Mech. features.

Coating metal foil. STAINOLFABRIK BURGDORF A.-G. Brit. 338,340, Oct. 9, 1929. Sn or other foil is coated with a soln. of nitrocellulose in Et lactate and alc., an alc. shellac soln. and castor oil, with or without AmOAc.

Impregnating porous materials. ADOLF KANZOK. Swiss 141,109, Jan. 2, 1928. The materials are soaked in a liquid contg. a phenolic soln. of a substance which will not react with the phenol on forming synthetic resin, but which will promote the polymerization of the phenolic resin. Thus, wood is steeped in a mixt. of aldehyde-NH_3 and cresol, and heated to about 100°. The aldehyde and cresol form a synthetic resin which later polymerizes under the contact action of the NH_3.

Films of cellulose esters or ethers, etc., suitable for tipping cigarets. CHEMISCHE FABRIK VON HEYDEN A.-G. Brit. 337,501, Feb. 15, 1929. Thin bands are formed comprising 2 continuous layers of cellulose esters or ethers such as cellulose acetate and ethyl or benzyl cellulose or the like, one layer contg. a pigment such as a metal powder while the other layer contains a material such as powd. magnesia, lithopone, powd. cellulose or cork which enhances its affinity for adhesives. Various details of manuf. are described.

Revivifying decolorizing clays containing rosin impurities. ROBERT C. PALMER (to Newport Co.). U. S. 1,794,537, March 3. Clay such as that which has been used for purifying rosin is treated with a mixt. of alc. and an org. solvent such as petroleum naphtha to dissolve the impurities in the clay, and the soln. thus formed is displaced from the clay with an org. alc. solvent such as a further quantity of petroleum naphtha.

Revivifying fuller's earth contaminated with rosin impurities. ROBERT C. PALMER. U. S. 1,794,539, March 3. Fuller's earth which has been used as a filter for purifying rosin is washed with a soln. of a rosin solvent such as petroleum naphtha and an org. revivifying liquid such as acetone having a high miscibility with the rosin solvent em-

ployed and at least moderate miscibility with water at the temp. of the process (which may be about 65°). Mention is made of various other solvents which may be used.

Removing water from fuller's earth such as that used for purifying rosin. ROBERT C. PALMER and JOHN L. BURDA. U. S. 1,794,538, March 3. The material is treated with a substantially anhyd. liquid immiscible with water such as petroleum naphtha at a temp. (suitably about 130–150°) above the normal initial b. p. of the liquid and under pressure, and the pressure is then reduced to vaporize part of the anhyd. liquid together with the water contained in the earth.

Casings of weighing apparatus formed of resinous material. C. F. M. VAN BERKEL. Brit. 338,424, Jan. 11, 1930. Casings of weighing app. are formed wholly or in part of molded natural or synthetic resin compn. which may comprise a filling of wood flour, asbestos or linen or other fabric. Various details of manuf. and construction are described.

Refining wood-resin. WILLI SCHULTZE (to A. Schultze & Co.). U. S. 1,793,967, Feb. 24. Resin obtained from dead trees is distd. in a high vacuum (of 8 mm. Hg or less) in the absence of foreign gases.

Modifying the properties of resins. L. AUER. Brit. 337,733, April 24, 1929. In a process such as is described in Brit. 321,724 (*C. A.* **24**, 2904) for modifying the phys. properties of resins contg. high-mol. org. acids, such as colophony or ester gum, the resins are heated under atm. or higher pressure with org. compds. of the O acids of S or their Cl derivs. such as aromatic sulfonic acids or chlorides. The material such as colophony or ester gum may, *e. g.*, be heated at 280–300° in an open vessel with *p*-toluenesulfonyl chloride, 2,5-dichlorobenzenesulfonic acid, β-naphthol-3,6,8-trisulfonic acid or sulfosalicylic acid. The products are either viscous oils or are brittle solids and may be used in *varnishes*. They may be subjected to a supplementary gas treatment or to irradiation. Brit. 337,734 relates to the modification of the phys. properties of fats, fatty oils or fatty acids by heating and dispersing in them modified isocolloids such as those prepd. by heating with amines (Brit. 337,732, following abstr.) or with compds. comprising an org. residue united to an inorg. acidic residue (such as benzenesulfonic acid) as described in Brit. 321,724 (*C. A.* **24**, 2904) or with water-insol. compds. as described in Brit. 321,725 (*C. A.* **24**, 2904), or by treating an aq. soln. of the salts of amines such as benzidine or bianisidine with a soap soln. of high-mol. org. acids. The products may be irradiated with ultra-violet or x-rays, treated with gases such as SO_2 or N, and may be vulcanized; they are suitable for *varnish* or *rubber-substitute manuf.*

Modifying isocolloids for varnish or rubber-substitute manufacture, etc. L. AUER. Brit. 337,732, April 24, 1929. Materials such as linseed or China wood oil or their fatty acids are heated to above 250° (or thickened oils or tung oil to above 200°) with 2–10% of a primary aromatic diamine or a monoamine of high mol. wt. or both, such as *m*-phenylenediamine, *p*-tolylenediamine, β-naphthylamine or *p,p'*-diamines such as *p,p'*-diaminodiphenylamine or *p,p'*-diaminodiphenylurea. Various other substances may be added and the products may be vulcanized with or without use of an accelerator or activator. Cf. *C. A.* **24**, 2904.

Modifying natural and artificial resins. L. AUER. Brit. 337,750, April 24, 1929. Various materials such as colophony or ester gum are heated under less than atm. pressure with metal-free inorg. S compds. such as S chloride, chlorosulfonic acid, H_2SO_4, or sulfuryl or thionyl chloride (suitably at a temp. of about 290–300°). The products thus formed are brown viscous oils or semi-solids suitable for use in varnishes and may be irradiated with ultra-violet or x-rays or mixed with ketones, phenols, etc. Cf. *C. A.* **24**, 2904.

Synthetic resin from xylenols and furfural. EMIL E. NOVOTNY (to John S. Stokes). U. S. 1,793,715, Feb. 24. In making a potentially reactive resinous product, a mixt. of the ingredients is heated to above 100° and the water of soln. and of reaction is removed substantially as fast as it is vaporized while the reactive ingredients are returned to the zone of reaction, and a methylene-contg. hardening agent such as formaldehyde is combined with the reaction product. Cf. *C. A.* **24**, 5173.

Synthetic resins. CARLETON ELLIS (to Ellis-Foster Co.). U. S. 1,793,310, Feb. 17. A chlorination product of toluene, chlorinated in the side chain and contg. benzotrichloride is caused to react on a phenol in the presence of a chloride of Fe or Al to produce a resinous product, and the latter is acted upon with about 10% of CH_2O. U. S. 1,793,311 relates to products similarly formed with the further addition of $(CH_2)_6N_4$, and U. S. 1,793,312 also relates to details of procedure of processes of the same general character.

Synthetic resins. BRITISH CELANESE, LTD. Brit. 338,002, Nov. 17, 1928. A toluenesulfonamide-aldehyde condensation product is further condensed with a toluene-

sulfonamide, and an addn. of 5–10% urea may be made to the initial materials, and the reaction may be effected in the presence of a catalyst of acid or alk. character or in the absence of a catalyst. The products are suitable for use in lacquers, plastic compns., etc., together with cellulose derivs., other synthetic resins, natural resins, solvents, plastifiers, modifiers, etc., various details and examples being given both of the prepn. and use of the products. Cf. *C. A.* **24**, 2317.

Synthetic resins. BRITISH CELANESE, LTD. Brit. 338,024, Dec. 5, 1928. Resinous products prepd. by condensing a toluenesulfonamide-aldehyde condensation product with a toluenesulfonamide, as described in Brit. 338,002 (preceding abstr.) are modified by further condensing with an aldehyde; *e. g.*, a benzene-insol. product formed as described in Brit. 338,002 may be heated with formaldehyde soln. under reflux at 120–150° to form a non-resinous product which is converted into a benzene-sol. resin by heating at 130–150° in an open vessel.

Synthetic resins. WILFRED S. ROTHERA, STANLEY BLYTHEN and HENRY R. GILLESPIE. Ger. 517,251, Feb. 16, 1926. Hydrophobe resins are prepd. by warming urea or a urea deriv. with an aldehyde, particularly CH_2O, for a short time, treating the primary condensation product so obtained with an org. compd. capable of condensing with the aldehyde in an acid medium, *e. g.*, PhOH or thiourea, and then heating the mixt. in the presence of free H ions until the resin ppts. from the mixt. on cooling. The mixt. may be neutralized or rendered feebly alk. before cooling. Examples are given.

Synthetic resins. I. G. FARBENIND. A.-G. Brit. 338,109, May 9, 1929. Cyclic hydrocarbons contg. at least one aromatic nucleus but having no olefinic side chains, such as benzene, naphthalene or tetrahydronaphthalene, or their alkylated, halogenated, nitrated, alkloxylated or carboxylic ester derivs., are condensed with diolefins such as 1,3-butadiene, isoprene or 2,3-dimethyl-1,3-butadiene, in the presence of anhyd. inorg. halides which evolve heat on contact with water such as $AlCl_3$, $ZnCl_2$, $FeCl_3$, B chloride or B fluoride, or of "ansolvo" acids derived from such halides, such as complex compds. of the halides of Zn, Ca or Mg with HOAc. Products are obtained suitable for use in lacquers, etc., and several examples are given.

Synthetic resins. I. G. FARBENIND. A.-G. (Friedrich Frick, inventor). Ger. 517,430, Dec. 29, 1928. Resins are prepd. by condensing urea with CH_2O in the presence of aryl ethers of glycols or polyglycols, or lower fatty acid esters of such ethers. About 0.5 mol. of glycol deriv. may be taken for each mol. of urea. Examples are given. Cf. *C. A.* **25**, 835

Synthetic resins. I. G. FARBENIND. A.-G. (Leo Rosenthal, inventor). Ger. 517,477, May 1, 1928. Resins are prepd. by treating crude solvent naphtha, alone or contg. phenols or naphthols, with compds. of BF_3 and fatty acids. The reaction may be effected by gradually adding about 3% of a BF_3-fatty acid compd. to crude solvent naphtha while stirring and preventing rise of temp. above 70°. The products are colorless or nearly so, and are *useful as varnish bases.* Examples are given.

Apparatus for cutting thin sheets from a heated block of fully hardened artificial resin. HEROLD A.-G. Brit. 337,530, Sept. 13, 1929. Structural features.

Urea-formaldehyde resins. TOLEDO SCALE MFG. CO. Brit. 337,357, April 27, 1929. Urea and CH_2O are caused to react in aq. soln. to form an initial condensation product, the soln. is concd., a condensation product of a "polybasic" acid and a polyhydric alc. is then added and the soln. is further concd. In the initial condensation, the p_H may be adjusted to from 5 to 6 by adding triethanolamine, and after such condensation the p_H may be increased to 7 or 8. Sufficient of the "polybasic acid"-polyhydric alc. condensation product may be added to lower the p_H to 3.5 to 5.0 and the mixt. may be dried by heating *in vacuo* and may be molded under pressure and cured by heating. Thiourea may be substituted for part of the urea. Cf. *C. A.* **24**, 6041.

Linoxyn or similar material. VICTOR SCHOLZ (to Atlas Ago Chemische Fabrik). U. S. 1,794,325, Feb. 24. Oil such as linseed oil is preliminarily converted into a jelly by heating and blowing with air and is then subjected to a kneading process to give the product a fine crumby, flaky, yellowish opaque character. Cf. *C. A.* **24**, 2316.

Decorating linoleum and similar materials. H. W. PRENTIS (to Armstrong Cork Co.). Brit. 338,205, Oct. 9, 1928. Various mech. features of operation are described.

Forming color patterns on linoleum, felt, oil cloth, etc. J. C. MCCARTHY (to Armstrong Cork Co.). Brit. 337,924, Nov. 21, 1928. Various details are given of procedure for successive color applications. Cf. *C. A.* **24**, 2623.

Floor covering. JULIAN T. BALDWIN (to Sandura Co.). U. S. 1,793,666, Feb. 24. A thin sheet material such as paper is placed on a supporting base such as a linoleum

or felt base with an intervening cementing material comprising a resin such as rosin, shellac or ester gum, a plasticizer for the resin such as diethyl phthalate and a "modifier" such as montan wax, rubber or oil and the product is provided with a decorative coat such as a pigmented resin compn. and an overlying transparent wear-resisting coating such as a shellac varnish contg. a plasticizer. U. S. 1,793,667 relates to floor covering material prepd. by mixing body ingredients such as cork, wood flour, starch or rubber with a binder such as a resin and plasticizer and affixing the resulting mixt. under pressure to a fibrous support such as textile fabric.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

A new method for determining iron in fats and soaps. O. HAGEN. *Seifensieder-Ztg.* **58**, 110–2(1931).—H. dets. Fe in oils by carefully ashing 10 g. and detg. Fe in the HCl soln. of the ash colorimetrically with standard Fe soln. and KCNS. The following results are tabulated: colorless coconut oil 0.4–0.9, I A lard 0.6, II A lard 27.0, 1st pressing castor oil 0.9, tallow 4.5–36.0, coconut oil fatty acids 20.7 mg. Fe per kg. of oil. Soaps are ashed in successive portions; a total of 5 g. is used and combustion is aided with a few crystals of NH_4NO_3. The titration with KCNS gave for soaps a content of 2.3–25.2 mg. Fe per kg. of soap. In a series of expts. for development of brown spots, the unchanged soaps contained 1.4–1.8 and the discolored soaps up to 9.0 mg. Fe per kg. P. ESCHER

Wool fat. P. MARTELL. *Pharm. Presse, Wiss.-Prakt. Heft* **1931**, 17–8.—A description of the secretion of wool fat and of its phys. and chem. properties in connection with the usual procedures followed in the production of the crude and refined brands. W. O. E.

Wool fat, its properties and composition. G. SALOMONE. *Boll. laniera* **44**, 199–201(1930).—The properties and compn. of wool fat depend greatly on the way it is extd. The wax extd. with petr. ether has a thicker consistency and is richer in hydroxy acids than that extd. with trichloroethylene. It is brown or brown-yellow, has no disagreeable odor, is little sol. in 95° alc., much more in ether, in benzine, in chloroform, trichloroethylene, CS_2, and is dextrorotatory. It has d_{15} 0.941–0.945, m. 36–42°, sapon. no. 98–115, I no. 17–29, unsaponifiable 30–52%, fatty acids m. 42°, mol. wt. of acids 327.3. The fat extd. with petr. ether or acetone has little acidity, while that obtained from scouring baths has 20–25% of free fatty acids calcd. as oleic acid. Wool fat is difficultly sapond.; it contains lactones that are transformed gradually by the alkali into acids and their salts. There is a little myristic acid and a large amt. of palmitic, stearic, carnaubic and cerotic acids. Small quantities of cetyl, carnaubyl and ceryl alcs. are present with cholesterol, isocholesterol and oxycholesterol, in a free state in limited amount, and for the greater part esterified with the fatty acids. Such alcs. represent the unsaponifiable portion that can reach 50% of wool fat. The esters predominating in wool fat are principally palmitate, stearate and cerotate of cholesterol and isocholesterol. The identification of wool fat is based on the presence of cholesterol. Impure wool fat, if exposed for some time to air, becomes brown, and acquires a less disagreeable odor, a greater consistency, a higher refractive index, a lower I no., a less complete soly. in petr. ether and a higher mol. wt. by the decompn. of the cholesterol esters that are first hydrolyzed and then oxidized. R. SANSONE

Freezing-point method for the examination of cacao butter. A. G. AVENT. *Analyst* **56**, 180(1931).—In the paper published on the classification of chocolate fats by the f.-p. method (*C. A.* **24**, 4946) mention should have been made of the assistance obtained from H. R. Jensen in devising the standard solidification test. W. T. H.

Extracted cacao butter—imitation or adulterated. W. NORMANN. *Allgem. Öl Fett. Ztg.* **27**, 259–61(1930).—The inconsistency of German rulings on the subject of extd. edible fats is discussed. W. F. BOLLENS

Measurement of rate of formation of oxidative decomposition products in fats and oils. D. P. GRETTIE AND R. C. NEWTON. *Ind. Eng. Chem., Anal. Ed.* **3**, 171–3(1931).—The method used is a modification of the methods of Bailey and Issoglio. The measurement of the volatile products is taken as a measurement of the degree of spoilage of the fat, and is performed by titrating against acid $KMnO_4$; the products carried away in a given time by a const. stream of air pass over the fat which is dispersed on filter paper and maintained at a specified elevated temp. The stream of air is drawn over the fat and then through a standard soln. of acid $KMnO_4$ maintained at 25°. This

soln. is then titrated against oxalic acid to det. how much was used by the decompn. products condensed in it. E. SCHERUBEL

Causes of deterioration of fats and oils. W. L. DAVIES. *Oil and Fat. Ind.* 7, 427–31, 453–7(1930).—The 2 main causes of deterioration are oxidation and the agency of microörganisms. O absorption is not rapid until after the induction period has been overcome. This means the time required by the system to undergo activation. The conditions likely to catalyze the subsequent oxidation of fats have also the effect of shortening the induction period, *e. g.*, heat, light, acidity, other impurities and metallic catalysts. Lipoids in fats are oxidized first; thus in butter the fishy flavor is due to oxidation of lecithin forming trimethylamine. Foots which contain lipase and protein decompn. products also shorten the induction period. The tests used for following the course of oxidation such as the Kreis test and the extn. of the oxidizability values of the steam-volatile or water-sol. products of oxidation have been found valueless in detecting incipient deterioration. When bacteria are present in fat no autocatalytic oxidation occurs as the organisms use all available O in the fat. Molds cause more deterioration in fats than bacteria. They are of 2 classes: those which preserve the solid consistency of fat and those which have strong lipolytic properties and liberate fatty acid. Very little is known of the effect of yeasts on fat. E. SCHERUBEL

Determination of rancidity in oils and fats. ALAN TAFFEL AND CECIL REVIS. *J. Soc. Chem. Ind.* 50, 87–91T(1931).—On account of emulsification caused by ether in the Kreis reagent and the presence of peroxides which tend to oxidize phloroglucinol, the Kreis test was modified by substituting alc. for ether and using 10 drops of a 5% soln. of phloroglucinol in alc Oils which have been air-blown or have become rancid at moderate temp. contain peroxides which are reduced by HI and oils becoming rancid around 120° contain more peroxides together with other forms of combined O which offer more resistance to reduction by HI. Oils air-blown at 170° contain only difficultly reducible peroxides. The amts. of each type of oxide present in an oil can be detd. For oils becoming rancid at moderate temp., add 10 g. of oil to 40 cc. glacial AcOH and then 2 cc. of 50% KI soln. Shake the mixt. for 2 min., hold for 2 min. and again shake for 2 min. and then pour into 100 cc. H_2O, rinse with 20 cc. and titrate with 0.1 *N* $Na_2S_2O_3$ and starch. Two g. of BaI_2 may be used instead of the KI soln. For oils which have become rancid by exposure to air at high temp. the proportions of the reagents must be found by expts. Ten to 20 g. of BaI_2 and 100 cc. of AcOH are suitable for 1.25 to 2.5 g. of oil. For the samples examd. the Kreis reaction and the I or peroxide figure showed a close correlation, a strong reaction of the former accompanying a high peroxide figure. While the peroxide methods have not stood the test of long experience they are of apparently general application to all types of rancidity. Definite and reproducible figures are obtained by the methods which distinguish between oxidation in ordinary rancid oils and that which occurs in oils blown at high temps. E. S.

Three new oils. ERICH STOCK. *Farben-Ztg.* 36, 830(1931).—The analytical consts. of 3 new oils were:

	Moquilia tomentosa Benth.	*Oenocarpus*	*Udilo*
sp. gr.	0.9864 (at 16°)	0.9244 (at 15°)	0.9241 (at 15°)
solidification pt.	—14 5°	7.5°	7.9°
n	1.4919 (at 30°)	1.4700 (at 15°)	1.4699 (at 15°)
sapon. no.	196	190	198.9
acid no.	18.8	1.38	66.9
I no. (Wijs)	81.5	80.6	98.8
unsaponifiable %	7.5	0.84	....
resins	..	...	19.4%

G. G. SWARD

Some titer points of mixed fatty acids. I. Mixtures of commercial oils, fats and fatty acids. GEORGE W. JENNINGS. *Ind. Eng. Chem.* 23, 413–5(1931).—Mixed fatty acids of tallow, corn, olive, coconut and cottonseed oils, garbage, grease and red oil were prepd. and mixed with each other in the desired proportion just before detn. of the titer. The results are reported in the form of curves, plotted with the titer points as ordinates and the % compn. of the mixed fatty acids as abscissas. The work is to continue in order to explain the cause of the apparently erratic results obtained in some cases. E. SCHERUBEL

Intramolecular rearrangement of the ester of simple unsaturated fatty acids during hydrogenation. A. STEGER AND H. W. SCHEFFERS. *Chem. Umschau Fette, Oele, Wachse Harze* 38, 45–53(1931).—S. and S. used specially prepd. pure ethyl, glycol and glycerol esters, etc., for a partial and complete hydrogenation with Ni on kieselguhr—

reduced at fixed temps. and with Pd on C according to Mannich and Thiele (*C. A.* **10**, 2158). They examd. the influence of Ni reduction temps., of the hardening temps. and of the amt. of catalyst upon the quality of the product. The results of the detns. of the I no. of the liquid and solid acids, % solid acids and % linolic acid are tabulated and plotted in graphs. Results: Solid isoöleic acid is formed soon after hydrogenation; higher temp. increases it and a max. is reached at 50–60 I no.; linolic acid disappears rapidly and becomes oleic acid, especially at higher temps.; no stearic acid is formed until only a few percentages of linolic acid remain. Oleic esters have their oleic acid in part converted into isoöleic acid which reaches a max. and then diminishes, disappearing entirely around I no. 20. Et esters form more iso-acid than glycerol esters. Solid elaidic ester forms liquid oleic acid, more of it with Et ester than with glycerides. Changes in the reduction temp. of Ni are not reflected in the phys. properties of the product; an increase in the amt. of catalyst increases the isoöleic acid but slightly. A Pd catalyst forms more iso-acid than Ni; but the type of carrier (kieselguhr and C) does not influence the results. P. ESCHER

Detection of sesame oil in solid mixtures of fats. R. LUCENTINI. *Ind. olii minerali e grassi* **10**, 156–7(1930).—If less than 0.5% of sesame oil is present ext. 50 g. of the melted fat for 2 hrs. with 100 cc. 95° alc., using a Marino extractor, cool to ppt. the excess of dissolved fat, filter and evap. off the alc. on the water bath. The residue contains, with a little fat, the greater part of the phenolic substance that produces the color reaction for sesame oil. After cooling, dissolve the residue in 5 cc. of petr. ether, bring it into a test tube contg. 2 drops of a furfurole soln. in alc., add 5 cc. of concd. HCl and agitate several times softly. In the presence, even of very small quantities of sesame oil, a pink-red color is produced. R. SANSONE

Vitamins and palm oil in margarine. ALBERT K. EPSTEIN. *Oil and Fat Ind.* **8**, 107, 109(1931).—Tests made on samples of palm oil made from selected raw material and which were refined and deodorized by careful methods were found to respond to the Drummond color test for vitamin A equiv. to about 60 units per g. This is a higher test than that given by the av. butter. E. SCHERUBEL

Present state of the olive-oil industry in Italy. HUMBERTO MORINI. *Quim. e ind.* **7**, 232–5(1930). S. L. B. ETHERTON

Analysis of olive oil in Wood's light. G. LOEW. *Ind. olii minerali e grassi* **10**, 140–2(1930); cf. *C. A.* **24**, 1532.—Tests showed that the olive fluorescence of olive oil is due principally to the presence of vitamin C or to a substance that accompanies vitamin C. R. SANSONE

Utilization of the aqueous extracts from olives. RICCARDO CIUSA, ANGELO MANGINI AND DOMENICO MASSIMEO. *Industria Chimica* **5**, 1461–4(1930).—The aq. ext. obtained during the manuf. of olive oil, previously rejected, has been found to undergo spontaneous fermentation, a max. of 3% EtOH being obtainable. In addn. ½% of oil can be recovered by centrifuging, as well as 2% of KCl. A. W. CONTIERI

The processing of the fish oils. G. HINARD. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* **8**, 161–7(1930).—The properties and uses of fish oils and of products obtained from fish oils are discussed and the methods involved in the prepn. of the products are described. G. SCHWOCH

The behavior of bleaching powders in acid oils and attempts at removing free acid by distillation. LEV PICK. *Allgem. Öl- Fettztg.* **27**, 291–4(1930).—Bleaching earths and carbons, when mixed at 105° with peanut oil or coconut oil, contg. free fatty acids, were found partially to remove the free acidity. This was found to be true for acid earths, as well as for neutral earths, when amts. of 10–50% were used. This removal of free acid is thought to be due to the adsorption of the free carboxyl groups to the surfaces of the bleaching powder. This interferes with the adsorption of pigments, and thus accounts for the lower bleaching power of earths and C on acid oils. Attempts to remove the free acidity from peanut oil by steam distn. at atm. pressure were only partially successful. The best results were obtained at 287°, the free acidity being reduced from 3.5 to 2.0%. During the distn. 2.7% of fatty acids was distd. off, showing that hydrolysis had taken place. When this procedure was used on coconut oil, the free acidity was reduced from 2.2 to 0.2%. The distn. temp. was 305°. When 3% of coconut oil was added to peanut oil (free acid 4.5%) and subjected to the above process, at 300°, the free acid was reduced to 0.4%. This difference in behavior of the 2 oils is said to be that, at temps. of 280° to 300°, the higher free acids replace the lower acids of coconut oil, which at this temp. are readily distd. leaving a practically neutral oil. Attempts were also made to remove the free acid by distn. with a volatile solvent. An app. is described in which the oil dissolved in benzene (2:1) is subjected to a continuous distn. under a reduced pressure of about 100 mm. Hg. The benzene soln. is

drawn through a long Al tube submerged in an oil bath at 300°, and thence into a flask submerged in an oil bath at 250°. The neutral oil collects in this flask, while the fatty acid and benzene vapors are carried through a condenser into a receiver. This procedure reduced the free acid of peanut oil from 4.0 to 0.4%, and that of coconut oil from 1.4 to 0.1%. In another sample of coconut oil the free acid was reduced from 13.6 to 0.7%. W. F. BOLLENS

Substitution of steam for carbon dioxide in the hydrogenation of oils. V. YASHCHENKO. *Masloboino Zhirovoe Delo* **1929**, No. 5, 23–4; *Chimie & industrie* **23**, 427–8.—Before removal of the catalyst after hydrogenation CO_2 is passed through the hydrogenation vessel. Passing steam at about 120–40° (to prevent condensation) was found equally satisfactory. A. PAPINEAU-COUTURE

Preparation of nickel catalyst for the hydrogenation of oils. A. BAG. *Masloboino Zhirovoe Delo* **1929**, No. 5, 32–4; *Chimie & industrie* **23**, 428.—In the regeneration of Ni catalyst, the Fe being present in the Fe^{++} state ppts. as $FeCO_3$ along with the $NiCO_3$ instead of with the Al and Zn. This is overcome by aerating the soln. before pptn. to convert Fe^{++} into Fe^{+++}. A more active catalyst is obtained by pptg. the Ni by adding the $NiSO_4$ soln. to the mixt. of kieselguhr and Na_2CO_3 soln., instead of *vice versa*. A. PAPINEAU-COUTURE

The effect of supports on the catalytic activity of nickel. CHARLES R. GLASS AND LOUIS KAHLENBERG. *Trans. Elektrochem. Soc.* **59**, preprint(1931).—Those support materials which inhibit the catalytic activity of Pt and Pd have been found to effect Ni similarly. The behavior of the supports with relation to the hydrogenation of cottonseed oil by Ni can be classified as follows: Reducible heavy metal oxides completely inhibit the activity of Ni. The salts of those metals that decompose on heating in a stream of H completely inhibit activity. Substances with corrosive properties retard but do not completely inhibit activity. The salts in every case have been found to yield more active supports than the corresponding oxides. The more inert the support becomes toward Ni the greater is its tendency to enhance activity. The less inert the support becomes toward Ni, the greater is its tendency to retard activity. The oxides of Si, Al, Cr, Mn, Ti, Ce, U and Mg and the phosphates and borates of Al, Cr, Mn, Ce, U, Mg, Ca, Sr, Ba and Li proved very beneficial as supports for Ni in hydrogenation. C. G. F.

The bleaching of waxes. J. DAVIDSOHN. *Allgem. Öl- Fettztg.* **27**, 261–2, 286–7, 312–3(1930).—A review. W. F. BOLLENS

Sodium chloride determination in soaps. STEINCHEN. *Seifensieder-Ztg.* **58**, 112–3 (1931).—S. combines the NaCl detn. with that of the total alkali and the fatty acids, using Volhard's KCNS method for the NaCl detn.: Decompose 5 g. with known HNO_3, shake out with ether, wash the ether soln. for fatty acid detn. To the HNO_3 soln. add 5 cc. ether per 100 cc. soln., shake out, add 5–10 cc. 0.1 *N* $AgNO_3$, shake well and set aside for 5 min. in the dark; add Fe indicator in HNO_3 soln. and titrate back with KCNS to a light rose tint. P. ESCHER

Properties of soap solutions. I. Estimation of detergent capacity. B. TYUTYUNNIKOV. *Allgem. Öl- Fettztg.* **27**, 241–3(1930).—The ideal way of expressing detergent capacity would be to express it in terms of the energy, which a known soln. of known concn. and temp. exercises toward the overcoming of the attaction between the substrate and soil, and toward the suspension of the soil in the soln. This energy would be measured by phys. and colloidal chem. methods, rather than by the highly standardized exptl. washing tests. **II. The influence of saponin on soap solutions.** B. TYUTYUNNIKOV, N. KASSVANOVA AND R. GVIRZMAN. *Ibid* 273–6, 294–8(1930).—The influence of the addn. of successive portions of saponin soln. to soap solns. is divided into 3 stages. In the 1st stage the lathering power is reduced until it is 0. During the 2nd stage the lathering power remains at 0 while during the 3rd stage lather is again produced. Curves showing the influence of addns. of saponin on the lathering properties of Na soaps of various fatty acids and of rosin are given. Tables are also given showing the influence of addns. of saponin to these soaps on the lather vol. (cf. *C. A.* **24**, 3668), the property of carrying pptd. MnO_2 through a filter, and the surface tension. It is supposed that the saponin is adsorbed by the soap, and that the adsorbing power of the soap is not completely satisfied until the beginning of the 3rd stage. This may be numerically expressed by the amt. of saponin required just to bring forth a lather after having destroyed it, expressed in multiples of the wt. of soap present in the soap soln. The no. is called the saponin no. Saponins of different origins were found to give somewhat different results, and as yet no method for the evaluation of the various saponins has been developed. W. F. BOLLENS

Evaluation of detergency. JAMES G. VAIL. *Soap* **7**, No. 3, 29–30(1931).—The

trend in soiling tests has been in favor of simple pigments, carbon black and umber being preferred. Two methods of applying pigments in water give fairly even colors. In one, 5 g. of umber in 100 ml. of water is used with 5 × 12 in. of cloth which is passed through a clothes wringer and the treatment repeated until the cloth color is const. The second method involves the use of the Launderometer, a machine with a round-bottom metal tank supported in an open frame and having a shaft bearing 16 threaded posts. By means of clips and wing nuts 20 jars may be attached. A motor drives the shaft at 40 r. p. m. Heat is applied by a gas burner underneath. A cloth bag contg. 50 Monel metal balls is rotated for 1 hr. at 60° in a suspension of 1 g. of umber in 100 ml. of water. This machine is also used for the washing tests. For judging results a color chart was devised but results did not agree and another plan was to print the color in stripes across the cloth. Washing was to be continued until the marks were invisible but it was difficult to judge when they disappeared. At present no procedure has been adopted. E. SCHERUBEL

[Fatty acids of] the resins of jack pine (PHILLIPS) **23.** The oxidation of the fat used in oiled wool (SALOMONE) **25.** Floating factories [for whale oil] (HAUPTVOGEL) **15.** Calculating viscosity and flash point in compounded oils (KADMER) **2.** Report of the oil and fat commission (AUERBACH) **29.** The higher alcohols of the paraffin series [as waxes] (SCHRAUTH) **10.** Wax emulsions [for soaps] (Brit. pat. 338,176) **18.** Solvents for fats and waxes (Ger. pat. 517,097) **13.** Thickening oils (Brit. pat. 337,639) **22.** Method and plant for separating waxy and fatty substances from oils (Ger. pat. 517,198) **22.** Rotary impeller agitating device and filter for treating oils (U. S. pat. 1,794,916) **1.** Apparatus for extractions with liquid solvents (U. Fat separators. WILHELM STEINMANN Swiss 142,451, Nov. 2, 1929. A fat separator for a plant for working up animal waste, carcasses, etc., is described.

Extracting oils and grease with solvents. IMPERIAL CHEMICAL INDUSTRIES, LTD., and F. E. ROGERS. Brit. 337,770, Aug. 1, 1929. Various details of app. are described for use in a process such as described in Brit. 278,891 (*C. A.* **22**, 2851). A condenser and the means for heating the app. are interconnected so that the cooling of the condenser ceases when the heat is shut off.

Organic peroxide for oxidizing or decoloring. HENRY B. FABER (to S. G. Turnbull). U. S. 1,793,917, Feb. 24. Substitution of O for Cl in material comprising an aliphatic dicarboxylic acid chloride and an aromatic monocarboxylic acid chloride (such as the reaction products from heating fumaric acid with benzotrichloride at 140–170°) is effected by treatment with H_2O_2 in the presence of an alk. substance such as Na_2CO_3. The product may be used for oxidizing or decolorizing oils, cereals, cereal products, etc.

Leaching materials such as in extracting oil from seeds. JESSE M. COAHRAN. U. S. 1,793,465, Feb. 24. Various details of app. and procedure for countercurrent extn. are described.

Obtaining oil, protein material, starch and cellulose from seeds. LOUIS F. DAVID and GEORGES FELIZAT. U. S. 1,794,105, Feb. 24. Seeds are crushed and the crushed mass is mixed with a slightly alk. aq. soln. such as Na_2CO_3 to dissolve protein material, swell the cellulose and suspend the starch and oils (the latter being in emulsion); the cellulose is sepd. by screening, the screened liquid is centrifuged at slow speed to sep. suspended starch, and the liquid is then centrifuged at higher speed to break the emulsion and sep. the oil; the liquid from the second centrifuging is treated with acid to ppt. protein material.

Apparatus for separating solvent from extracted seeds. KARL LÖFFL. Ger. 514,915, Feb. 6, 1929. The greater part of the solvent is recovered by blowing non-condensable gas through the seeds, and the remainder by squirting the seed through a nozzle into a chamber.

Scouring composition. W. J. A. HUYZER. Brit. 337,355, July 26, 1929. Soap powder is mixed with 1–3 times its quantity of natural magnesite ground to approx. 50 mesh per linear in.

Dry soap. ALBERT RUF. Swiss 142,452, May 13, 1929. A good ordinary soap is dissolved in boiling water. Calcined soda and a water-fixing stabilizing agent are added. The whole is reboiled and spirit added during violent agitation. On cooling, the whole is worked up to a creamy mass. In the example palm-olive soap forms the starting material.

Apparatus for molding soap. L. H. NELLES. Brit. 337,430, May 2, 1929. Structural features.

Cold press for soap, with heat-absorbing plates. AUGUST JACOBI A.-G. Ger. 514,520, Dec. 20, 1929.

28—SUGAR, STARCH AND GUMS

J. K. DALE

A hundred years ago. X. E. O. v. LIPPMANN. *Deut. Zuckerind.* **56**, 18–9(1931); cf. *C. A.* **24**, 1536.—A history of beet sugar. J. F. LEETE

Cuba's five-year plan. EARL L. SYMES. *Intern. Sugar J.* **32**, 612–4(1930).—A description of the operation of the governmental control method for sugar production in Cuba which became effective Nov. 15, 1930. W. L. OWEN

Technical notes from Usina Cucau Pernambuco. N. E. LAMONT. *Intern. Sugar J.* **32**, 629–31(1930).—The use of "Sumaphos" in clarification applied at the rate of 200 g. per ton of cane at the liming and sulfuring tanks results in an improved decantation and an increased yield of sugar, while the massecuites are freer working and the washed sugars are much more easily filtered. Expts. made on the purging of second massecuites with warm dil. exhausted molasses showed that the purity of the resultant molasses was on an av. 1% lower than without this aid and the actual time gained in curing each charge was reduced 20%. Expts. on the influence of p_H on alc. recovery showed that the closer the initial p_H to that of the final fermented wash, the higher is the efficiency of yield. An increase of 18% in yield was obtained by introducing the fresh wort on a footing of sour wash. W. L. OWEN

Factory results in Java during the last seven years. R. J. PRINSEN-GEERLIGS. *Intern. Sugar J.* **32**, 631(1930). W. L. OWEN

Dilution in relation to comparative purities. NOEL DEERR. *Intern. Sugar J.* **32**, 616–7(1930).—D. discusses Hill's article (cf. *C. A.* **24**, 6023) and replies to the exception taken by the latter to the statement that *"to be strictly comparable, gravity solids detns. should be made in solns. of the same nonsugar concn."* Taking the formula sugar recovered $S(J - M)/J(S - M)$, where S, J and M are the purities of the sugar recovered, the original impure material, and the residue or molasses, resp., D demonstrates that an accurate Brix or gravity solids balance can also be made where nonsugars are detd. in equal concns. The identity of the values obtained from the use of absolute and gravity purities shows what is meant by the word "comparable" in the official Direction of the Hawaiian Sugar Technologists. W. L. OWEN

Cylindrical or centrifugal pumps (in the sugar industry)? V. SÁZAVSKÝ. *Z. Zuckerind. Čechoslovak. Rep.* **55**, 127–8(1930).—A discussion. S. states that centrifugal pumps are suitable even for mud liquors. J. F. LEETE

An improvement in the testing of press mud for sugar. F. BRUCKNER AND TH. BREITHAUPT. *Centr. Zuckerind.* **38**, 1359(1930).—The authors find that foaming and dark-colored filtrates are avoided by substituting a soln. contg. 8% NH_4NO_3 and 2% $Al(NO_3)_3$ for the 10% NH_4NO_3 soln. in the method of the Institut für Zucker-Industrie. Numerous expts. indicate that no errors are introduced by the change. J. F. L.

The calculation of the amount of massecuite in a white sugar factory. E. DEHN. *Deut. Zuckerind.* **55**, 1031–2, 1080–1(1930).—A math. discussion. J. F. LEETE

Charring of sugar in centrifuging. W. C. BEDDING. *Arch. Suikerind.* **38**, 256 (1930).—Sugar which was gray was found under the microscope to be permeated with particles of C, because of the fact that it had been washed with superheated steam which had been produced from boiler water contg. sugar. B. C. A.

Precipitation of lime by sulfurous acid in sugar solutions. EMILE SAILLARD. *Compt. rend.* **192**, 178–80(1931).—This study was undertaken to decide whether SO_2 added to limed juices combines first with the lime, with the alkalies, or with both at the same time. Solns. contg. 10 and 20%, resp., of sugar were prepd. One g. CaO and increasing quantities of NaOH were added to each. Then SO_2, amounting to less than its CaO equiv., was passed into the solns. The alky. and the % SO_2 in the filtrates were detd. It was found that the SO_2 combines with both the CaO and the NaOH. As the quantity of NaOH increases, more SO_2 is taken up by it. At equal alky., more SO_2 combines with the CaO if the soln. contains a large % of sucrose. F. W. ZERBAN

The use of the refractometer in cane-seedling selection work. N. CRAIG. *Intern. Sugar J.* **33**, 14–18(1931).—The refractometer can be used to advantage in cane-seedling work, the results obtained being very reliable. The method of sampling is rapid, re-

liable and easy of application. Whenever possible it is advantageous to take 6 borings from each stool, although the analysis of 3 borings is sufficient to give a fairly good indication of the sugar-producing capacity of a cane seedling. The final choice of a seedling should be decided by the weights of the cane in the stool, and the richness in sucrose, and of these two the latter, which shows no correlation with the wt., is the more difficult to det. W. L. OWEN

Recent investigations into sugar-beet problems. I. Storage of sugar beet. G. R. CLARKE, L. F. NEWMAN AND A. W. LING. *J. Ministry Agr.* **36**, 950–60(1930); cf. *C. A.* **24**, 2629.—Beets were stored in various types of clamps during one season; in the next season only the mangold type of clamp was used, with free circulation of air. Samples were removed at stated intervals, and the following detns. made: loss in wt., dry substance in pulp, and % sucrose by Sachs-le-Docte method; the latter was checked by other methods. The results are shown in 8 tables. Conclusions: Under adverse climatic conditions beets lose both moisture and dry substance. Beets crowned before storage may seriously deteriorate. Secondary growth may start in imperfectly cut or in uncrowned beets. The net result is a decrease in the com. sugar yield. With normal weather conditions the loss is very small, and in favorable seasons beets can be stored without serious damage. F. W. ZERBAN

Increasing the daily production or lengthening the (beet sugar) campaign. P. HIRSCHFELDER. *Deut. Zuckerind.* **56**, 41-2(1931).—A discussion. H. points out 3 reasons in favor of a longer campaign; the low price of sugar, high interest rates and good storage facilities for beets. **Reply.** E. TROJE. *Ibid* 95–6. J. F. L.

Comparative determination of the marc content of fresh and stored (sugar) beets by the methods of Claassen and of Thielepape and Meier. MATSCHKY. *Centr. Zuckerind.* **38**, 1112(1930).—M. describes and discusses his methods. The exptl. data show agreement within 0.10% by the 2 methods in most cases. The greatest discrepancy found was Claassen 5.31%, T. and M. 4.76%. J. F. LEETE

The determination of the natural alkalinity (in sugar-beet juice): the method of the Institut für Zucker-Industrie or that of Düwell and Solon. K. DOMNING. *Deut. Zuckerind.* **55**, 1054–82(1930).—D. gives comparative results for the 2 methods and concludes that the D. and S. method is sufficiently accurate for factory control when only natural residual alky. and residual lime are to be detd., provided NH_3 is boiled out before carbonation, but recommends an occasional check by the method of the Institut. J. F. LEETE

The sugar losses of beet-sugar manufacture. H. CLAASSEN. *Intern. Sugar J.* **32**, 580–1, 626–9(1930); cf. *C. A.* **24**, 2912.—The total losses in the usual method of working in beet-sugar manuf. amounts to 1.2–1.5% of the roots when all calcns. are carried out by correct methods. The correct estn. of the wt. of roots entering the factory is of prime importance. Through faulty detns. this error may have a value of from ±0.05 to ±0.10. When returning the best wastes (tails) into the process, the quantity of sugar so introduced should be calcd. Because of inadequate sampling too low figures are usually found for the detd. loss, while with proper sampling they amount to from 0.4 to 0.6% of the roots. Undetd. losses, or losses undeterminable according to the usual methods, reach up to 0.75–0.90% of the roots, and are composed of apparent losses due to incorrect tares, increase of polarization of the beet slices through drying, polarization increases from the action of lime, too low results from the sugar content of the scums, sugar losses from decompn., and mech. sugar losses. Hence of the 0.75–0.90% undeterminable losses from 0.3 to 0.4% can be explained, while the remainder cannot be accounted for. W. L OWEN

Action of different decolorizing products in beet-sugar refining. C. GROSSI. *Ind. Saccarif. Ital.* **22**, 489–94(1929).—When decolorizing beet sirups with animal charcoal an excess of alkali is not beneficial, but increases the ash of the sugar. As the absorption of good charcoals is only 0.002%, alky. between 0.01 and 0.015% is a sufficient protection against inversion during a first and second refining. 0.3% CaO does not cause sirups contg. a min. of invert sugar to become strongly colored, even when these are kept for more than 1 hr. at 90°. It often causes a slight ppt. Turbidity takes away a part or all the decolorizing power of the animal C. Only a limited portion of the color is removed by the animal C, an excess causing no further color removal. 0.035% gives good results. There was no improvement when the amt. was doubled The addn. of hyposulfite always gave satisfaction. In reasonable amt., no inversion took place in slightly alk. massecuites. Fifty g. of hyposulfite is effective with 14 tons of first refining massecuites, while 14 tons of 2nd refining massecuites require 100 g. Most of the hyposulfite decoloration resists subsequent oxidation. R. S.

The question of the applicability of the conductimetric method for the official

determination of ash in raw (beet) sugars. J. PUCHERNA. *Z. Zuckerind. cechoslovak. Rep.* **55**, 205–6(1931); cf. *C. A.* **25**, 1406.—A discussion with statistical data. P. recommends the adoption of the conductimetric method. J. F. LEETE

The conductometric ash apparatus (for beet sugar) in the practical field. Q. JEDLIČKA. *Z. Zuckerind. cechoslovak. Rep.* **55**, 227–8(1931).—A discussion with statistics from 3 campaigns. J. prefers this method. J. F. LEETE

Measurement of turbidity with a spectrophotometer, with especial reference to sugarhouse products. R. T. BALCH. *Ind. Eng. Chem., Anal. Ed.* **3**, 124–6(1931).—Previous methods, none of which has come into extended use, are reviewed. The present method is based on a direct spectrophotometric comparison; the transmittancy is detd., with the turbid soln. in one cell, and a filtered portion of the same soln. in the other. Filtration through paper with the aid of a slow filtering type of kieselguhr is satisfactory. Kieselguhr does not cause true adsorption. Solids and semisolid products are dild. to approx. 50 Brix; any similar products to be compared should be dild. always to the same concn. The transmittancy measurements may be made at any convenient wave length, such as 560 mμ, but it was observed that the transmittancies at the red end of the spectrum are higher than those at the blue end. Beer's law does not hold exactly, but the approximation is close enough to permit expression of the turbidity in terms of $-\log t$. Expts. with bentonite suspensions showed that equal turbidity concentrates in a water-white medium and in one colored strongly with caramel give the same transmittancy readings. The results of turbidity measurements on a no. of granulated and raw sugars are given in a table, and it is also shown that the turbidities found are roughly proportional to the % of suspended matter obtained by weighing. F. W. ZERBAN

Working of molasses in the experimental molasses station at the sugar plant in Gniezno. FELIKS POLAK. *Przemysl Chem.* **15**, 37–43(1931).—This work is based chiefly on the sulfite fermentation of molasses. The app. and processes are discussed. The experimentation has reached a semi-plant stage in its development and includes fermentation and distn. of alc. and AcH, oxidation of the aldehyde to HOAc, oxidation of the sulfite to sulfate and distn. and purification of glycerol. A. C. ZACHLIN

Acetone compounds of the sugars and their derivatives (OHLE, LICHTENSTEIN) **10**. Sugar-beet root-rot control (YOUNG) **15**. The use of excess molasses (CLAASSEN) **15**. The use of sugar for motor fuel (ŠANDERA, ZEMAN) **21**. Report of the most important work in the field of pure sugar chemistry published during the first half of the year 1930 (v. LIPPMANN) **10**. 29—LEATHER AND GLUE

ALLEN ROGERS

Bibliography of papers on the physical properties of leather. III. C. H. SPIERS. *J. Intern. Soc. Leather Trades Chem.* **15**, 61–7(1931); cf. *C. A.* **24**, 4951, 5178.—The references are classified under: *gaseous permeability* (13 titles); behavior to *bending* forces (30); *cracking* of grain (46); pipiness, *break* (14); *tinniness* (5); resistance to

tear (13); behavior on *compression* (6); *hardness* (3); *resilience* (3); other phys. properties (4 classes—6 titles). H. B. MERRILL

Report of the International Commission on Leather Analysis. R. FARADAY INNES. *J. Intern. Soc. Leather Trades Chem.* **15**, 6–12(1931).—Current problems and recent advances are discussed. Topics include the detn. of H_2O, ash, fat and acidity in vegetable-tanned, and of basicity of Cr salt, fat, H_2O-sol. matter and N in Cr-tanned leathers. The theoretical basis of the Atkin-Thompson method (*C. A.* **23**, 4843) for acidity of vegetable-tanned leather—namely that the leather contains free amino groups that enable it to function like a gel with respect to acid—is questioned. Infusions of leather in H_2O and in 0.1 *N* KCl do not differ appreciably in p_H value. Failure of petr. ether completely to ext. sulfonated oils and Al soaps is pointed out. H. B. M.

[Methods employed in] Chinese leather centers. H. A. BRAUNSTEIN. *Hide and Leather* **81**, No. 4, 30 (1931). H. B. MERRILL

Emulsions and suspensions in the leather industry. A A. CLAFLIN. *J. Am. Leather Chem Assoc.* **25**, 544–50(1930).—An address. H. B. MERRILL

Photomicrographic methods for determining the kind of leather and its defects. F. FEIN. *Collegium* **1930**, 593–8.—The method is briefly described. Eight photomicrographs (×28) of sheep, horse, calf and goat leathers are reproduced. I. D. C.

The international commission on the analysis of artificial bates. V. KUBELKA. *Collegium* **1931**, 16–21.—The literature since 1928 is reviewed and the problems yet to be solved are stated. A number of substances have been proposed as substrates but casein is most used. The casein method is not yet satisfactory. Also in *J. Intern. Soc. Leather Trades Chem.* **15**, 56–60(1931). I D. CLARKE

Enumeration (counting) of bacteria in soak waters. GEO. E. ROCKWELL. *J. Am. Leather Chem. Assoc.* **26**, 2–7(1931).—In sampling, a piece of skin should be included. Correct diln. may vary from 1:10 to 1:1,000,000, depending upon the type of soak water. In plating, 1 cc. of a fresh meat ext. is added to the dish, followed successively by 1 cc. dil. soak water and the agar. Incubation at 37° for 24 hrs., followed by 24 hrs. at room temp., is advised. H. B. MERRILL

The problem of improving the quality of the hides. A. GANSSER. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* **8**, 110–5(1930). G. SCHWOCH

Contribution on hide damages by M. Bergmann and collaborators. IX. Bacteriology of the reddening of salted hides. WILLI HAUSAM. *Collegium* **1931**, 12–6, cf. *C. A.* **24**, 262.—A description is given of bacteria, other than those described previously, which have been isolated from red stained hides. I. D. CLARKE

Raw-skin defects and their effect on leather. FRITZ STATHER. *Collegium* **1931**, 3–12.—A summary of present knowledge of skin defects and damages. I. D. C.

Use of sulfide-lime liquors in the sterilization of hides infected with anthrax. M. E. ROBERTSON. *Leather World* **22**, 407, 488, 590, 670, 792(1930); *J. Am. Leather Chem. Assoc.* **26**, 120; cf. *C. A.* **24**, 4653 and following abstr. H. B. MERRILL

Use of sulfide-lime liquors in the sterilization of dried hides infected with anthrax. IV. Experiments on China hides. DOROTHY JORDAN LLOYD AND MADGE E. ROBERTSON. *J. Intern. Soc. Leather Trades Chem.* **14**, 641–57(1930); cf. *C. A.* **24**, 4653.—Pieces of hide known to be infected (from guinea-pig inoculations) were treated with lime-sulfide soln. at various temps. for different time periods, neutralized, triturated, extd., the ext. was centrifuged, and guinea pigs were inoculated with the deposit. The proportion of positive results increases with the vol. of ext. taken for centrifuging, showing that a relatively small no. of organisms are very resistant to treatment. Complete sterilization, with little or no damage to hides, was attained by treating them for 8 hrs. at 32° in a soln. contg. 1.0% $Na_2S.9H_2O$, + 1.2% CaO followed by a 4-day treatment at room temp. Higher temps. and (or) sulfide concns. ruined the hides. Fairly certain disinfection results at temps. down to 20° if the time is increased, but below 20° disinfection is very slow and uncertain Cf. preceding abstr. H. B. MERRILL

Estimation of total sulfuric acid in hides. X. K. A. BUSHMAN. *Ukrainskii Khem. Zhur.* **5**, Tech. Pt., 113–5(German Abstract 116)(1930).—The method is based upon the chlorination principle applied by A. P. Sementzev and V. L. Pavlov to the detection of As in the intestinal tract of animals and man (*Arch. Crim. and Med. Jurispr* **1**, 43(1926)). Place 4–5 g. of finely cut hide in a 1.5-l. flask; add 25 cc. distd. water and 10 g. NaOH; heat gradually to boiling and when the hide is almost dissolved add 80 cc. water and continue boiling till the hide is completely dissolved. Cool in ice water and introduce a moderate stream of Cl_2 gas for about 15 min. From time to time add distd. water until a final vol. of about 150 cc. is reached to prevent sepn. of NaCl crystals. At the end of 15 min., acidify with HCl and remove the Cl_2 gas by bubbling air through the soln. Filter and to the filtrate add a 3% soln. of hot $BaCl_2$. B. S. L.

Hydration of goat skin. EDWIN R. THEIS AND ADOLF GRYNKRAUT. *J. Am. Leather Chem. Assoc.* **26**, 134–43(1931).—Hydration during soaking and liming is followed by the dilatometer method (*C. A.* **23**, 2319). With H_2O max. hydration was attained in 14 hrs., followed by degenerative dehydration ascribed to bacterial or enzyme actions. HCOOH in soak decreases and delays attainment of max. hydration; this effect increases with increasing HCOOH concn.; the onset of degenerative changes is correspondingly postponed but not otherwise affected. NaOH in soak delays the attainment of, but does not decrease the extent of, max. hydration, and does inhibit degenerative dehydration. Extent of max. hydration and time required for its attainment are both decreased by increasing the temp. of the soak. Hydrations produced in soaking and in subsequent liming are largely additive. In soaking dried skins, hydration seems to take place in 2 stages, the second of which is shorter, and results in more hydration than the first. H. B. MERRILL

Principles of the liming process. R. H. MARRIOTT. *Leather World* **22**, 305 (1930); *J. Am. Leather Chem. Assoc.* **26**, 116.—The liming process has 2 functions: to remove the hair and to plump and sep. the fibers in prepn. for tanning. The conditions of liming should be regulated so that both aims are achieved simultaneously. Plumping of the fibers results in a characteristic "weave" which is described as flat or steep; the optimum condition depends upon the kind of leather. Unhairing results from the action of alkali on keratin, which is promoted by reduction of cystine linkages before the alkali has acted. H. B. MERRILL

[Some] details of leather manufacture. FINI G. A. ENNA. *Hide and Leather* **80**, No. 11, 21(1930).—Soaking green-salted skins prior to liming is unnecessary. NaCl, blood, etc., carried into lime when soaking is omitted are without detrimental effect. Omission of soaking avoids bacterial damage. For dried hides, neither acid soaking nor alk. soaking is to be recommended. Salts are effective in the order: $NH_4Cl > (NH_4)_2SO_4 > CaCl_2 > NaCl$. Some tanners put dried hides directly into strong Na_2S and lime, for combined soaking-unhairing, with good results; a soln. contg. 1.25% NH_4Cl and 1.25% Na_2S (60 %) is an effective softener. H. B. MERRILL

Processes of patent-leather manufacture. F. G. A. ENNA. *Leather World* **22**, 36, 116, 196, 412, 593(1930); *J. Am. Leather Chem. Assoc.* **26**, 118.—A description. H. B. MERRILL

Hazards in the manufacture of patent leather. E. H. MERRILL. *Hide & Leather* **80**, No. 14, 19(1930); *J. Am. Leather Chem. Assoc.* **26**, 36.—The naphtha fire hazard is discussed. H. B. MERRILL

Acidity of leather. H. G. BENNETT. *J. Intern. Soc. Leather Trades Chem.* **15**, 31–8(1931).—The "acid figure" of Atkin and Thompson (*C. A.* **23**, 4843), which is believed to be the p_H value of the concd. soln. of tannin on the outer part of the fibers, can be obtained arithmetically as well as graphically from measurements of p_H value at known dilns. in 0.1 *N* KCl. p_H (at any diln.) = tan θ log d + F, where tan θ = slope of the p_H-diln. plot, d = diln. and F = acid figure, or p_H at zero diln. Tan θ is thought to be fully as important as F. Two points are sufficient to det. the p_H-diln. plot, and calcns. are simplified if these 2 p_H values whose logs are simple integers are detd. at fixed dilns.; *e. g.*, diln. = 100-fold and 1000-fold; log d = 2 and 3. To find the proper wt. of leather to take to obtain these dilns. when the leather is soaked in 100 cc. of 0.1 *N* KCl, det. the % H_2O (W) and weigh $101W$ g. for 100-fold, and $10.1W$ g. for 1000-fold diln. If p_H values of these solns. are $(p_H)_2$ and $(p_H)_3$, then $F = 3(p_H)_2 - 2(p_H)_3$, and p_H (at any diln.) = $[(p_H)_3 - (p_H)_2]$ log d $- F$. Examn. of many leathers (chiefly sole) selected as representative com. products showed only 1 leather for which $F < 2.5$, and av. value of F was 3.5. Generally a high value for F is assocd. with a low value for tan δ; that is, with a well-buffered leather; and this is due often to the presence of appreciable amts. of Na salts. H. B. MERRILL

Application of the Atkin-Thompson method for acidity to vegetable-tanned calf leather. HENRY B. MERRILL AND REUBEN G. HENRICH. *J. Am. Leather Chem. Assoc.* **25**, 511–7(1930); cf. *C. A.* **23**, 4843.—Data are presented which indicate that the method gives results on leathers tanned with so-called spruce ext. (which is high in sulfonated bodies) that are rational and self-consistent, in contrast to results given by the Procter-Searle method. H. B. MERRILL

Present state of the determination of wear resistance of leather and methods for bettering it. U. J. THUAU. *J. Intern. Soc. Leather Trades Chem.* **14**, 602–23(1930); cf. *C. A.* **23**, 1768, 4096; **24**, 2634, 4654.—An improved wear test machine is described. For standardization, a plate of pure Cu, previously heated to 600° for 15 min., is employed, and all wear resistances are expressed in terms of this standard taken as 100. Soles are rubbed across a Carborundum plate under pressure of 70 kg. (av. human wt.),

Accessory gadgets assure a clean and uniform wearing surface at all times. Results are expressed in cm.^{2} of abrasive surface with which 1 cm.^{2} of leather must be brought into contact in order to wear off a layer 1 mm. thick. As the ratio of abrasive surface to leather surface exposed at a single revolution is 1:1, the coeff. of resistance is directly proportional to the no. of revolutions and inversely proportional to the thickness removed. The latter is obtained from wt. loss and density measurements. The coeff. of resistance varies with time, generally increasing after the grain layer has been worn away; curves are given for numerous leathers. Results are given for numerous kinds of sole leather and substitutes. Wear resistance of vegetable-tanned leather is increased by retannage with chrome, by previous acid swelling of the pelt, and by increasing its resistance to extn. by H_2O. The superiority of leathers tanned by the "slow" process is ascribed to their relatively low content in matter extractable by H_2O. *Hardness* is measured by the Brinell machine. H. B. MERRILL

Little trips to tanneryland. I. Wild grain. JOHN A. WILSON. *Hide and Leather* **81**, No. 7, 8(1931).—Wild grain is caused by overdevelopment of the blood-vessel system supplying the sebaceous glands. It can be minimized by proper control of all tannery operations. H. B. MERRILL

Report of the commission on qualitative analysis of tannins. O. GERNGROSS. *Collegium* **1930**, 524–32; cf. *C. A.* **25**, 230.—The aniline-HCl, cinchonine and fluorescence tests for sulfite cellulose were generally in agreement. Pine and malet to bark exts. interfere with the fluorescence test in its present form. I. D. CLARKE

Report of the commission on quantitative tannin analysis. M. BERGMANN. *Collegium* **1930**, 573–4; cf. *C. A.* **23**, 4592.—A review. I. D. CLARKE

Rapid tanning. MAX BERGMANN, WILLY MÜNZ AND LUDWIG SELIGSBERGER. *Collegium* **1930**, 520–4.—Neradol N D and α- and β-naphthalenesulfonic acid solns. pass through skin more rapidly than H_2O does; therefore they enlarge the skin capillaries. But the total H_2O of swelling and imbibition is less and so the H_2O of swelling must be less (H_2O of imbibition is greater since the capillaries are larger) in these solns than in H_2O. Agents to increase the speed of tanning may not only decrease the size of the tannin particles but may act on the hide to decrease resistance to penetration Also in *J. Intern. Soc. Leather Trades Chem.* **15**, 67–72(1931.) I. D. CLARKE

The enzymes of tanning chemistry and the structural-chemical explanation of their action. MAX BERGMANN. *Collegium* **1930**, 516–20.—Studies of some reactions of protein-building units are reviewed; these studies should aid in explaining the mechanism of those reactions of proteins which are catalyzed by enzymes. I. D. CLARKE

Filtration of tannin solutions for the determination of insolubles. A. L. C. A. Committee Report, 1930. J. S. ROGERS, *et al. J. Am. Leather Chem. Assoc.* **25**, 493–510(1930).—For the purpose of this investigation, "insolubles" are defined as substances which render the tannin soln., of analytical strength, at 18°, cloudy, turbid or opalescent by either reflected or transmitted light. Methods studied are (1) the International Method and the methods of (2) Turnbull (*C. A.* **23**, 2596), (3) Riess (*C. A.* **23**, 3369, 4592) and (4) McCandlish-Atkin (*C. A.* **23**, 3368); solid quebracho, chestnut, hemlock and "valex" exts. were used. In all cases the solns. were filtered until a clear filtrate was obtained, after which 2 successive portions were collected, pipetted, evapd. and weighed. Results (regarded as preliminary) indicate that the International Method returns too low insolubles and does not always give clear filtrates; that the other 3 methods do give clear filtrates; and that of these the Riess method is most promising from the standpoint of app. and manipulation. H. B. MERRILL

The tannin balance in the extraction of pine bark. E. BELAVSKY AND G. WANEK. *Ledertech. Rundschau* **23**, 1–4(1931).—The tannin balance for pine bark and the ext showed a gain of 8.38% if the raw and spent bark were analyzed by the International Method but only 0.39% if the method was modified to give max. results. Completeness of extn. is affected by many factors such as temp., time and the percentage which the ext. is of the raw material but the greatest loss of tannin is always in the extd. bark. I. D. CLARKE

Determination of the copper content of tanning extracts. Committee report. D. BURTON. *J. Intern. Soc. Leather Trades Chem.* **15**, 99–106(1931).—Cu in exts is even more objectionable than Fe. Cu is always estd. in the ext. ash. Of numerous procedures tested, electrolytic deposition from H_2SO_4 soln. is recommended. *Procedure.*—Dry 50 g. ext. in an oven, ash at min. temp., moisten with H_2SO_4, expel chlorides, dissolve in 10 cc. 2 *N* H_2SO_4 and dil. to 100 cc. Electrolyze overnight at 2 v. Wash with H_2O, then with EtOH (abs.), dry at 100° and weigh. H. B. MERRILL

The determination of the color of tanning extracts. G. BALDRACCO. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* **8**, 100–9(1930).—The different methods are reviewed. The Pulfrich stage photometer is considered as the instrument most suited for the detn. of the color of tanning exts. G. SCHWOCH

Determination of the p_H (value) of tanning extracts. D. BURTON, *et al.* *J. Intern. Soc. Leather Trades Chem.* **14**, 597–601(1930).—The quinhydrone method is unsuitable. The bubbling H_2 method gives accurate results with exts. that are not sulfited. The glass electrode method (*C. A.* **23**, 4365) is suitable for use in all types of tannery liquors. Working directions for the 2 latter methods are given. H. B. MERRILL

Importance of the p_H of the pelt in tanning. G. PEACE. *J. Intern. Soc. Leather Trades Chem.* **15**, 22–4(1931).—It is a mistake to assume that the pelt speedily assumes the p_H value of the tan liquor in which it is placed, and to center attention on the p_H value of the liquor. Heavy hides, especially, should be brought to the optimum p_H value (which generally lies in the p_H range 5 to 3) before entering the tan liquors. This procedure makes it unnecessary to add acid to the tan liquors, permits rapid tannage and satisfactory plumping in liquors of moderate acidity, greatly simplifies control and makes for numerous operating economies. H. B. MERRILL

Determination and control of the buffer index of tan liquors. WINNIFRED B. PLEASS. *J. Intern. Soc. Leather Trades Chem.* **15**, 73–8; *Leather World* **23**, 35(1931).—The detn. of effective acidity (p_H) should be accompanied by that of reserve acidity (buffer index). The latter is defined as "the no. of cc. of *N* NaOH or HCl required to be added to 100 cc. of a tan liquor of 20° barkometer (sp. gr. = 1.020) to alter its p_H value by 1 unit." The buffer index should be estd. on a portion of the titration curve covering at least 2 p_H units, in the p_H range 2.5–5. This involves titration with NaOH for liquors of low p_H, and with HCl for liquors of high p_H; liquors of p_H value = 3.0–4.5 must be titrated with both. If the barkometer of the undiluted liquor is less than 20°, the buffer index at 20° is obtained by simple proportion. Generally speaking, a high buffer index is given by old, mellow liquors, rich in non-tannin or sol. Ca salts (such as bottom suspenders). The buffer index should decrease from the oldest liquor in a series to about the mid-point, and should be approx. const. for the remaining (fresher) liquors. Sharp differences in buffer index between successive liquors are objectionable. The buffer index increases with increasing non-tannin/tannin ratio in the tanning materials used, is increased by adding lactic acid, and decreased by adding H_2SO_4. A high buffer index results in the production of a soft, full leather; a low buffer index results in a firmer, harder leather. H. B. MERRILL

Determination of p_H value of tannery liquors. W. B. PLEASS. *Shoe & Leather Reporter* **80**, No. 12, 21(1930); *J. Am. Leather Chem. Assoc.* **26**, 111.—The glass electrode is recommended as most reliable, with the capillator second. H. B. MERRILL

The basicity concept of one-bath chrome liquors. E. STIASNY. *Collegium* **1930**, 574–7.—The basicity of the Cr salt in a one-bath Cr liquor is greater than that of the liquor as a whole because of "olation"; the complex ol. compds. react with the free acid only very slowly. It is important to know the basicity both of the liquor and of the Cr salt. The former is given by the formula $[(a-b)/b]100$ and the latter by $[(a-b+c)/a]100$, in which a is the no. of cc. of 0.1 *N* $Na_2S_2O_3$ used in the iodometric detn. of Cr (in 25 cc. of liquor), b is the no. of cc. of 0.1 *N* NaOH used in titrating the liquor as usual (to phenolphthalein) and c is the no. of cc. of 0.1 *N* NaOH used in a cold titration to p_H 3.0 with *p*-benzenesulfonic acid-azo-benzylanilide. At p_H 3 only the free acid in soln. is detd. I. D. CLARKE

Origin of ammonia found in lime liquors. R. H. MARRIOTT. *J. Intern. Soc. Leather Trades Chem.* **15**, 25–30(1931).—Collagen from oxhide and degreased oxhair was treated with satd. $Ca(OH)_2$ for periods of 8–72 days. Total N and volatile N were detd. in the used liquors. The undissolved proteins were washed and hydrolyzed by 20% HCl. Hydrolyzate was analyzed for NH_3 and total N. With collagen, the amt. of NH_3 found in the liquor agrees almost quantitatively with the observed decrease in amide N in the protein; with hair, more NH_3 is formed than can be accounted for by the decrease in amide groups; the excess is supposedly due to breakdown of cystine groups. Amide N is removed very much faster both from hair and from collagen than is non-amide N. H. B. MERRILL

Preparation and preservation of sheepskin skivers for color tests [on tanning materials]. Committee Report, 1929–30. C. A. BLAIR, *et al.* *J. Am. Leather Chem. Assoc.* **25**, 550–61(1930).—Two methods for depickling and preservation are investigated with pickled skin as the starting material: (1) The skin is suspended in 5% NaCl soln. and the acid titrated repeatedly to the neutral point, until the skin no longer swells when placed in H_2O. The skin is preserved in satd. NaCl soln. (2) Excess

borax is used and the excess neutralized with dil. AcOH. The p_H is adjusted to 4.8 with acetate buffer; the skin is preserved in phenol-boric acid soln. p_H values of solns. in equil. with skivers prepd. according to (1) are not very uniform. Method 2 is generally preferred, although the borophenol causes some darkening of the skiver on long storage. H. B. MERRILL

Treatment of tannery wastes. Condensed report to the Sanitary Water Board. TANNERY WASTES DISPOSAL COMMITTEE OF PENNSYLVANIA. *J. Am. Leather Chem. Assoc.* **26**, 70–110(1931).—Two main plans of waste treatment were developed and given long tests under full-scale operating conditions in a small vegetable leather tannery. Depending upon the degree of purification required, which in turn depends upon the type of wastes, type of stream and vol. of wastes compared to stream vol., 1, 2, 3 or all 4 of the following steps may be required: mixing and settling; primary filtering and settling; chem. coagulation; secondary filtering and settling. The above is a general scheme, believed to be applicable to any tannery. A special scheme consists in segregating and chemically pptg. certain wastes, followed by filtering and settling. Spent tan liquors and bleaches are the forms of pollution most difficult to treat, and arrangements should be made to discharge them at a uniform day-to-day rate. Sludge should be removed at regular intervals; cinder bed drying is satisfactory. Cost data and detailed drawings of the exptl. plants are given. H. B. MERRILL

Tanning shark skins. F. A. COOMBS. *Hide & Leather* **80**, No. 11, 24(1930); *J. Am. Leather Chem. Assoc.* **26**, 110.—A description. H. B. MERRILL

Nature of water solubles in leather tanned with wattle bark extract. II. R. O. PAGE AND H. C. HOLLAND. *J. Am. Leather Chem. Assoc.* **26**, 143–56(1931); cf. *C. A.* **23**, 541.—Soaked, limed and bated steer hide was tanned for 6 weeks with wattle bark ext. at p_H 4; thereafter it was tanned at p_H values of 4, 3 and 2 for periods up to 2 yrs. Analyses were made at the end of 3, 6, 26, 52 and 104 weeks, the authors' method for free and combined H_2O-sol. matter being used. At the outset, fixed tannin rises rapidly to 30 g. per 100 g. collagen, with little combination of H_2O-sol. matter; in the 2nd stage, tannin slowly increases and combined H_2O-sol. matter rises to about 30 g per 100 collagen; in the final stage (3 months to 2 yr.) fixed tannin continues to rise, approaching a max. of 60 parts per 100 collagen, while combined H_2O-sol. matter remains stationary. The p_H value in the 2nd and final stages is without effect on combined H_2O-sol. matter; fixed tannin increases slightly with decreasing p_H value in the range studied. In expts. with hide powder, with different ratios of wattle ext. solids to collagen, the ratio, fixed tannin: combined H_2O-sol. matter, declines steadily with increasing ratio of ext. to collagen; the percentage of the total ext. solids removed from the soln. is nearly independent of the ratio of the ext. to collagen, decreasing slightly in the more concd. solns., which show the presence of tannin by the gelatin-salt test after tanning is complete; for the more dil. solns., the % of the total ext. solids thus removed as fixed tannin and combined H_2O-sol. matter is very nearly the % of tannin in the ext. according to the A. L. C. A. Method. These results are explainable on the assumption that collagen combines with tannin to form a compd. highly resistant to washing (fixed tannin), then with more tannin to form a compd. less resistant to washing (combined H_2O-sol. matter). The fixed tannin and combined H_2O-sol. matter are thus the same substances differently combined. The A. L. C. A. Method for detg tannin is approx. correct; that of Wilson and Kern is in error. The effect of the p_H value was studied at 15° and 35° for 6-weeks' tannage. At 15° both fixed tannin and combined H_2O-sol. matter are at a min. at $p_H = 5$; at 35° this min. vanishes, and fixation decreases from $p_H = 3$ to $p_H = 8$. Fixed tannin is much greater, and combined H_2O-sol. matter somewhat less at 35° than at 15°. By treatment with dil. H_2SO_4 at temps. from 35° to 60°, most of the combined H_2O-sol. matter is fixed as tannin. When a leather so treated is retanned, fixed tannin does not increase but combined H_2O-sol. matter reassumes its former value (before the heat-acid treatment). The change of state of combination is ascribed to changes in the collagen and not in the material fixed originally as combined H_2O-sol. matter. The recurrence of the factor 30 in the ratios of fixed tannin and (or) combined H_2O-sol. matter to collagen suggests that the combining ratio of wattle tannin to collagen is 100:30, giving a combining wt. of 225 (if collagen is 750) for wattle tannin. Conclusion: Combined H_2O-sol. matter is tannin, combined in a manner different from fixed tannin. H. B. MERRILL

Deterioration of vegetable-tanned leather in storage. R. FARADAY INNES. *Intern. Soc. Leather Trades Chem.* **14**, 624–40(1930).—Old book bindings were analyzed for H_2SO_4 (Procter-Searle method), "difference figure" (*C. A.* **23**, 4367), sol. N and grease. Comparison of backs (exposed) and sides (less exposed) showed that large amts. of SO_2 are absorbed from the atmosphere, particularly in industrial cities. Ex-

amination of books kept side by side for many years shows that leathers differ in their absorptive capacity for SO_3; the absorption may be a result rather than a cause of the rotting. All rotted bindings were very high in H_2SO_4, but not all leathers high in H_2SO_4 were rotted; an extreme case is a leather contg. 4.7% H_2SO_4 which was sound after 42 yr. Sol. N is proportional to H_2SO_4, and like it is not directly related to deterioration. It is thought that the kind of tanning material dets. whether or not a large H_2SO_4 content is harmful. Other factors may be: phys. condition of fibers resulting from pre-tanyard operations; lack of grease; overtannage. It is advised that bookbinding leathers be tanned with oak bark or sumac only, and that H_2SO_4 be not used after tannage is complete. The use of H_2SO_4 for deliming and pickling has no ill effect. H. B. MERRILL

The action of pickles of different compositions. II. Acid absorption and swelling of collagen in sulfuric acid and formic acid pickles. A. KÜNTZEL AND W. PREISENTANZ. *Collegium* **1930**, 577–93; cf. *C. A.* **24**, 4654.—A H_2SO_4 pickle, whether it contains NaCl or Na_2SO_4, behaves like a HCl pickle. The absorption values for H_2SO_4 are the same as those for HCl; the calcns. given previously for HCl apply to absorbed H_2SO_4 in H_2SO_4-Na_2SO_4 pickles without reservation but for H_2SO_4-NaCl pickles the NaCl influences the absorption of H_2SO_4 so that a correction (max. absorption is 0.6 instead of 0.7 equivs.) must be applied. The swelling weights of collagen are analogous to those in HCl-NaCl pickles; the abs. values, however, become smaller as Cl^- is replaced by SO_4^{--} (swelling in HCl-NaCl > in H_2SO_4-NaCl > in H_2SO_4-Na_2SO_4 pickles). Systems contg. weak org. acids are entirely different; the rising portion of the absorption curve is not linear and the absorption of acid is either greatly decreased (lactic) or greatly increased (acetic, formic) by the salt content of the pickle. The pickling or de-swelling actions of NaCl and Na formate on formic acid are exactly the same although the former has no, and the latter a great, influence on the p_H. These results disprove Procter's theory that all pickles contg. NaCl, regardless of the kind of acid, behave like HCl pickles. They also disprove the theory that the swelling action of weak org. acids can be repressed by buffering. Salts repress swelling because of their pickling action and regardless of whether they have a buffering action or not. I. D. CLARKE

Report of the oil and fat commission. M. AUERBACH. *Collegium* **1930**, 532–4.—A brief discussion of general methods. I. D. CLARKE

Dyestuffs and leather. W. E. NORTON. *Leather Trades Rev.* **63**, 640, 739(1930); *J. Am Leather Chem. Assoc.* **26**, 51.—Uneven coloring on Cr leather is ascribed (1) to uneven acid distribution in leather due to prolonged "horsing" before coloring and (2) to the presence in the dye mixt. of dyes that penetrate and fix at different rates. Over-mordanting increases rubbing of the color. Sufficient penetration must be secured so that the leather does not appear lighter in shade when it is stretched. Penetration is secured by using acid dyes, adding acid to the dye bath and slow drying of the dyed leather. Basic and direct dyes should be used for topping off—not for bottoming, and they should never be used in a bath with acid dyes. Practical working directions are given for various types of leather and special color effects. H. B. M.

Osage orange and yellow wood extract. G. DESMURS. *Leather World* **22**, 201 (1930); *J. Am. Leather Chem. Assoc.* **26**, 116.—Formulas are given for using yellow or Cuba wood ext. in dyeing Cr leather The following test is used for differentiating osage orange from wood: Measure 10 cc. of 0.4% ext. into a test tube, and add 2.0 cc. of a 1.0% U nitrate soln. Colors produced are: osage orange, a full orange-red; Cuba wood, yellow-orange. Other tests are given. H. B. MERRILL

Technical preparation of glue and gelatin. D. GURIAN *Kolloid-Z.* **54**, 239–43 (1931); cf. *C. A.* **25**, 1408.—A review of German patents. A. FLEISCHER

Influence of pancreatin on collagen in the absence of neutral salts and buffer mixtures (KÜNTZEL, DIETSCHE) **11A.** Tests on artificial leather (HESSE) **26.** Glass electrode and vacuum-tube potentiometer [in tannery analyses] (CAMERON) **1.** Treating fibrous materials with rubber, etc. [for making artificial leathers] (Brit. pat. 337,359) **25.** Protein products resembling horn (Brit. pat. 338,015) **25.** Apparatus for continuous filtration and dehydration of pulp for artificial leather manufacture (Brit. pat. 337,346) **23.**

Dressing leather. OTTO L. STEVEN. Ger. 514,723, July 23, 1927. See U. S. 1,750,732 (*C. A.* **24**, 2635).

Leather. HERMANN BOLLMANN and BRUNO REWALD. Ger. 517,353, Dec. 8, 1927, and 517,354, Feb. 24, 1928. A substitute for yolk of egg in the manuf. of glacé leather comprises an aq. soln. of an aromatic or aliphatic sulfonic acid or sulfonate and a phos-

phatide of vegetable or animal origin, with or without a vegetable albumin, *e. g.*, soybean albumin. An example is given (517,353). Alternatively there may be used an emulsion of vegetable or animal albumins and phosphatides prepd. by dissolving the albumins in water contg. a small quantity of alkali and then adding the phosphatides, which may be first dissolved in a fatty oil (517,354).

Leather. CARL H. TRÖGER, JR. Ger. 517,102, July 26, 1928. Vegetable-tanned leather is treated, before drying, with a bleaching bath to which substances promoting fermentation, *e. g.*, yeast, have been added. In this way the time required for drying is considerably reduced.

Tanning. W. SAILER. Brit. 337,377, April 30, 1929. Hides are treated with a liquor prepd. by treating sulfite cellulose lyes with oxidizing compds. such as perborates or persulfates followed by treatment, about 2 hrs. later, with Cl or Br. Pelts may be preliminarily treated with the liquor and then depilated. Cf. *C. A.* **25**, 2019.

Rotary-drum apparatus for tanning skins. E. G. WILSON. Brit. 337,408, July 22, 1929. Structural features.

Tanning agents. I. G. FARBENIND. A.-G (Ludwig Teichmann and Hermann Noerr, inventors). Ger. 517,446, Jan. 3, 1929. See Fr. 687,411 (*C. A.* **25**, 839).

Tanning agents. J. R. GEIGY AKT.-GES. Swiss 141,788 and 141,789, July 30, 1928. Addns. to 138,884 (*C. A.* **25**, 839). A weakly acid, powerful gelatin-depositing tanning agent is obtained by the reaction on Ω-chloromethylenesalicylic acid in dil AcOH suspension with Na naphthalene-β-sulfonate or Na *o*-cresol-*p*-sulfonate. Cf *C. A.* **25**, 839.

Tanning hides. O. RÖHM. Brit. 337,524, Dec. 6, 1928. A substitute for egg yolk suitable for use in the manuf. of glacé leather consists of an oil emulsion and one or more esters formed from di- or poly-hydric alcs. and H_3PO_4. These constituents may be used in a tanning liquor together with meal, alum and NaCl.

Tanning skins. J. R. GEIGY A.-G. Ger. 514,874, July 7, 1925. The depilated skins are treated with mineral acid and neutral or basic Cr, Al or Fe salts. They are then treated, in the same bath or in a separate soln., with neutral synthetic tanning material, the soly. of which, in water, depends on the presence of the HSO_3 group. Sulfite cellulose lye may be also used for further steeping of the skins. In an example, the skin is pretreated with Cr alum and tanned with the condensation product of CH_2O and cresolsulfonic acid. Other examples are given.

Moistening and "wetting out" leather and hides. FRIEDRICH POSPIECH (to Chemische Fabrik Pott & Co.). U. S. 1,794,920, March 3. Thorough moistening is effected with an aq. soln. contg. sulfonic acids of a compd. obtained by condensing naphthalene or a ring substitution product of naphthalene such as naphthalenesulfonic acids in the presence of condensing and oxidizing agents such as H_2SO_4 with an alc of the aliphatic series contg. over 2 C atoms such as Pr or Bu alcs., cyclohexanol, etc

Glue. BENNO NORDON. Ger. 517,098, Dec. 30, 1928. Glue liquid in the cold is prepd. by treating animal glue with $HClO_4$. Thus animal glue 10 dissolved as usual in water 15 may be stirred with 20% $HClO_4$ 3 parts.

Glue and gelatin. HERMANN STREIDL. Ger. 514,721, Feb. 7, 1928. App. for molding is described.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The preparation of plantation rubber. G. MARTIN. *Bull. Imp. Inst.* **28**, 440–50 (1930).—A description is given of the methods of prepn. of plantation rubber used in Ceylon, Malaya and Java, with tables to show the differences in detail between the procedures followed in the 3 countries. Also in *Trop. Agr.* (Ceylon) **76**, 18–26(1931). A PAPINEAU-COUTURE

Liquid rubber compounding. WEBSTER NORRIS. *India Rubber World* **83**, No. 5, 53–5, 64(1931).—An illustrated description of recent developments in the preservation, diln., stabilization and neutralization of latex, mixing operations, typical compds. and industrial applications. C. C. DAVIS

Action of nitrogen oxide on rubber. ADOLF GORGAS. *Ber.* **63B**, 2700–5(1930).—Various observers have reported the formation of definite products by the action of NO_2 on rubber (Weber, $C_{10}H_{16}N_2O_4$; Emden, $C_{10}H_{16}N_2O_6$; Harries, Alexander, products of more complex compn.). These workers paid no particular attention to the purity of the NO_2. The best results were obtained with the gaseous decompn. prod-

ucts of $Pb(NO_3)_2$; Emden used the product obtained from HNO_3 and starch. G., on the other hand, carefully purified his NO_2, which was prepd. from HCHO and concd. HNO_3. The resulting mixt. of N_2O_3 and N_2O_4 was liquefied in a freezing mixt., completely converted into N_2O_4 with air, frozen, repeatedly crystd. and fractionated by distn. For the reaction with rubber the N_2O_4 was used in CCl_4 soln. satd. at room temp. Total rubber, prepd. from "Revertex" according to Pummerer and Pahl by treatment with alkali at 50° and subsequent dialysis, was used in 1% soln. in CCl_4. This rubber, as has been described elsewhere (*C. A.* **23**, 1525), gave by the modified Hanus method I nos. agreeing well with the calcd. values, and the sol and gel rubbers prepd. from this total rubber also gave normal I values (1 mol. I per C_5H_8 group). Contrary to Pummerer and Mann, G. found for the gel rubber with BrI an I no. about 10% too low instead of too high. By the Kaufmann $(SCN)_2$ method, the 2 rubbers showed no appreciable difference. The nitrosation was effected by adding the rubber soln. to 5 parts of the N_2O_4 soln. at 0° and letting the mixt. stand 15 min. in 1 series of expts. and 24 hrs. in another. The compn. of the resulting products did not correspond to any of the formulas given by earlier workers, even after pptn. from Me_2CO with Et_2O, and the expts. showed decisively that abs. pure NO_2 does not form homogeneous products with purified rubber. As already pointed out by Alexander, the addn. of NO_2 is accompanied to a considerable extent by oxidation. The addn. reaction apparently does not give NO_2 derivs.; at least, G. has thus far been unable to effect a reduction to NH_2 derivs., but he did observe that when the product of the 24-hr. treatment with NO_2 is heated with concd. alkali, about 1/7 of the N is split off as NH_3, which makes it probable that the N is present as an NOH group (probably as an isonitroso ketone). In view of the strongly oxidizing action of NO_2, expts. were made with NO. As it reacts much more slowly than NO_2, the well-purified NO was passed for 4 hrs. through a very dil. soln. of rubber in CCl_4 at 20°. The product was non-pulverizable, and had a compn. (about $C_{15}H_{19}N_2O_{10}$), indicating that oxidation to a marked degree accompanied the addn. reaction. The product was also no more homogeneous or const. in compn. than that obtained with NO_2, and gave NH_3 with hot concd. alkali. With HNO_3 it is possible to keep the 2 reactions sep. Dil. HNO_3 and rubber give a N-contg. product which, however, is partially insol. in Me_2CO, and this insol. portion is N-free while the N in the sol. portion is split off as NH_3 by boiling alkalies. The formation of the N-contg. product can be prevented by complete removal with urea of the HNO_2 which is formed. The yellow pulverizable product is sol. in $PhNO_2$, $PhNH_2$ and dil. alkalies. G. hopes soon to be able to report its compn., mol. wt., etc. C. A. R.

The rubber era. T. L. Garner. *India Rubber J.* **80**, 643-8(1930).—An illustrated description is given of modern technical applications of rubber. C. C. Davis

The trend of American rubber development research. Arnold S. Smith. *India Rubber J.* **80**, 664–7(1931).—An English version (slightly abbreviated) of *C. A.* **24**, 4954. C. C. Davis

Industrial uses of rubber. H. E. Fritz. *Paper Mill* **54**, No. 3, 14, 16–7(1931).—An outline of the widening applications of rubber rendered possible by the discovery of the Vulcalock process of bonding rubber to metal, which permits of utilizing to better advantage the corrosion-resisting and abrasion-resisting qualities of rubber. A. P.-C.

Preparation of sheet rubber. R. O. Bishop. *Malayan Agr. J.* **19**, 14–21(1931).—A discussion is given of present-day methods for the collection and handling of latex, its coagulation, handling of the coagulated rubber and drying and packing of the rubber. C. C. Davis

Toxic substances in the rubber industry. XIX. Sulfur and its derivatives. P. A. Davis. *Rubber Age* (N. Y.) **28**, 513-4(1931); cf. *C. A.* **25**, 1117.—With proper ventilation, choice of individuals and cleanliness, no trouble is likely with S. Fifteen yrs.' experience showed no serious cases of conjunctivitis, dermatitis, etc., from exposure to S. C. C. Davis

Technical note on the use of certain solvents in solutions. H. Coulangeon. *Caoutchouc & gutta-percha* **27**, 15274-6(1930).—When a film of cement dries, the evapn. of the solvent causes a lowering of the temp., which may be great enough to reach the dew point and thus cause moisture deposit on the rubber. This results in poor adhesion when the surfaces are united. Since the lowering of the temp. varies with the solvent, it is possible to avoid this condensation of moisture by the proper choice of solvent for the conditions. Data were obtained on the lowering of temp. (wet bulb) of cements of the same viscosity made with solvent naphtha, toluene, aviation gasoline and benzene, resp., with the atm. at different temps. (10–30°) and humidities. By plotting the results graphically, the resulting chart shows under what conditions of temp. and humidity cements made with the various solvents can be used successfully without re-

course to warming, and under what conditions and to what extent warming is necessary.
C. C. DAVIS

Paragutta, a new insulating material for submarine cables. A. R. KEMP. *J. Franklin Inst.* **211**, 37–57(1931).—Gutta-percha and balata have proved themselves eminently suitable for insulating long deep-sea telegraph cables, but their dielec. losses are too high to meet the requirements of submarine telephone cables for long distances or for shorter cables with carrier currents. Accordingly an extensive investigation was made of the causes of elec. defects of submarine insulation, including a search for an improved material. One result was the development of a new material called *paragutta*, and the present paper describes its properties and tests for detg. its utility. Paragutta consists essentially of the purified balata or gutta-percha hydrocarbons, with a small proportion of waxes. In developing this mixt., it was necessary first to purify the rubber, especially to remove proteins, in order to increase its elec. stability on prolonged immersion in water. Rubber from which water-sol. substances have been removed absorbs no more water than does gutta-percha (cf. Williams and K., *C. A.* **21**, 1372, Lowry and Kohman, *C. A.* **21**, 1372; Boggs and Blake, *C. A.* **20**, 2092), but when immersed in water it fails completely as an insulator. To explain this elec. instability, rubber hydrocarbon freed of proteins, resins and other impurities was prepd. and tested. The product absorbed very little water, and on prolonged immersion in water it showed practically no change in elec. properties. Many expts. showed that the only practical method for removing proteins from rubber is to heat the rubber in an autoclave in water alone, which hydrolyzes the proteins to water-sol. products. Subsequent washing removes nearly all N. Sheet rubber or latex can be used for prepg. N-free rubber in this way. Thus ammoniated latex is diluted by addn. of 4 vols. of water, heated 10 hrs at 150° in an autoclave, cooled, coagulated with AcOH, washed thoroughly and dried The N content is then under 0.1%. When vulcanized, this deproteinized rubber is superior to ordinary rubber in its elec. stability in water. The deproteinized rubber is also more easily plasticized and mixed with gutta-percha than is ordinary rubber Paragutta is prepd. by blending deproteinized rubber with purified gutta-percha hydrocarbon, with the optional addn. of special hydrocarbons or montan wax. The proportions of the 3 components may be varied to suit the conditions. Thermoplastic insulators thus prepd. are almost like gutta-percha in mech. and elec. properties in water, and they are cheaper. Data show tensile, compression, flexibility, plasticity, brittleness, water absorption and elec. tests of paragutta in comparison with gutta percha. These data prove conclusively that paragutta behaves in almost the same way as gutta-percha in all these respects. It has the desirable thermoplastic and mech. properties of gutta-percha, and its superior insulating properties render it particularly adapted for transoceanic telephone cables. Paragutta is also of advantage for shorter deep-sea carrier telephone cables and for ocean telegraph lines. C. C. DAVIS

Reconditioning air bags by burning. CHARLES E. MAYNARD. *Chem. Met. Eng.* **38**, 91; *Rubber Age* (N. Y.) **28**, 565(1931).—A new machine is described for reconditioning air bags used in the vulcanization of rubber tires. It removes the hardened surface layer of used bags by burning and scraping, thus leaving a smooth surface and thoroughly reconditioning in one operation. C. C. DAVIS

Accelerators of vulcanization. Mercaptobenzothiazole. F. JACOBS. *Caoutchouc & gutta-percha* **28**, 15350–4(1931); cf. *C. A.* **25**, 1118.—The prepn. and properties of mercaptobenzothiazole are described, including its behavior and utility in rubber mixts **Mercaptides.** *Ibid* 15394–6.—By mercaptides are meant combinations of mercaptobenzothiazole with other accelerators having basic properties, *e. g.*, with hexamethylenetetramine, diphenylguanidine, di-*o*-tolylguanidine and ethylideneaniline. The behavior of some of these com. substances as accelerators is described, with examples to show their utility. C. C. DAVIS

Oxidation of vulcanized rubber mixtures extracted with acetone. T. YAMAZAKI AND K. OKUYAMA. *Caoutchouc & gutta-percha* **28**, 15359–60(1931).—See *C. A.* **24**, 4664. C. C. DAVIS

Activated carbons (SIMONIN) **18.** Modifying the properties of resins [for rubber-substitute manufacture] (Brit. pat. 337,733) **26.** Modifying isocolloids for rubber substitute manufacture (Brit. pat. 337,732) **26.** Improving elasticity of knitted artificial silk fabrics [for waist-bands, garters, etc.] (Brit. pat. 337,400) **25.** Waterproof coatings (Swiss pat. 142,172) **18.** Rubber-coated fabric (U. Rubber. I. G. FARBENIND. A.-G. (Julius Eisele and Johannes Stöhrel, inventors). Ger. 517,490, Sept. 13, 1927. Rubber latex is rapidly mixed with sufficient acid to establish a hydrion concn. greater than p_H 2, preferably greater than p_H 1, and a compd. reducing the surface tensions is then added, *e. g.*, Na β-naphthalenesulfonate or Turkey-red oil. The mixt. sets to an irreversible gel with sepn. of a small quantity of clear serum. Vulcanizing agents, accelerators or fillers may be added before or after the formation of the gel. Examples are given. Cf. *C. A.* **25**, 1706.

Rubber. SOCIETÀ ITALIANA PIRELLI. Ger. 517,208, Oct. 12, 1926. The aging properties of rubber are improved by addn. of about 5% of the evapn. residue of latex serum from which quebrachitol has been removed, *e. g.*, by crystn. Albumins may also be removed from the serum to be evapd., *e. g.*, by pptn. with tannic acid.

Rubber deposition. IMPERIAL CHEMICAL INDUSTRIES, LTD., and R. B. F. F. CLARKE. Brit. 337,946, Oct. 21, 1929. A hollow gas-permeable vessel, filled with CO_2 under pressure, is immersed in latex, and rubber is deposited on it as the CO_2 diffuses through the walls of the vessel and effects coagulation of the rubber deposit. Material to be impregnated may be wrapped around the vessel, and the vessel may be shaped to produce sheets or articles of other desired form.

Rubber composition. ELLWOOD B. SPEAR and ROBERT L. MOORE (to Thermatomic Carbon Co.). U. S. 1,794,558, March 3. A C black of the kind designated as "P-33" is used in making a rubber compn. having an ultimate tensile strength approx. the same as a similar rubber compn. contg. an equal wt. of "common com. C black" but having a stiffness materially less than such a rubber compn. An app. is described suitable for making the C from hydrocarbon gas. Cf. *C. A.* **24**, 212.

Rubber compositions. E. O COWPER. Brit. 338,247, June 5, 1929. Compns. suitable for covering athletic grounds, for use as *expansion joints, wall and roof coverings*, machinery beds, etc., are formed of latex from which the serum constituents have not been removed, mixed with waste rubber, rubber scrap, old tire stock or the like and with breeze, ashes, clinker, brick dust, baked clay, slate dust or the like; vulcanizing materials, pigments and bituminous or portland cement, etc., may also be added, as may also fibrous fillers. The material may be placed on a backing such as cloth or paper coated with bituminous material. Various details and examples are given.

Rubber composition suitable for tire treads, shoe soles, etc. ARTHUR B. COWDERY and THEODORE A. BULIFANI (to Barrett Co.). U. S. 1,793,161, Feb. 17. There is incorporated in a rubber mixt. a coal tar substantially free from cryst. material at 25°, having a sp. gr. above 1.06 at 38° and b. above 200°. Cf. *C. A.* **24**, 1545.

Coloring rubber. I. G. FARBENIND. A.-G. (Rudolf Krech, inventor). Ger. 517,450, Sept. 5, 1926. Rubber is mixed with an insol. metal salt of Patent Blue A, which may be deposited on a substrate. The colors obtained are fast to vulcanization. Examples are given.

Coloring rubber. DUNLOP RUBBER CO., LTD., D. F. TWISS, E. A. MURPHY and R. G. JAMES. Brit. 338,303, Oct. 11, 1929. Rubber articles obtained from aq. dispersions by dipping, spreading, painting, extruding, spraying, electrophoresis impregnating or molding are colored, locally or generally, after formation, by reaction between successively added substances which together form a desired coloring substance and one of which if desired may be added to the initial dispersion, *e. g.*, β-naphthol may be initially added and subsequently combined with a diazo soln., or the formed article may be dipped in indigo white soln. and subsequently oxidized, or an article formed by use of acid may be dipped in an alk. sulfide soln. of a S dye.

Preserving rubber. MARION C. REED (to B. F. Goodrich Co.). U. S. 1,793,635, Feb. 24. *Asym*-diphenyl- or other diaryl-hydrazine (suitably in the proportion of about 0.1–5.0%) is added to rubber compns. as a preservative.

Rubber dispersions, etc. DOUGLAS F. TWISS and EDWARD A. MURPHY (to Dunlop Rubber Co., Ltd.). U. S. 1,793,265, Feb. 17. For the production of substantially reversible compns. of pasty consistency from aq. dispersions contg. rubber or similar materials and a protective colloid, the dispersions are evapd. in the presence of one or more substances such as glycerol, glycol or a glycol alkyl ether, having as their principal function to serve in place of water as a medium in which the protective colloids, both naturally occurring and artificially incorporated, will continue to function when the water in the dispersions is substantially removed.

Making thin rubber bathing caps. MELVIN S. LOWER (to Sun Rubber Co.). U. S.

1,794,192, Feb. 24. App. and various details (mainly of mech. character) are described.

Rubber footwear. JAMES B. CROCKETT (to Cambridge Rubber Co.). U. S. 1,795,075, March 3. A last is dipped into an aq. rubber-contg. material contg. a coloring agent to form a deposited coating on the last, and the coated last is then dipped in an aq. rubber compn. of different coloring and the sole portion of the article is selectively dipped in an aq. rubber compn. contg. fillers for increasing the resistance of the sole to wear.

Molded rubber footwear. H. C. L. DUNKER. Brit. 337,831, Aug. 9, 1929. Articles such as galoshes or "seaside shoes" are formed by molding over a prevulcanized lining drawn onto the last and there covered with unvulcanized rubber to be molded.

Rubber battery boxes, etc. J. FERGUSON & SONS, LTD., and J. E. FERGUSON. Brit. 338,114, July 10, 1929. Boxes are formed in such a way that the sides are harder than the base (as by subjecting the sides to a higher heat than the base in the vulcanization); they may be made of raw rubber or of waste rubber from old tires, mixed with S, ZnO, an accelerator such as diphenylguanidine and a lubricant such as paraffin. Various details of manuf. are given.

Rubber cement. THEODORE WHITTELSEY. U. S. 1,793,983, Feb. 24. Rubber latex is used with a solvent such as C_6H_6 and a small quantity of an emulsifying agent such as Na oleate, which facilitates diln. of the cement with water.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 337,460, Aug. 2, 1929. Alkali metal such as Na used in effecting polymerization of diolefins is enclosed in a small perforated container (which may be formed of glass or metal) placed within the reaction vessel. When the small perforated container becomes filled with polymerizate the latter with some assocd. alkali metal is forced out into the main reaction vessel to promote further polymerization of its contents. The process may be carried out in 2 stages and a diluent such as diethylene dioxide may be used.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 338,152, May 14, 1929. Polymerization of diolefins such as butadiene is effected with at least 30% of an inorg. O-contg. acid or an org. deriv. of such an acid (without addn. of any other substance influencing the reaction). Among the substances which may be used are: H_2SO_4, H_3PO_4, benzenesulfonic acid, toluenesulfonic acid, *p*-toluene sulfonylchloride and benzene sulfonylchloride. Products of varying character are obtained by varying the conditions of the reaction, and they may be suitable for adhesives, as *addns. to paints or lacquers, manuf. of threads, films,* molded articles, etc. Several examples with details of procedure are given.

Rubber-like product. JEAN BAER. Swiss 142,456, Jan. 8, 1929. A rubber-like mass is obtained by treating an isoprene halide with alkali or alk. earth polysulfides. In the example, isoprene dibromide is treated with K_2S_x. Cf. *C. A.* **24**, 1545.

Factice. JEAN BAER. Swiss 142,354, to 142,357, June 19, 1928. Addns. to 137,477 (*C. A.* **24**, 4426). Factice sol. in hydrocarbons is prepd. by heating the rubber-like mass from CH_2Cl_2 and a polysulfide soln. with an oil such as rapeseed oil. The CH_2Cl_2 may be replaced by $C_2H_4Br_2$, CH_2Br_2 or CH_2O.

Rubber vulcanization accelerators. ALBERT M. CLIFFORD (to Goodyear Tire & Rubber Co.). U. S. 1,792,819, Feb. 17. As an accelerator, there is used the reaction product of cyclohexylamine and an aldehyde such as aldol, butyraldehyde, crotonaldehyde, heptaldehyde or formaldehyde.

Rubber vulcanization accelerators. LORIN B. SEBRELL and DEXTER N. SHAW (to Goodyear Tire & Rubber Co.). U. S. 1,792,770, Feb. 17. *o*-Tolylamidoxime or other compds. of the general formula $RC(:NOH)NH_2$, in which R represents a benzene group, are used as accelerators.

Rubber vulcanization accelerators. JAN TEPPEMA (to Goodyear Tire & Rubber Co.). U. S. 1,792,780, Feb. 17. Vulcanization with S is effected in the presence of the reaction product of mercaptobenzoxazole and a basic amine such as diphenylguanidine. Cf. *C. A.* **24**, 3135.

Apparatus for vulcanizing lengths or sheets of rubber or rubberized material. HARRY WILLSHAW and WALTER G. GORHAM (to Dunlop Rubber Co., Ltd.). U. S. 1,793,269, Feb. 17. Structural features.

CHEMICAL ABSTRACTS

Vol. 25. **MAY 20, 1931** **No. 10**

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Modern laboratory furniture. CARL G. SCHWALBE. *Chem. Fabrik* **1931**, 111–3.—Improvements in floor and wall coverings, desks, showcases, downward ventilation and waste-water sedimentation are described. J H. MOORE

Simple laboratory autoclave. HAROLD A. CASSAR. *Ind. Eng Chem., Anal. Ed.* **3**, 197–8(1931).—Details are given for making a small app. at a cost of about $20. J. H. MOORE

The removal of traces of oxygen from nitrogen. E. C. KENDALL. *Science* **73**, 394–7(1931). —See *C. A.* **24**, 4428. G. G.

New heating chamber for micro carbon-hydrogen determinations by the method of Pregl. A. VERDINO. *Mikrochemie* **3**, 123–5(1931).—Some difficulty has been encountered with respect to the heating of the PbO_2 to the necessary temp. in the combustion train. The vessel described in this paper consists of a chamber 65 mm. in length and 30 mm. in outside diam. with an opening for the insertion of the combustion tube and 2 other openings for the Cu pieces which serve to heat the capillary restrictions of the $CaCl_2$ tube. The heating chamber is filled with decalin (decahydronaphthalene) b. 190°. A vertical metal tube serves as air cooler for the vapors with an outside mantle of glass into which the condensed liquid overflows when the chamber is heated too strongly. The chamber is heated electrically. W. T. H.

A micro-manometer with convenient reading. A. BETZ. *Messtech.* **7**, 37–9 (1931).—The app. was designed for measuring changes in pressure up to about 200 kg. per sq. m. with a sensitivity of 0.05–0.1 kg. per sq. m. A vertical glass scale is attached to a float in water in a closed vessel so constructed that changes in the water level are increased 9-fold in the tube contg. the float. The scale readings, magnified 20-fold, are projected on a screen. J. H. MOORE

Apparatus for determining coefficients of conductivity of insulating slabs. C. CODEGONE. *Industria* (Milan) **44**, No. 15, 401–3(1930). E. I. S.

Control of the ocular scale of Abbé's butyrorefractometer. K. SZÁHLENDER. *Magyar Gyógyszerészlud. Társaság Értesitoje* **7**, 135–8(1931).—The correction table of D. A. B. 6 cannot be used for controlling and correcting the scale, since the controlling liquid (paraffin) should not be older than 6 months. New correction data should be obtained from the factory when new controlling liquid is bought. Data for freshly bought normal liquid no. 29 show divergences up to 3% from the D. A. B. 6 table. S. S. DE FINÁLY

A tube voltmeter. FRIEDRICH L. HAHN. *Chem. Fabrik* **1931**, 121; cf. *C. A.* **24**, 5185.—The app. was evolved from the Goode app. (*C. A.* **19**, 3389) and resembles the Berl app. (*C. A.* **25**, 235). J. H. MOORE

Improved hydrogen-electrode cell for determination of p_H. W. B. BOLLEN. *Ind. Eng. Chem., Anal. Ed.* **3**, 203–9(1931).—The cell, constructed from usual lab. materials, is widely applicable for rapid and accurate p_H detns. Novel features are (1) a Pyrex-Alundum porous-tip calomel electrode, the porous tip being made by sintering a 100-mesh mixt. of Pyrex glass and Alundum in a glass tube, (2) an H-shaped salt bridge capable of giving sharp, reproducible liquid junctions and (3) a stirrer which centrifugally circulates through the soln. a small const. vol. of H under const. pressure. The stirrer-circulator especially adapts the H electrode to solns. contg. dissolved CO_2 or other gases entering into the H-ion equil. and enables foaming liquids to be handled easily. Satn. of the soln. with H is effected in min. time and the true H-ion equil. quickly attained. The use of voltage-time curves in estg. the true H-ion equil. in solns. where secondary reactions occur is discussed, together with the advantages of the new app. over the bubbling H electrode. Typical data given illustrate the rapidity (1–2 mins. for equilibrium), accuracy (values to within 1 mv.) and versatility of the app. EDWARD B. SANIGAR

The Stroboglow. W. ENDRES BAHLS AND D. D. KNOWLES. *Elec. J.* **28**, 250–3 (1931).—This instrument is a rugged portable stroboscope. The true behavior of the various parts of a machine having periodic motion can usually be learned only when the machine is in normal running operation. The Stroboglow is designed to permit the study of moving parts in out-of-the-way places. It is portable, self-contained, and is packed in two large-size suitcases. There are no moving parts and expert service is unnecessary. It has a broad speed range. The requisites of the ideal stroboscope are summarized as: (1) ruggedness, (2) portability, (3) simple and effective control of large currents, (4) exceedingly short duration of light pulsations; (5) very intense light pulsations, (6) minimum of moving parts, (7) simplicity of operation and (8) accuracy of timing light flashes. The Stroboglow, it is claimed, fulfils these requirements. It consists essentially of the oscillator or interrupter and the light unit. The heat of the light unit is the power grid-glow tube. The instrument is illustrated, and the oscillator circuit shown in a diagram. Various applications are indicated. W. H. BOYNTON

Color pyrometry. GERHARD NAESER. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* **12**, 299–316(1930).—An instrument has been constructed for selecting 2 widely sepd. spectral colors by means of a double prism. Light from an unknown source is then compared with light from a Pt strip by adjusting intensities on a half-shadow field. The combination of red (0.65μ) and green (0.53μ) was found to be the most sensitive combination for several different observers, the max. error amounting to 4°. The instrument could also be used as an intensity pyrometer, and the const. in Wien's formula was measured and found to be 1.4235 cm./degree in red and 1.4179 cm./degree in green. On comparison with Pt, W and oxidized Fe, it was found that the instrument registered 60° low for Pt, 20° low for W and very nearly correct on Fe. Elimination of the comparison lamp was found to be possible, but the max. error was somewhat larger. H. C. D.

Determination of color with F. Herzfeld-Hoffmann's polarization-photometer. I. B. MINTZ AND A. K. KARTASHOV. *Nauk. Zapiski z. Tzukrovoi Prom.* **10**, 257–67(1930) —The app. and its use are described. V. E. BAIKOW

Material requirements and material testing for heavy-duty chemical apparatus. ERNST FRANKE. *Chem. Fabrik* **1931**, 133–5.—A brief review of the demands placed on construction materials in regard to aging, embrittlement, durability at high temps., etc., with remarks on methods of taking test pieces and making tests for phys. properties. J. H. MOORE

The classification of wet materials. C. H. S. TUPHOLME. *Mech. World* **88**, 228 331(1930).—An outline of some of the more prominent devices for screening wet materials. E. I. S.

Chemical apparatus and their relation to the provisions of the Berufsgenossenschaft of the chemical industry and to the steam-vessel regulations. SCHEFFEL. *Chem Fabrik* **1931**, 109–11.—A discussion is given of the lack of uniformity of regulations for steam vessels in the German states, the desirability of having national regulations, the effect of new materials and specifications and the use of autogenous and elec. welding. J. H. MOORE

Simple calculations for reciprocating compressors. JOS. IMMERSCHITT. *Apparatebau* **43**, 62–5(1931).—A table of values is given to simplify the selection of the proper size of compressor for gases. An example is worked out to show how the table is to be used. M. C. ROGERS

Transfer of heat in recuperators. I. E. TERRES AND W. BESECKS. *Heat Treating and Forging* **16**, 1573–6, 1579(1930).—See *C. A.* **23**, 3378. J. BALOZIAN

Furnace-door arches and air-cooled walls. WM. C. REIFUSS. *Heat Treating and Forging* **16**, 1571–2(1930).—The construction of a double furnace (for heating for steam hammers) is briefly described, a party wall with an air passage sepg. the 2 furnaces. This method of construction conserves space and gives very satisfactory results. A method of constructing furnace-door arches with tongued and grooved radial blocks is briefly indicated. J. BALOZIAN

A precision cryostat with automatic temperature regulation. R. B. SCOTT AND F. G. BRICKWEDDE. *Bur. Standards J. Research* **6**, 401–10(1931).—A detailed description is given of the construction and operation of an app. that will, by means of a photo-elec.-cell thermo-regulator, automatically hold any desired temp. between 0 and −170° const. to 0.001°. The temp. is easily adjusted, and the degree of refrigeration is controlled by varying the gas pressure in the double-walled bath which is surrounded by a Dewar flask contg. liquid air. J. H. MOORE

Introducing alkali or alkaline earth metals or O into sealed glass vessels (Austrian

pat. 121,033) **4.** Purifying inert gases in electric-discharge tubes, etc. (Austrian pat. 121,056) **4.** Stoneware in the chemical industry (WEINREB) **19.**

Separating dust, etc., from air, etc. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG. Ger. 518,087, June 19, 1927. See Brit. 292,479 (*C. A.* **23**, 1452).

Device for separating dust from air by baffling and centrifugal action. HECTOR RABEZZANA (to A C Spark Plug Co.). U. S. 1,795,888, March 10. Structural features.

Baffle-screen device for removing dust from air, etc. GLENN P. HEATH. U. S. 1,796,946, March 17. Structural features.

Centrifugal separator. AKTIEBOLAGET SEPARATOR. Brit. 339,566, March 4, 1929. In an app. for sepg. liquids from solids, a layer or stream of Hg serves for a carrier of the solids. Various details of construction and operation are described.

Gas separator suitable for separating liquid particles from steam, etc. GRANT D. BRADSHAW and RALPH N. ROBERTSON (to Blaw-Knox Co.). U. S. 1,796,435, March 17. Structural features.

Separator for oil and water, etc. DAVID SAMIRAN and PHILLIPS MELVILLE. Ger. 518,149, Jan. 1, 1929. See Brit. 322,654 (*C. A.* **24**, 2643).

Calorimeter. HERMANN SANDVOSS. Ger. 515,712, Nov. 20, 1926. Addn. to 491,954 (*C. A.* **24**, 3402).

Pyrometer (suitable for indicating the failure of a railway or other signal lamp). C. W. COOKE. Brit. 339,200, June 11, 1929. When a lamp flame is burning properly, the expansion of metal strips in the device serves to complete an indicator circuit which is broken when the flame is extinguished or becomes too low. Various details of construction are described.

Apparatus and method for reducing the temperature of air by dehydration and saturation. WALTER L. FLEISHER (to Cooling & Air Conditioning Corp.). U. S. reissue 17,998, March 10. Reissue of original pat. No. 1,749,763 (*C. A.* **24**, 2012).

Bimetallic strip thermometer suitable for ovens. THERMOSTATICS, LTD., O. MILLER and F. MILLER. Brit. 339,397, Sept. 30, 1929.

Automatic level regulator for liquid containers, etc. WM. MONCHEN. Ger. 515,677, Feb. 13, 1930.

Drying apparatus for pasty or gelatinous materials, especially pigments. FRITZ HAAS. Ger. 518,379, Aug. 3, 1929.

Cascading apparatus suitable for drying crystals, cereals, etc. REGINALD V. FARNHAM. U. S. 1,796,324, March 17. Structural details of an app. for drying with gaseous media.

Automatic control system for apparatus for drying materials by recirculated air. GEORGE B. BAILEY. U. S. 1,795,418, March 10. Structural features and details of a thermostatic control system are described.

Rotary drum for cooling or drying chemicals or raw materials. BERNHARD SÄGEBARTH. Ger. 515,834, July 28, 1927.

Tube-cleaning device for rotary-tube drying apparatus. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 518,380, Dec. 6, 1929.

Means for inspecting the interior of evaporators. HANS WOLLENBERG. Ger. 518,314, Mar. 19, 1929.

Röntgen-ray apparatus. SIEMENS-REINIGER-VEIFA GES. FÜR MEDIZINISCHE TECHNIK. Brit. 339,212, March 1, 1929. Structural features.

Röntgen-ray apparatus. C. H. F. MÜLLER A.-G. Brit. 339,215, March 9, 1929. Structural features.

X-ray tubes. SENDLINGER OPTISCHE GLASWERKE G. M. B. H. (Fritz Eckert, inventor). Ger. 518,172, Aug. 14, 1923 Hot-cathode x-ray tubes are made of glass contg. up to 8% of rare earths, with or without TiO_2 and (or) V_2O_5. A suitable compn. is SiO_2 70, Al_2O_3 2, MgO 3, Na_2O 20 and Ce_2O_3 or other rare earth 5%.

Electric-discharge lamps. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN (to General Electric Co., Ltd.). Brit. 338,844, May 2, 1930. Some modifications of construction are described, relating to devices such as those of Brit. 315,391 (*C. A.* **24**, 1550).

Electron-emission device. JOHN W. MARDEN (to Westinghouse Lamp Co.). U. S. 1,795,730, March 10. Various structural details of sealed devices contg. alkali metal. Cf. *C. A.* **25**, 622.

Electron-emitting cathodes of discharge devices. GRAMOPHONE CO., LTD., and G. B. BAKER. Brit. 339,451, Nov. 14, 1929. A refractory core or oxide-coated filament is coated with a substance which on heating in the absence of appreciable O leaves a residue contg. the oxide of an electron-emitting metal, such as Cs tartrate or Ba tartrate, and free C. Various details of manuf. are described.

Electron-emitting cathodes for discharge tubes. GRAMOPHONE CO., LTD., W. F TEDHAM and F. ELLINGTON. Brit. 339,057, Oct. 16, 1929. Cathodes are formed with a core or layer of Al provided with an oxidized surface having on it an electron-emitting coating which may comprise Cs, Ba or other metal deposited electrolytically or otherwise on the Al (which may have been preliminarily oxidized by making it anode in a dil. chromic acid soln.). If desired the oxidized Al may be carried on a core of other material such as W or kaolin.

Rotary-hearth furnace. ERNEST G. DE CORIOLIS, JESSE R. MOSER and ARNOLD L. LARSEN (to Surface Combustion Corp.). U. S. 1,796,144, March 10.

Movable-hearth furnace with automatic dumping mechanism suitable for heat treatments. JOHN F. BAKER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,921, March 10. Structural features.

A two-chamber furnace with movable roof. YA. A. FRANTZUZ. Russ. appl. 56,402, Oct. 15, 1929.

Continuous-chain furnace. SOC. ANON. DES APPAREILS DE MANUTENTION ET FOURSTEIN. Fr. 695,230, Aug. 30, 1929.

Refractory furnace or retort setting. SOUTH METROPOLITAN GAS CO. and W. T. SEACH. Brit. 339,268, Sept. 3, 1929.

Inclined-grate furnace. ERNST VÖLCKER. Ger. 518,429, July 15, 1928. Means for advancing the fuel is described.

Step grate for low-grade or pulverulent fuel. FRANZ HOLZINGER. Austrian 121,290, Sept. 15, 1930.

Traveling grate. HERMANN KRÖNAUER. Ger. 518,430, Oct. 27, 1929.

Oil burner (open-dish type). OTTO SCHIEDEK and BERTHOLD OSTER. Ger 518,425, Sept. 25, 1929 and 518,426, April 24, 1929.

Regenerative gas furnace. FRIEDRICH SIEMENS A.-G. Fr. 37,175, July 2, 1929 Addn. to 591,158.

Gas burner. JAY M. AXTELL. U. S. 1,796,915, March 17.

Gas burner suitable for ovens. A. H. CLUTTERBUCK and S. W. HUMPHREY Brit. 338,806, Jan. 30, 1930.

Diaphragm-controlled gas-valves for heating systems. PAUL F. SHIVERS (to Minneapolis-Honeywell Regulator Co.). U. S. 1,796,544, March 17. Structural features.

Fuel-distributing means for annular or chamber kilns. MICHAEL BOHN. Austrian 120,993, Aug. 15, 1930.

Movable feeding device for annealing ovens. A.-G. BROWN, BOVERI & CIE Ger. 518,218, Jan. 11, 1927.

Rotary-tube oven for treating cork with hot gases. NICOLO MASSA. Austrian 121,253, Sept. 15, 1930.

Pressure-operated valve-actuating means for blast heaters, etc. ZIMMERMANN & JANSEN G. M. B. H. Ger. 518,413, Dec. 17, 1929.

Air heaters. MAX & ERNST HARTMANN. Ger. 518,174, May 21, 1927. Failure of the air supply automatically operates dilg. means for the heating gases.

Air heater for drying apparatus. BRUNO WAGNER. Ger. 518,162, Jan. 20, 1928.

Heat-exchange apparatus. I. G. FARBENIND. A.-G. Brit. 338,818, Feb. 13, 1930. An app. for heat exchange between 2 fluids comprises a composite block formed of plates of good thermal cond. such as Cu or Al alternating with plates of low-heat cond. such as asbestos or mica. The fluids traverse alternate borings in the block, and the layers of low cond. reduce the heat loss in the direction of flow of the fluids.

Heat-exchange apparatus suitable for heating air by hot gases. WM. A. JONES (to Babcock & Wilcox Co.). U. S. 1,796,944, March 17. Structural features.

Heat-exchange apparatus suitable for heating air by hot gases. ISAAC HARTER (to Babcock & Wilcox Co.). U. S. 1,796,945, March 17. Structural features.

Heat-exchange apparatus suitable for drying, evaporating, melting, etc. OTTO ENGLER (to Schmidt'sche Heissdampf-G. m. b. H.). U. S. 1,796,707, March 17. Structural features.

Heat-exchange apparatus (suitable for heating water by gas burners). FRANK W. OFELDT. U. S. 1,796,662, March 17. Structural features.

Tubular heat-transfer apparatus suitable for use as an auxiliary water heater. WALTER A. DALEY (to Bell & Gossett Co.). U. S. 1,796,509, March 17. Structural features.

Electric water heater. T. DALL. Brit. 339,475, Nov. 26, 1929.

Enameled boilers and other vessels with heating or cooling coils in their walls. RICHARD SAMESREUTHER, BUTZBACH HESSEN and GEORG KRÄNZLEIN (one-half each to I. G. Farbenind. A.-G. and Samesreuther & Co. G. m. b. H.). U. S. 1,796,123, March 10. Plane or curved metal sheets which do not possess the qualities of ingot iron may be formed into heating or cooling elements by pressing a support of soft metal (skelp), as for instance, Cu, Pb or Al, between the tubes and the surface of the metal plate or wall and then welding the exposed parts of the tubes by one of the usual methods so as to unite them closely. Before carrying out the welding operation, the coils of the tubes may be pressed upon the support of soft metal by means of solid metal clamps, which on their part are firmly united with the plane or curved surface of the metal by a cam device, flanges or other auxiliary means. Advantageously, the clamps are in this case united with the tubes by welding. In this manner it is possible to prepare from iron silicide, cast iron, Al, Ag or Ni steels app., as for instance pans or boilers, which can be indirectly heated or cooled.

Apparatus for mixing added materials with flowing streams of liquid. J. A. PICKARD. Brit. 338,945, Aug. 1, 1929. Various details of construction are described of an app. suitable for supplying "filter aid" to beer passing to a filter, etc.

Receptacle and outlet valve for compressed or liquefied gases. CHARLES W. JOHNSTON (to Virginia Smelting Co.). U. S. 1,795,560, March 10.

Apparatus for saturating liquids with gases. GEORGE F. SUGDEN. Ger. 518,288, Dec. 19, 1924. See U. S. 1,561,036 (*C. A.* **20**, 2).

Bell cap for use in apparatus such as gas and liquid contact towers. WM. J. SEELAND (to Standard Oil Development Co.). U. S. 1,796,256, March 10.

Bubble tower for gas and liquid contact operations such as fractionation or absorption. CLIVE M. ALEXANDER. U. S. 1,796,135, March 10.

Apparatus for purifying gases, such as steam, carrying liquid particles. GRANT D. BRADSHAW (to Blaw-Knox Co.). U. S. 1,796,436, March 17. Structural features.

Apparatus for purifying air by spray treatments. CARL J. SCHOBRONE. U. S. 1,796,405, March 17. Structural features.

Gas purifier suitable for treating steam. HARRY E. BOYRIE (to Blaw-Knox Co.). U. S. 1,796,434, March 17. Structural features.

Gas washer. P. J. ROBINSON. Brit. 338,527, May 18, 1929. Structural features of an app. with an alloy steel shell or a shell made of flanged sections sheathed with Pb.

Measuring tube for gas-analyzing apparatus. H. DUBOVITZ. Hung. 100,695, Dec. 6, 1929. Analysis can be made more accurately by the use of measuring tubes with diminishing diameters, *e. g.*, conical forms.

Apparatus for estimating gas concentrations. SIEMENS & HALSKE A.-G. (Heinz Grüss, inventor). Ger. 517,112, Jan. 13, 1929. Addn. to 501,514 (*C. A.* **24**, 4876). The method depends on variation of the elec. cond. and is specially applicable to CO_2.

Surface condenser. FRANCOIS X. J. A. DELAS. U. S. 1,796,510, March 17.

Condenser suitable for use with steam. JOHN F. GRACE (to Worthington Pump and Machinery Corp.). U. S. 1,796,708, March 17. Structural features.

Catalytic apparatus. COMPAGNIE INTERNATIONALE POUR LA FABRICATION DES

ESSENCES ET PÉTROLES. Fr. 37,265, Mar. 16, 1929. Addn. to 673,683 (*C. A.* **24**, 2514–5). In the treatment of gases and vapors with purifying or catalytic agents a vessel of annular cross section is used having the catalytic or purifying material between 2 false bottoms, the spaces between the false bottoms and the bottoms serving, resp., as admission chamber for the gases to be treated and exit chamber for the treated gases. Cf. *C. A.* **25**, 1125.

Apparatus for carrying out physical and chemical reactions. I. G. FARBENIND A.-G. (Hans Bähr, inventor). Ger. 514,500, Sept. 10, 1929. Addn. to 503,993 (*C. A.* **24**, 5541). The chains mentioned in Ger. 503,993 for circulating the reacting substances pass through tubes of various lengths.

Apparatus for testing gases or liquids by thermal conductivity measurements. CHARLES ENGELHARD, INC. Ger. 518,177, Oct. 18, 1927. See Brit. 288,908 (*C. A.* **23**, 551).

Apparatus for converting concentrated solutions into granulated solids. I. G. FARBENIND. A.-G. Fr. 37,354, Aug. 19, 1929. Addn. to 673,135 (*C. A.* **24**, 2340). The app. consists of a rotating plate beneath a circular distributor provided with notches so as to form a circular opening between the two.

Apparatus for the distillation of solids and liquids. HENRY DUPUY. Fr. 37,244, July 23, 1929. Addn. to 552,349.

Filling for reaction and washing towers, etc. ERNST BERL. U. S. 1,796,501, March 17. A filling device is formed from a circular blank of any suitable material, folded in a crosswise reversed manner to resemble a riding saddle, the height and breadth being substantially equal.

Apparatus for liquefying chlorine by compression. KREBS & CO. G. M. B. H. (Wilhelm Lehmann, inventor). Ger. 515,929, Oct. 11, 1929.

High-speed mixer for making emulsions, effecting chemical reactions, etc. GASTON S. P. DE BÉTHUNE. Ger. 518,200, Mar. 14, 1928. See Brit. 292,592 (*C. A.* **23**, 1314).

Pump and high-speed emulsifier system for making emulsions such as those of bituminous materials. G. C. HURRELL and ROAD DEVELOPMENT CO., LTD. Brit 338,496, Aug. 13, 1929. Various details of construction and procedure are described

Acid-resistant apparatus. H. FRISCHER. Brit. 339,032, Sept. 26, 1929. Vessels or appl resistant to HNO_3 comprise an Al alloy contg. Mg, Si, etc., where exposed to acid liquid and a more resistant alloy such as Fe-Si or Cr-Ni alloy where exposed to the fumes.

Apparatus (with an immersed propeller) for mixing acids, etc. MASCHINENFABRIK AUGSBURG-NÜRNBERG A.-G. Brit. 338,440, Sept. 6, 1929. Various structural details are described.

Float for determination of the specific gravity of accumulator electrolytes. TUDOR ACCUMULATOR, LTD. Hung. 101,225, Feb. 4, 1930 "Kunstwachs" is mixed with $BaSO_4$ to form balls having different sp. gravities. These balls are not influenced by gas bubbles as are those made of natural wax.

Apparatus for casting films. RADEBEULER MASCHINENFABRIK AUGUST KOEBIG G. M. B. H. Ger. 518,037, Dec. 23, 1928.

Apparatus for making films from masses which harden in the air. RICHARD MARIOTTI. Austrian 121,598, Oct. 15, 1930.

Sheet metal articles coated with corrosion-resisting material which can be hardened by vulcanization or other treatment. P. PICK. Brit. 339,320, July 23, 1928. Various details of manuf. are given, mainly of mech. character, for making funnels, drums for holding chemicals, etc.

Annealing pot. ÖSTERREICHISCHE SIEMENS-SCHUCKERT-WERKE. (Erwin Häuser, inventor). Austrian 120,850, Aug. 15, 1930.

Acetylene generator. AUTOGENWERK SIRIUS G. M. B. H. Ger. 518,336, Feb. 6, 1930. Addn. to 474,145 (*C. A.* **23**, 2855).

Apparatus for distilling water by heat from the exhaust of an internal-combustion engine. H. J. WILSON. Brit. 338,953, Aug. 27, 1929. Structural features.

Mercury boiler. B. P. COULSON (to British Thomson-Houston Co., Ltd.). Brit 339,237, June 14, 1929.

Aluminum-coated steel soot-blower tubes for boilers, etc. WHITTEMORE, HULBERT, WHITTEMORE & BELKNAP and H. G. C. FAIRWEATHER. Brit. 338,867, Aug. 21, 1929. A tubular steel core is coated on both sides with a thin layer of Al which is adapted to alloy with the steel when the tube is placed within the boiler and subjected to heat. Various details of manuf. are described.

Safety gas valve for cutting off gas on flame extinguishment. LOUIS KREUTZKAMP. U. S. 1,796,998, March 17. Structural features.

Thermostatic electric switch. HILTON I. JONES. U. S. 1,795,400, March 10.

Thermostatic electric switch (containing mercury). THEODORE M. BURKHOLDER (to Engineering Products Corp.). U. S. 1,795,831, March 10. Structural features.

Thermostatic control device for electric circuits. EDMUND SCHERER. U. S. 1,796,726, March 17. Structural features.

Thermostatic control device for electric circuits. HARRY L. BRADLEY and GUSTAV O. WILMS (Wilms to Lynde Bradley). U. S. 1,797,126, March 17. Structural features.

Snap-action thermostatic device suitable for controlling electric circuits. ADOLPH A. THOMAS. U. S. 1,795,907, March 10. Structural features.

Thermostatic device suitable for controlling the flow of steam, etc. GLENN H. SEELY (to Bristol Co.). U. S. 1,796,124, March 10. Structural features.

Thermostatic control device suitable for control of fluid fuel supply to burners. EDWARD L. FONSECA (to Wilcolator Co.). U. S. 1,796,196, March 10. Structural features.

Thermostatic valve suitable for controlling the flow of heating fluids. FREDERICK W. JAEGER. U. S. 1,795,860, March 10.

Thermostatic valve. H. N. ROBINSON, G. W. WORTLEY and R. & A. MAIN, LTD. Brit. 339,341, Sept. 4, 1929.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Chemists, chemistry and people. E. T. STERNE. *Can. Chem. Met.* **15**, 71–3 (1931).—An address. W. H. BOYNTON

Eduard Cramer. HIRSCH. *Z. angew. Chem.* **44**, 230–1(1931).—Obituary. E. H.

Fritz Pregl. H. LIEB. *Mikrochemie* **3**, 105–16(1931).—Obituary. W. T. H.

Edgar Fahs Smith: Provost, chemist, friend. CHARLES F. THWING. *Science* **73**, 331–3(1931). E. H.

In memoriam—Henry Leffman—1847-1930. IVOR GRIFFITH. *Am. J. Pharm.* **103**, 118–9(1931). W. G. GAESSLER

Dr. Henry Leffman—life story. CHARLES H. LAWALL. *Am. J. Pharm.* **103**, 113–17(1931).—Biography with portrait. W. G. GAESSLER

The scientific work of P. A. Levene. OTTO FOLIN. *Chem. Bull.* **18**, 99–101, 121 (1931). E. H.

Rudolf Dietz on his seventieth birthday. F. FOERSTER. *Z. angew. Chem.* **44**, 229–30(1931).—A portrait is included. E. H.

The work of Marcelin Berthelot and his influence on modern chemistry. JEAN PEPIN-LEHALLEUR. *Ann. soc. pharm. chim. Sao Paulo* **2**, 38–44(1931). E. H.

Lord Melchett and his accomplishments. JAROSLAV JELÍNEK. *Chem. Listy* **25**, 41–7(1931). FRANK MARESH

The achievements of Josef Schneider. E. TEYKOVSKÝ. *Chem. Listy* **25**, 49–53 (1931).—A brief biography is followed by a bibliography of Schneider's contributions covering all branches of chemistry. FRANK MARESH

Some scientific-instrument makers of the eighteenth century. I, II. ROBERT S. WHIPPLE. *J. Sci. Instruments* **7**, 241–53, 273–81(1930); *Science* **72**, 208–13. E. J. C.

Recent advances in science: Physical chemistry. R. K. SCHOFIELD. *Science Progress* **25**, 398–403(1931).—Recent work on contact catalysis is reviewed. J. S. H.

Discoveries and investigations in the older chemistry up to the phlogiston theory of Stahl. HOFFMAN. *Sitzb. preuss. Akad. Wiss.* **1931**, lviii–lxvi. E. H.

The activity of the general chemistry laboratory [at the University of Gand, Belgium]. F. SWARTS. *Bull. soc. chim. Belg.* **39**, 444–53(1930).—A review dealing more especially with work on org. fluorides. A. L. HENNE

What conclusions must classical physics and chemistry draw from the principle of greatest simplicity? L. ZEHNDER. *Z. Physik* **63**, 706–12(1930).—Ten postulates are given based on the principle of greatest simplicity. Classical physics must either obey these or be wrong in its fundamental suppositions. B. C. A.

Multiple preparation of hydrogen electrodes. V. RICHARD DAMERELL. *J. Chem. Education* **7**, 1664–7(1930).—A rubber stopper was bored to take 6 electrodes, 2 reference electrodes and a H-inlet tube. This was used to stopper all beakers in which the operations required by Clark's method took place. Platinization is best at 2.5 v. It is not

necessary to bubble the H gas directly on the foil, for Pt black readily absorbs the gas in soln. ANN NICHOLSON HIRD

The equilibrium between matter and energy. I. PETRYANOV. *J. Russ. Phys.-Chem. Soc.*, Phys. Pt. **62**, 241–5(1930).—The conditions of equil. between matter and energy were investigated. The following equation was derived: $W_T = RT\ln K_T - ((M_2 - M_1)c^2/3)$, where W_T is total work done, M_1 and M_2 are mol. wts. of true gases, c is the velocity of light and $K_T = -c_2/c_1$, where c_1 and c_2 are the concns. of gases in the system. V. VESSELOVSKY

The molecular structure of triatomic gases. II. H_2O, H_2S and N_2O. P. C. MAHANTI. *Physik. Z.* **32**, 108–10(1931); cf. *C. A.* **24**, 276.—Data on dipole moments, Raman spectrum, and infra-red absorption indicate that H_2S has a triangular structure like H_2O, while N_2O has a symmetrical linear form. T. H. CHILTON

Recent advances in the interferometric determination of the form of molecules. H. MARK. *Z. angew. Chem.* **44**, 125–30(1931).—Recent significant developments in the exptl. methods and the theory of the x-ray interferometric detn. of the structure of crystals are summarized. These have been of particular value in elucidating the structure of the more complex and less sym. org. mols. Recent applications of x-ray methods and of streams of electrons to the detn. of the structure of mols. in gases are discussed. The results of numerous x-ray interferometric studies of simple CH_4 derivs are correlated to show the extent to which they substantiate the regular tetrahedral symmetry of CH_4 demanded by classical theory. R. H. LOMBARD

Dielectric constants of liquefied gases. J. C. MCLENNAN, R. C. JACOBSEN AND J. O. WILHELM. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 37–46(1930).—The dielec. consts. of liquid N_2, A, CH_4 and N_2O were detd. in a specially constructed flask and at various temps. at and above their f. ps. The dielec. consts. referred to vacuum and at selected temps. are as follows: N_2 at 70.5°K. 1.478, A at 87.1°K. 1.520, CH_4 at 106.7°K. 1.694 and N_2O at 70.8°K. 2.023 J. W. SHIPLEY

The dielectric constant of supercooled sulfur and several sulfur solutions. STEFAN ROSENTAL. *Z. Physik* **66**, 652–6(1930).—For the examn. of liquids that attack metal plates, a glass condenser was made, consisting of concentric glass vessels. On the inside surface of the inner vessel was a sheet of Ag; on the outside of the app. a sheet of Cu The liquid was admitted between the glass vessels through connecting tubes. The dielec. const. of S was 3.720 ± 0.003 at 130°. Values were obtained from 135° to 95° At 107° a sharp change was observed. Liquid S followed the law of Clausius-Mossotti (polarization, p = const.); $p = 0.26280 \pm 0.00006$. This law was also followed by S in C_6H_6 and CS_2. L. P. HALL

The dielectric constant of liquid bromine. DOBIESLAW DOBORZYŃSKI. *Z. Physik* **66**, 657–68; *Bull. intern. accad. polonaise* **34**, 97–111(1930); cf. *C. A.* **22**, 1897.—With the condenser described in the preceding abstr., the dielec. const. of Br was measured from 0° to 53.8°; 3.334 ± 0.010 was found at the lower, and 2.964 at the higher, temp Polarization was a function of temp. Thus, Br followed the Debye theory for dipoles and the dipolar moment was calcd. as 0.49×10^{-18} e. s. u. L. P. HALL

Thermodynamic properties of dichlorodifluoromethane, a new refrigerant. I. Equation of state of superheated vapor. RALPH M. BUFFINGTON AND W. K. GILKEY *Ind. Eng. Chem.* **23**, 254–6(1931).—The consts. of a Beattie-Bridgeman equation of state for superheated CCl_2F_2 vapor were detd. from measurements of isometrics between vols. of 1.4 and 4.2 l. per mol. In this region the isometrics are straight. The final equation is $p = [RT(V + B)/V^2] - (A/V^2)$, where $A = 23.7[1 - (0.305/V)]$ and $B = 0.59[1 - (0.622/V)]$. The units are atms., degrees abs. and l. per g.-mol. The equation fits the observed data with an av. error of 0.5%. A. L. H.

The most important methods for determining surface tension. E. HIEDEMANN *Z. physik. chem. Unterricht* **44**, 1–12(1931).—The various methods of surface-tension measurement are discussed from the standpoint of their adaptability as student expts in physics labs. Four methods are suggested: (1) the torsion-balance method of Lenard (cf. *C. A.* **18**, 2827); (2) capillary-rise method in a specially designed simple app.; (3) a differential capillary-rise method using an app. in which 2 capillary tubes and a tube (*a*) of wider bore are attached to a horizontal tube and fitted with a close-fitting thermometer which serves as a piston to regulate the height of the liquid in the capillary tubes; (4) a compensation method of Ferguson and Dowson (cf. *C. A.* **16**, 2436). Bibliography. E. R. SCHIERZ

The density of liquids. OSCAR DE SOUZA VIEIRA. *Rev. brasil. chim.* **1**, 92–6 (1929).—A study of the methods of operating the hydrostatic balance in the detn. of the d. of liquids. JOHN M. LADINO

The critical anisotropic point of ferromagnetic crystals. N. S. AKULOV. *Physik.*

Z. **32**, 107–8(1931).—The relative change of elec. resistance of a ferromagnetic crystal under the influence of magnetization is expressed by an equation of the same form as that previously given for the change in phys. properties (*C. A.* **24**, 2345). The following law is deduced: If 2 curves of the relative change of elec. resistance *vs.* magnetization, derived for 2 different angles between the magnetization vector and chief axis of the crystal, intersect, then curves for any angles must also pass through this point. An example is given from data of Webster (*C. A.* **21**, 204, 1748). T. H. CHILTON

Translation-gliding in crystals of the sodium chloride structural type. M. J. BUERGER. *Am. Mineral.* **15**, 174–87, 226–38(1930); cf. *C. A.* **24**, 4680.—For crystals of NaCl-like structure, the translation direction, *t*, is detd. by the densest rows of like-charged ions. The translation plane, *T*, is a function both of ion-radius ratio and of the polarizabilities of the constituent ions. Translation along (001) is assocd. with high polarizabilities, translation along (110) with low polarizabilities; with intermediate values both (001) and (110) may function as translation-gliding planes under favorable conditions of load. If the original lattice coördinates of the geometrical crystal structure theory are retained, it is found that translation direction, unit translation, direction of closest equiv. lattice points and direction of closest like charges are identical. The correlation, with minor modifications, extends to other crystals such as magnesite and other carbonates, barite, fluorite, anhydrite. It is pointed out that the translation direction is sp. for a given structural type because the translation direction has the structural character alignment of closest like leptons for all leptons in the structure. An adequate mechanistic explanation of the gliding direction is presented on the assumption that the leptons are individually charged and thus have the character of ions. The actual translation direction is the one resulting in a min. loss of cohesion.
A. M. BRANT

The mechanism of activation of thoriated tungsten and molybdenum. A. GEHRTS. *Z. tech. Physik* **12**, 66–71(1931).— A math. treatment. The mechanism derived on the assumption of Th migration by slip along the crystal surfaces to the surface of W and Mo wires agrees with the exptl. results. The grain-size-diminishing action of thoria in wires may be due to adsorption and migration of Th on the crystal surfaces. A. F.

Addition centers as coördination centers. The crystal structure of veronal. EDUARD HERTEL. *Z. physik. Chem.*, Abt. B, **11**, 279–90(1930).—The crystal structure of veronal, 5,5-diethylbarbituric acid, was detd. crystallographically and roentgenographically. Crystals, m. 191°, d. 1.220, formed by slow growth from aq. soln., were rhombic-bipyramidal, with axial ratios $a:b:c = 0.491:1:0.688$, translation group I_o', space group V_h^{17}, 4 mols. forming the elementary group. Models are depicted. The arrangement of the mols. is attributed to secondary valences. L. P. HALL

Growth and solution of nonpolar crystals. I. N STRANSKI *Z. physik. Chem.*, Abt. B, **11**, 342–9(1930); cf. *C. A.* **22**, 4289. —Soln of homeopolar crystals begins at the corners and edges and growth occurs more easily at the face. Metals in electrolytes, however, grow from the corners. Since homeopolar crystals present more active centers than heteropolar, they should be more effective catalytically. L. P. HALL

Explanation of the electrocapillary Becquerel-phenomenon. A correction. H. FREUNDLICH AND K. SÖLLNER. *Z. physik. Chem.*, Abt. A, **152**, 313–4(1931); cf. *C. A.* **23**, 4394.—The only condition necessary for the sepn. of metal in the Becquerel phenomenon is a pos. value for the decompn. potential, with the convention of a circular current going in one direction through the salt soln., in the other through the metallically conducting membrane. W. W.

Method of obtaining a single crystal of aluminum of any desired crystallographic orientation. T. SANO. *Mem. Coll. Sci. Kyoto Imp. Univ* **13A**, 307–9(1930).—An Al crystal of any desired orientation can be obtained by bringing another crystal into contact with molten Al and lowering the temp very slowly. B. C. A.

Crystal structure of metallic lanthanum. J. C. MCLENNAN AND R. W. MCKAY. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 33–5(1930).—The x-ray spectrum of powdered La was examd. and La found to crystallize in the hexagonal system. The coördinates of the atoms referred to hexagonal axes are $1/3$, $2/3$, $1/4$ and $2/3$, $1/3$, $3/4$. The side of the unit cell is 3.72 A. U. and the axial ratio is 1.63. This arrangement is the same as that of the hexagonal close packing of spheres. J. W. SHIPLEY

Crystal structure of uranium. J. C. MCLENNAN AND R. W. MCKAY. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 1–2(1930).—An x-ray analysis of the crystal structure of metallic U was made by the powder method. The calcd. spacings are for a body-centered cubic arrangement with the side of the unit cell equal to 343×10^{-8} cm. The lines corresponding to the 222 and 004 planes were not observed. Calcd. from the data obtained the d. is 19.6. J. W. SHIPLEY

New forms of crystalline ice. N. ALTBERG AND W. TROSCHIN. *Naturwissenschaften* **19**, 162–4(1931).—In the Kungur caverns (Ural mountains) natural temp. and satn. conditions are such that the growth of large ice crystals (up to 50 cm. in size) is promoted. A few photographs of specimen are presented. B. J. C. VAN DER HOEVEN

Structure of silicon tetrafluoride. G. NATTA. *Gazz. chim. ital.* **60**, 911–22(1930).—A survey of the literature shows that the lattice structures of very few binary compds. of the AB_4 type have been studied by x-rays. It was of interest therefore to exam. compds. of this type, particularly those with a non-ionic structure. The form and symmetry of the cryst. lattice of the latter depend, to a greater degree than for ionic compds., upon the form and symmetry of the individual mol., which maintains its structural unity and behaves as a fundamental constructive element of the cryst. edifice, like the single ions of ionic compds. The present paper deals only with SiF_4, but is part of a more extended series of expts. on the halides of C, Si and Ti. Most of them give excellent x-ray photographs, all of which show the cubic or tetragonal system. SiF_4 has the simplest structure. Since most of the halides have a very low m. p., the app. already used in examg. liquids and gases was again employed (cf. *C. A.* **24**, 4973). Pure SiF_4 was prepd. by freezing out at —60° the HF from the gas evolved from a mixt. of K_2SiF_6, Al silicate and concd. H_2SO_4. The SiF_4 was then liquefied by liquid air. The powder method was used for the x-ray examn. The lattice of the Si atoms in SiF_4 is body-centered cubic. The elementary cell contains 2 mols., with $a = 5.41 \pm 0.01$ A. U. and $v = 158 \times 10^{-24}$ cc. at —170°. The d. is 2.17. SiF_4 is not an ionic compd., and it possesses a "mol. lattice." It belongs to the O^2 spatial group. The position of the atoms in the cell is defined by the coördinates:

$$\begin{array}{l} \text{F } u\,u\,u,\ u\,\bar{u}\,\bar{u},\ \bar{u}\,u\,\bar{u},\ \bar{u}\,\bar{u}\,u. \\ 1/2 + u\ 1/2 + u\ 1/2 + u,\ 1/2 + u\ 1/2 - u\ 1/2 - u \\ 1/2 - u\ 1/2 + u\ 1/2 - u,\ 1/2 - u\ 1/2 - u\ 1/2 + u \end{array}$$

The closest agreement between the calcd. and exptl. intensity was found for values of u around 0.17. The radius of the neutral F atom is approx. 0.50 A. U. C. C. DAVIS

An x-ray study of mannitol, dulcitol and mannose. THORA C. MARWICK. *Nature* **127**, 11–2(1931).—Results:

	Space group	a A.	b A.	c A.	Density g./cc.	Molecules per cell
Mannitol	O_4	8 65	16.90	5.56	1.497	4
Dulcitol	C_{2h}^5	8.61	11.60	9.05	1.466	4
Mannose	O_4	7.62	18.18	5.67	1.501	4

In all three compds. the long dimension of the mol. probably corresponds to the a-axis. C. J. HUMPHREYS

The crystallographic character of the amides of methylbutenoic acids. J. THOREAU *Bull. sci. acad. roy. Belg.* [5], **16**, 823–8(1930); *Bull. soc. chim. Belg.* **39**, 412–6.—The amide of tiglic acid gave orthorhombic crystals with 8 faces. The amide of angelic acid gave long crystals but could not be measured by the goniometer. The amide of α-ethylacrylic acid gave long monoclinic crystals, and that of methylethylglycolic acid gave monoclinic crystals. WALLACE R. BRODE

Conductivity of the crystals of sodium chloride. A. K. WALTHER AND B. M. HOCHBERG. *J. Russ. Phys.-Chem. Soc.*, Phys. Pt. 62, 399–408(1930).—The cond. of NaCl crystals was investigated for the temp. range 25–800°. Polarization and its influence on the cond. were studied. The change in the cond. with temp. above 550° is attributed to the transport of electricity by Cl ions. The cond. between 25° and 550° was expressed by the equation $\delta = Ae^{-B/T}$, where δ is the sp. conductance, T the abs. temp. and A and B are consts. for a given substance and are connected with the work done in the sepn. of ions from the crystal lattice. The deviation from the above equation at temps. higher than 550° is attributed to migration of Cl ions. V. V

Zero volumes of crystalline organic substances. W. BILTZ. *Z. Elektrochem.* 36, 815–8(1930).—A discussion of the mol. vol. and its relationship to the additivity and constitutional properties of the at. vol. Plotting the mol. vol. of homologous series against the no. of C atoms gives a value of 13.7 cc. for the $-CH_2$ group, and 33 cc. for the aromatic $-C_4H_2$ group. The empirical increment for the individual groups thus the zero vols. of the elements to be calcd. $C_{(aromatic)} = 5.4$ = graphite; $_{\text{hatic)}} = 3.4$ = diamond; H = 5.8 = 1/2 H atom; O″ = 10.9 = 1/2 O atom; = 3.6 = 1/2 O atom. The zero vols. of the oxides of N are discussed. The calcd. zero vol. for the $-CH_2$ group is 15.0, whereas the av. observed value is 13.7. The energies

of decompn. and the spatial requirements are roughly proportional. The exceptionally large zero vol. of CH_4, calcd. 26.6, observed 30.65, needs to be clarified. Staudinger's study of polyoxymethylene diacetates is considered. L. L. QUILL

Relations between thermal force, thermolysis and ionic mobility in solid salts and mixed crystals. H. REINHOLD. *Z. physik. Chem.* Abt. B 11, 321–41(1930); cf. *C. A.* 22, 3358.—Chiefly math. L. P. HALL

Some reactions that take place in the solid state. MME. MATHIEU, MATHIEU AND PAIĆ. *Compt. rend.* 192, 416–8(1931).—Reactions take place readily in the solid state but they are difficult to follow unless there is a change in color or evolution of gas. The changes in x-ray spectra before and after reaction prove that the following reactions take place when the mixts. of solid powders are heated: (*1*) $Hg + I_2 \longrightarrow HgI_2$, (*2*) ZnS (wurtzite) $\longrightarrow$ ZnS(blende), (*3*) $3K_2SO_4 + Na_2SO_4 \longrightarrow Na_2SO_4.3K_2SO_4$, (*4*) $HgSO_4 + 2HgO \longrightarrow 3HgO.SO_3$, (*5*) $HgSO_4 + HgI_2 \longrightarrow HgSO_4.HgI_2$, (*6*) $(PbI)_2CO_3 \longrightarrow PbI_2 + PbCO_3$, (*7*) $[3HgO.2SO_3.2H_2O] + 3HgO \longrightarrow 2[3HgO.SO_3] + 2H_2O$. Reactions *1*, *4* and *6* take place with increase in mol. vol., reactions *2* and *3* with decrease, and reaction *5* with no change in mol. vol. Application of thermodynamics to reactions in the solid state is not yet practicable. F. L. BROWNE

Spiral-shaped cracks in the drying of precipitates. G. SCHIKORR. *Naturwissenschaften* 18, 376(1930).—$Fe(OH)_3$ was pptd. from $FeCl_3$ soln. with NH_3, filtered and washed and about 50 g. of the moist ppt. was placed on a glass plate and allowed to dry in the air. After 8–10 days, there was formed in the course of a few hrs. on the bottom surface a regular spiral-shaped crack. This spiral formation takes place also with $Al(OH)_3$. No explanation of the observed phenomenon is given. L. T. C.

Spiral formation in chemical precipitation. R. ED. LIESEGANG. *Naturwissenschaften* 18, 645–6(1930).—Spiral cracks during the drying out of gels recently described by Schikorr (preceding abstr.) are a modification of ordinary rhythmic ring formation in ppts., etc. Its exact cause has so far not been explained. B. J. C. VAN DER HOEVEN

The density of atmospheric air and its variations. E. MOLES, M. PAYA AND T. BATUECAS. *Rev. acad. cienc. Madrid* [2], 25, No. 10, 95 170(1930).—An historic review of the studies of the d. and chem constituents of air followed by extensive original investigations. Methods used to det. the individual factors are described in detail, and drawings are presented of the app. used. Air samples were taken from various localities. B. S. LEVINE

Change of density of ethyl ether with temperature. J. MAZUR. *Nature* 127, 270 (1931); cf. *C. A.* 25, 627.—The d. of very pure Et_2O increases from 0.6964 at 35° to 0.8595 at —105.4°, below which the rate of increase of d. is much slower. This checks the transition temp. found in the detn. of sp. heat and dielec. const. At the m. p. —117.2° d. is 0.8654. ARTHUR FLEISCHER

The nature of specific properties of molecular surface fields. The structure of active carbons and the inversion of the effects of adsorption and wetting heats. B. IL'IN AND I. SIMANOV. *Z. Physik* 66, 613–8(1930).—Exptl. data are given on an inversion of the adsorption from aq. fatty acid solns. and also an inversion of the wetting heat in the homologous alc. series by two modifications of active carbon prepd. from sugars. The Debye figures of these carbons are considered. M. MCMAHON

Interface potential and reactions at surfaces. I. Reduction of permanganate by charcoal. A. WASSERMANN. *Z. physik. Chem.*, Abt. A, 149, 223–39(1930).—The actions of different charcoal prepns. on $KMnO_4$ soln. were comparatively investigated. If the velocity of reduction of the $KMnO_4$ is a measure of the diffusion of the MnO_4 ion to the interface, the surface charge on the charcoal should influence the velocity of decompn. The effect of p_H on the reaction velocity in the acid region confirms this assumption. Also $KMnO_4$ is reduced about equally readily by normal and by activated sugar charcoal in alk. soln. where both charcoal surfaces are negatively charged, whereas in acid soln. the positively charged active charcoal is the more active. The fact that the velocity of reaction in alk. soln. is independent of the concn. of the alkali is explained by supposing that the C adsorbs OH ions only in small amts. B. C. A.

Note on the adsorption theories of Frenkel and Hückel. A. GANGULI. *Z. Physik* 66, 704–7(1930); cf. *C. A.* 24, 2656.—The adsorption equations of F. (*C. A.* 18, 3302) and H. (*Adsorption und Kapillarkondensation*, p. 172) are identified with G.'s statistical derivation of the Langmuir adsorption isotherm. CHANNING WILSON

A study of adsorption processes. II. V. N. KRESTINSKAYA. *J. Russ. Phys.-Chem. Soc.* 61, 2111–32(1929); cf. *C. A.* 22, 9.—Prolonged sorption by C of acetic and benzoic acids is not due to the formation of solid solns. or to chem. reactions. It is merely an adsorption, which is conditioned by a slow diffusion of dissolved substances. Benzoic and acetic acids are adsorbed by charcoal in equiv. quantities. V. V.

The adsorptive bond. H. CASSEL AND F. SALDITT. *Naturwissenschaften* **19**, 110–1 (1931).—The surface tension, σ, of pure Hg was measured by the method of maximal drop-pressure in the absence of air and impurities and in the presence of its own vapor and several other vapors at different p and T. The σ-p isotherms allow calcn. of the adsorbed amts. by the Gibbs method. This procedure is an ideal one for testing the dipole theory of adsorption (Debye, *Physica* **1**, 362(1921); Lorenz and Lande, *C. A.* **17**, 3818; Magnus, *C. A.* **21**, 844). In accordance with London and Polanyi (*C. A.* **25**, 1715; and London, *C. A.* **25**, 1715) the dipole moment plays only a secondary role in adsorption. H_2O vapor, between 0° and 50° and at pressures up to 62 mm. Hg, had no effect at all on the surface tension of 0.1% accuracy; this means that it is not adsorbed below satn. pressure. Considerable adsorption was found for Et_2O with a much smaller dipole moment, more still for hexane, cyclohexane and benzene in the order mentioned (different from the order for mol. refraction) which are without dipole moment. MeOH, EtOH, and PrOH are adsorbed more strongly with increasing chain length. The S-shape of the σ-p curves proves that the adsorbed state is an assocd. one. Nitromethane shows the same behavior. It would seem that dipole qualities by themselves even act as a deterrent to adsorption. B. J. C VAN DER HOEVEN

Occlusion of hydrogen by platinum black. A. SIEVERTS AND H. BRÜNING. *Festschr. Heraeus* **1930**, 97–114.—For a particular temp. and pressure the sorption of H by Pt black depends on the previous treatment of the latter. The isobars exhibit a change of direction between 0° and —20°, becoming again rectilinear between —20° and —120°. B. C. A.

Desorption of gases from molecularly plane glass surfaces. JAMES R. CURRY. *J. Phys. Chem.* **35**, 859–73(1931).—The desorption of air, CO_2, $C_6H_5CH_3$, NH_3, H_2, CO, and C_2H_4 from glass surfaces was studied, in an app. with a large ratio of surface : vol and a plane surface. The adsorbed gas covered only a fraction of the surface Desorption was complete at temps. below 220°. S. LENHER

The heat of adsorption of certain organic vapors by charcoal at 25° and 50°. J. N. PEARCE AND G. H. REED. *J. Phys. Chem.* **35**, 905–14(1931); cf. *C. A.* **24**, 3690.—The heats of adsorption of CH_3Cl, CH_2Cl_2, $CHCl_3$ and CCl_4 on charcoal were detd. at 25° and 50°. There does not appear to be a temp. coeff. of the heats of adsorption. The mol. heats of adsorption increase with the no. of Cl atoms in the mol. S. L.

Chemical sorption. IV. Complex sorption processes and hydrolysis. S. LIPATOV AND N. SOKOLOVA. *Z. anorg. allgem. Chem.* **192**, 383–90(1930); cf. *C. A.* **24**, 766, 2355.—The adsorption of NaOH by salt-free cellulose films was detd Corrections were made for swelling. Na ions are adsorbed at the positions of the OH groups of the cellulose Max. adsorption shows 3 NaOH combined with each $C_6H_{10}O_5$. The swelling of cellulose reaches a max. at 10% of NaOH. H_2O covers the cellulose in NaOH solns. with a monomol. film. ARTHUR FLEISCHER

Adsorption in solutions in relation to the dielectric properties of the solvent. I. E. HEYMANN AND E. BOYE. *Z. physik. Chem.*, Abt. A, **150**, 219–56(1930); cf *C. A.* **25**, 13.—The relation between dielec. properties of solvents and adsorption of solutes is discussed theoretically and investigated exptly. Purified, almost ash free wood char coal was the adsorbent. Adsorption of BzOH, AcOH, CH_2O_2, butyric acid and I (violet solns. only) is weak from strongly polar solvents and strong from weakly polar solvents. This antibatic relation between dipole moment and adsorption is not universal, however, and is probably influenced by the mutual affinities of solute and solvent This suggestion is supported by the observation that I is much more weakly adsorbed from brown solns. in alc., Et_2O and C_6H_6, where it is solvated, than from violet solns., where there is practically no solvation. A definite and const. relation between dielec properties and adsorption occurs only in solvents that are closely related chemically, such as a homologous series of alcs. The adsorption of BzOH or picric acid in alc. soln. by charcoal decreases with increasing mol. polarization of the alc., *i. e.*, with increasing deformability of the mol. A similar relation is found between adsorption and dipole moment in the adsorption of I from the series of chloromethanes. An investigation of adsorption in solvent mixts. was also made, and a connection established between the adsorption curve (relating percentage adsorption to the compn. of the mixt.) and the mol. polarization curve. In general, there are two types of behavior. Adsorption curves are linear when both components of the solvent mixt. are non-polar (C_6H_6—CCl_4) or when one component is polar but when its sp. polarization is not altered appreciably by the presence of the non-polar solvent (mixts. of C_6H_6 with PhMe, $CHCl_3$ or PhCl). Complicated curves showing one or more minima are obtained when the sp. polarization of the polar component is altered by admixt. with the non-polar component (C_6H_6 with $PhNO_2$ or alc., CCl_4 with alc. or Me_2CO), or when both components are polar. In such

cases the max. polarization corresponds with the min. of adsorption. Adsorption in solvent mixts. is further discussed in relation to vapor pressure and soly. B. C. A.

Oxide hydrates. XXXV. The crystallized oxides and oxide hydrates of aluminum as adsorbents for organic dyestuffs. GUSTAV F. HÜTTIG AND ALFRED PETER. *Kolloid-Z.* **54**, 140–7(1931); cf. *C. A.* **24**, 2075, 5654.—The adsorption of methyl violet, methyl blue, Congo red, eosin and Bordeaux red *R* by artificial hydrargillite, boehmite, γ-Al_2O_3 (Willstätter), corundum and natural hydrargillite, bauxite and diaspore was detd. In neutral solns. the adsorption follows Freundlich's isotherm. With the natural ores the accessory minerals play an important part in the adsorption. The oxides in order of decreasing adsorption are: boehmite, γ-Al_2O_3, diaspore, artificial hydrargillite, corundum. Selective adsorption is greatest for corundum, while boehmite shows hardly any selective effect. ARTHUR FLEISCHER

Direct measurement of the adsorption of soluble substances by the bubble method. DAVID M. GANS AND WM. D. HARKINS. *J. Phys. Chem.* **35**, 722–39(1931).—The adsorption of *p*-toluidine and isoamyl alc. in the air-soln. interface was measured by the bubble method. The adsorption exceeds that deduced from the equation, $u = (1/RT)(\delta\gamma/\delta \ln a)$, in agreement with measurements of McBain and Davies (cf. *C. A.* **21**, 3510) although the adsorption is, in general, smaller. As the adsorbing bubbles grow smaller adsorption appears to decrease, approaching the value for the solute obtained from the adsorption equation. S. LENHER

Separation and size distribution of microscopic particles. An air analysis for fine powders. PAUL S. ROLLER. Bur. Mines, *Tech. Paper* **490**, 46 pp.(1931); cf. *C. A.* **25**, 364.—The various methods for the particle-size analysis of a microscopic powder are described. The principle, construction and operation of an improved air separator are described. Results for the sepn. of portland cement and chrome-yellow pigment in steps of 0–5, 5–10, 10–20, 20–40, 40–60 and 60–100μ are given in detail. A closer sepn. beginning with 0–3μ was made for gypsum and anhydrite. For soft powders only, in the 0–5μ range, there is an attrition of the grains. Quant. methods for correction are described. A size-distribution analysis of the particles of each of the fractions made under the microscope showed that Stokes' law is closely obeyed. In each fraction there is a small overlap of a few μ due to irregularities in the shape and surface of the grains, inhomogeneity of the density of the grains, and incompleteness of fractionation. The most important particle-size properties of a powder are those that relate to the surface per unit wt. The mean diam. is defined therefore in relation to the sp surface. The surface mean diams. for the cement powder and chrome-yellow pigment are 9.6 and 6.1μ, resp. The dispersion is a measure of the extent of the distribution of the particle diams. about the mean diam. of the microscopic powder. The surface dispersion, related to the surface diam., is calcd. as 13.3 and 6.1 for the cement and pigment, resp. The latter is therefore twice as homogeneous as the cement. General graphic methods are described with reference to a frequency distribution of the particle diams. The method in which the area under the curve between 2 diams. gives the surface area of the particles per g. of powder between these diams. is described in detail. ALDEN H. EMERY

Triangular diagrams for the graphic representation of colloidal systems. A. DUMANSKII. *Kolloidchem. Beihefte* **31**, 418–33(1930).—By the use of triangular diagrams the effect of such peptizing agents as polyhydroxy alcs., sugars and hydroxy acids upon the reaction between $FeCl_3$ and NaOH or NH_4OH is shown clearly. By this means it is possible to show the range of stability of the pos. sol, the stability of the neg. sol and the concns. at which pptn. takes place. Peptization conditions for the pptd. $Fe(OH)_3$ by peptizing agents are shown well by this means. Sensitized and stabilized regions of such hydrated sols as gelatin due to the addn. of org. substances like EtOH are also represented by these diagrams. The coagulation of hydrophilic and hydrophobic colloids under changing concns. of solvents having 3 components, *i. e.*, water, alc. and ether are shown by the same method. The diagrams also find useful application in representing emulsification and foam formation in the realm of colloids. L. H. R.

A note on the complexity of the magnetic properties of elements in the colloidal state. S. S. BHATNAGAR. *J. Indian Chem. Soc.* **7**, 957–8(1930).—Both powd. and colloidal Bi contain oxide. BiO is weakly diamagnetic or even paramagnetic. A strip of Bi tarnished by dipping in HNO_3 is less diamagnetic than the original. That colloidal metals such as Bi are less diamagnetic than crystals of the metal (see Vaidyanathan, *C. A.* **24**, 3149) is at least partly due to the presence of oxides. O. T. Q.

Observations on the dielectric behavior of dispersed systems. R. FRICKE AND L. HAVESTADT. *Z. anorg. allgem. Chem.* **196**, 120–8(1931); cf. *C. A.* **24**, 3183.—Changes of dielec. const. were measured for suspensions of ThO_2 hydrate, $Al(OH)_3$ hydrate and

stannic acid, on adding small quantities of NaOH and HCl. The dielec. const. was decreased in each case. This decrease can be correlated with changes in the characteristics of the suspensions. The relationship is not as clear as F. and H. previously thought. The time change of the dielec. const. was measured for a gelatin soln.; the results apparently disagree with the data for stannic acid. Colloidal Au suspensions show practically the same dielec. const. as pure water. The theory of Szegvari and Wigner (*C. A.* 18, 492) is criticized. E. J. ROSENBAUM

Preparation of an electrolyte-free sol of manganese dioxide. SHRIDHAR S. JOSHI AND T. SURYA NARAYAN. *J. Indian Chem. Soc.* 7, 883–5(1930).—MnO_2 sol was prepd. by adding concd. NH_4OH drop by drop to boiling $KMnO_4$ soln. Although the sol coagulated slowly when in contact with unglazed porcelain, animal charcoal, celluloid, glass-wool, filter and parchment papers, it could be successfully purified by dialysis with a parchment membrane by either of two methods. Application of a sufficiently high neg. potential to the membrane prevented coagulation until the sol became practically electrolyte-free. In one expt. a pos. potential of 200 volts caused coagulation in 10 min.; zero potential allowed coagulation in 30 min.; a neg. potential of 200 v. prevented coagulation for over 13 hrs. Sols purified by dialysis at high neg. potentials were very sensitive to added electrolytes. The impure sol could also be purified by hot dialysis. If coagulation were caused by chem. reaction with the membrane substance, hot dialysis would have been impossible because of the temp. coeff. of reaction rate. The increased stability in hot dialysis is ascribed to diminution of the adsorption of colloid by the parchment. OSCAR T. QUIMBY

Colloidchemical studies of dye sols. II. The solution of Congo acid sols by neutral salts. R. TANAKA. *Kolloid-Z.* 54, 156–64(1931); cf. *C. A.* 25, 631.—The color of the soln. and the ppt. was noted on adding varying amts. of KI, KCl, $Ca(NO_3)_2$ and $CaCl_2$ soln. to Congo red sol. A change of color to red appears at the soln. max., a point independent of the p_H of the soln. $CaCl_2$ showed the greatest effect. A. F.

Dispersoidal investigations on selenium. I. KIYOSHI JUNA. *Bull. Chem. Soc Japan* 6, 23–4(1931).—Se sols are formed when Se solns. in hydrazine hydrate are poured into H_2O, C_2H_5OH, or glycerol in the presence of air, O_2, or CO_2 but not in a N atm. ARTHUR FLEISCHER

The effect of stirring on the rate of coagulation of gold sol. EMLYN JONES. *Trans Faraday Soc.* 27, 51–8(1931).—The effect of stirring was detd. by calcg. β in the von Smoluchowski formula from coagulation expts. with $BaCl_2$ on a Au sol made by acetone reduction. For fast coagulation, β increases with increasing rate of stirring; for slow coagulation, β decreases with increasing rate of stirring. ARTHUR FLEISCHER

Coagulation. G. WIEGNER. *J. Soc. Chem. Ind.* 50, 55–62T(1931); cf. *C. A.* 22, 4311, 4312; 23, 750, 1552.—The work at Zurich on rapid and slow perikinetic coagulation of monodisperse systems, rapid perikinetic coagulation of polydisperse systems, rapid and slow orthokinetic coagulation, rapid and slow perikinetic coagulation of needle-shaped particles and the coagulation of oppositely charged colloids is reviewed ARTHUR FLEISCHER

The measurement of permeability of porous alundum disks for water and oils. HOLBROOK G. BOTSET. *Rev. Sci. Instruments* 2, 84–95(1931).—Lab. expts. were conducted to gain a more accurate knowledge of the flow of liquids in underground reservoirs. The app. consisted of a vertical brass tube in which a porous disk was placed The flow through the disk was collected and measured in a graduate. The first expts with water indicated that the decrease of the rate of flow with time was due to hydrolysis of the glass reservoir by the water in which H_2SiO_3 was formed. With kerosene, the decrease in the rate depends on the presence of unsatd. hydrocarbons. This is also true for a light lubricating oil. Expts. with a crude oil showed that dissolved O_2 decreases the rate of flow. It is concluded that when both O_2 and unsatd. hydrocarbons are present the rate of flow of an oil through a porous disk decreases, but the removal of either one permits a const. rate, because clogging of the disk is caused by the oxidation products of the unsatd. hydrocarbons. Permeability measurements applied to field conditions are questionable unless it is known that the oils tested contain no unsatd. hydrocarbons or are tested in the absence of air. ALLEN S. SMITH

Membrane and osmosis. I. F. A. H. SCHREINEMAKERS. *Rec. trav. chim.* 50, 221–9(1931); cf. *C. A.* 24, 4686.—Theoretical. When a membrane, permeable only to H_2O, separates two liquids that differ in *O. W. A.* (osmotic water action), the direction of osmosis depends upon the *W*-amt. given to the membrane by the liquid. If the pressure is the same on both sides of the membrane, H_2O diffuses toward the liquid giving the membrane, the smaller *W*-amt. If the membrane is homogeneous, water diffuses

toward the boundary plane with the smaller W-amt. Through a heterogeneous membrane, however, diffusion in the opposite direction is possible. F. L. BROWNE

Disturbance of neutrality of solution in electrodialysis, the facts and the explanation. SHUMPEI OKA. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding 4–9(1931).—A soln. tends to lose neutrality during electrodialysis unless special precautions are taken. The prevailing theory is that the electrokinetic potential of the diaphragm membrane, the ζ potential, alters the mobility of the ions while passing through the capillary pores of the membrane. Parchment paper and collodion membranes decrease the transport no. of anions and increase that of cations. With a pair of such neg. diaphragms in a 3-compartment cell, cations are removed more rapidly than anions, and the soln. becomes acid. Solns. of 0.005 N KCl were electrodialyzed in a glass container having 3 chambers sepd. by 2 similar diaphragms. The H_2O in the electrode chambers was not renewed during an expt. The diaphragms were parchment, or filter paper impregnated with collodion or with chromated gelatin. The ζ potential of the diaphragms against 0.005 N KOH, KCl and HCl were detd. With a const. applied voltage the current at first increased, reached a max., then decreased. The p_H of the soln. decreased promptly, reached a low and nearly const value, then increased gradually. The current-time and current-p_H curves for parchment and for collodion, with 50 v., nearly coincide, although the ζ potential of collodion was 10 times that of parchment. When the p_H of the soln. is plotted against total watts consumed for expts. at different const. voltages with a given membrane the curves coincide, showing that change in p_H with a given membrane depends solely upon the amt. of current passed. Current is carried by K^+ ions from the central to the anode chamber, by H^+ ions from the central to the anode chamber, and by OH^- ions from the cathode to the central chamber. The acidity or basicity of the soln. is detd. by the relative amt. of H^+ ions coming from the anolyte, and of OH^- from the catholyte. The prevailing theory is modified by attributing the change in p_H to two variables instead of to one only, (*1*) the ζ potential of the diaphragm, and (*2*) the concns. of ions in the diaphragm. E. M. SYMMES

Physicochemical properties of clays. I. Base exchange or ionic exchange. G. WIEGNER. *J. Soc. Chem. Ind.* **50**, 65–71T(1931).—Permutites and clays with exchange properties are micelles consisting of an ultramicron, an inner layer of anions, and an outer swarm of cations. The displacement of ions by exchange depends on the attractive forces between the inner and outer layer as well as upon the hydration of the ions. The ionic exchange determines the elec. potential of the micelles and also their behavior on coagulation. The water content and viscosity as well as the plasticity and cohesion of clay are in accord with the hydrations of the ions in the outer swarm. F. L. BROWNE

The optimum conditions for the formation of silica gel from alkali silicate solutions. II. R. C. RAY AND P. B. GANGULY. *J. Phys. Chem.* **35**, 596–601(1931); cf. *C. A.* **24**, 2358.—The optimum conditions for formation of SiO_2 gel by the action of HCl on Na_2SiO_3 of 1:3.3 and 1:4 ratios were studied. The limiting p_H ranges in which gel formation takes place were detd. The large amt. of SiO_2 in the higher ratio does not affect the conditions of gel formation. The amts. of heat evolved when 1 mol. of $FeCl_3$ reacts with Na_2SiO_3 solns. of different ratios were also detd.; the heat of reaction decreases with increase in the ratio of SiO_2/Na_2O from 1:2 to 3:4. The reaction between $FeCl_3$ and Na_2SiO_3 solns. results mainly in the formation of ferric silicates. H. W. LEAHY

Molecularly dispersed, dissolved silicic acid and titanic acid. H. BRINTZINGER AND W. BRINTZINGER. *Z. anorg. allgem. Chem.* **196**, 44–9(1931); cf. *C. A.* **24**, 11.—Tetraethyl orthosilicate was sapond. by 0.002 N HCl. Detn. of the dialysis coeff. of portions of the resulting soln. that had stood for different lengths of time made it possible (*1*) to det. whether one or several species of mol. of silicic acid were present after a given time, (*2*) to det. the mol. wt. when a single species was present and (*3*) to follow the condensation of the silicic acid from the rapidly diffusing, disilicic acid, through the more slowly diffusion molecularly dispersed forms, to the colloidal ones, which no longer pass through cellophane membrane. The soln. of the freshly sapond. ester contained disilicic acid, $2SiO_2.2H_2O$, mol. wt. 153. After standing 1 day this had condensed to $4SiO_2.3H_2O$, mol. wt. 290. After 1 more day the silicic acid was present as $8SiO_2.4H_2O$, mol. wt. 549. After 4 days the mol. wt. was 862. For many subsequent days the soln. seemed to contain a mixt. of differently aggregated acids. In the 45-day old soln. a silicic acid of mol. wt. 8260 seemed to be stable, but interpretation of the results for solns. of such high mol. wt. is uncertain. 0.001 N HCl sapond. the ester more slowly than did 0.002 N HCl, so that drops of unsapond. ester persisted for a considerable time. Local action at the surfaces of the drops tended to produce nonuniformity of the species of silicic acid mol. present in the soln. However, the 0.001 N HCl seemed to stabilize

the molecularly dispersed silicic acid less readily than did the 0.002 *N*, because the change in state of mol. aggregation was more rapid. Even so, the presence of silicic acids of mol. wt. 8260 and 32,870 were noted. Orthotitanic acid tetraethyl ester, dissolved in MeOH, was saponified in H_2O and in 0.001 *N*, 0.01 *N* and 0.1 *N* HCl. The dialysis coeff. indicated that titanic acid is capable of forming molecularly dispersed acids, but that they are only slightly stable and alter rapidly to colloidally dispersed TiO_2 hydrate. The soln. of sapond. titanic acid ester stiffens to a jelly after 6 to 22 hrs. Gelatinous silicic acid is formed as the result of the sapon. of Et orthosilicate in a mixt. of H_2O + EtOH (100:1), after several weeks, providing opportunity is afforded for the alc. to evap. Cf. *C. A.* **24**, 1812, 3191. R. H. LOMBARD

Changes in the viscosity of gelatin sols in the process of gelation. S. N. BANERJI AND S. GHOSH. *J. Indian Chem. Soc.* **7**, 923-31(1930).—Gelatin sols of various concns. (2–10%) were prepd. and divided into 2 parts. Part I was kept at 50° and part II was allowed to gel and then kept at 25°. Parts I and II were then brought to an intermediate temp. at which viscosity measurements were made with an Ostwald viscometer The viscosity of I increased and that of II decreased with time. Such effects are greatest near the gelation temp. Inoculation of gelatin sols near the gelation point with gel of the same concn. causes an abrupt increase in viscosity which is greater the nearer the temp. is to the gelation point. OSCAR T. QUIMBY

Simultaneous action of electrolytes and alcohol on gelatin below the isoelectric point of Michaelis. ST. PRZYLECKI. *Compt. rend. soc. biol.* **106**, 134–6(1931); of *Compt. rend. soc. biol.* **104**, 1079(1930).—In a study of the action of salts and acids on gelatin solns. to which alc. had been added the following results were obtained. (*1*) Action of acids: HCl impedes the coagulation up to a certain limit. The action of H_2SO_4 is much less marked. HCl added to the sulfate of the gelatin diminishes the H_2SO_4 coagulation. (*2*) (*a*) Action of salts on the chloride of gelatin: NaCl, $MgCl_2$, $CaCl_2$, $AlCl_3$ or $FeCl_3$ added in varying amt. to a soln. of 10 cc. of gelatin contg. 5 millimol. of HCl (p_H 1.8) causes no opalescence. $MgSO_4$, Na_2SO_4 or $Fe_2(SO_4)_3$ causes a strong coagulation in solns. varying from 0.5 to 6 millimol. The addn. of HCl to this gelatin does not affect the coagulation phenomena. If Na_2SO_4 is replaced by H_2SO_4 merely a simple opalescence is observed. The differences between the action of Na_2SO_4 and H_2SO_4 do not depend on the differences of p_H but on the differences of the influence of the particles of gelatin on the potential. The SO_4 ion perhaps causes this potential to fall below the minimum necessary to stabilizing the sol so that salts with multivalent cations protect the sol against the coagulation provoked by Na_2SO_4. (*2*) (*b*) Action of salts on the sulfate of gelatin: The coagulating action produced by large doses of H_2SO_4 is diminished by HCl, $MgCl_2$ or $AlCl_3$ (a peptizing action depending on the valence of the cation). ALBERT L. RAWLINS

Thermal disaggregation of gelatin. (Röntgenographic study of its degradation.) O. GERNGROSS, O. TRIANGI AND P. KOEPPE. *Ber.* **63B**, 1603-14(1930).—Electro-osmotically purified gelatin contg. 0.13% of ash is heated in Jena glass vessels in 25% soln. of exactly isoelec. reaction for 24, 72, 75 and 336 hrs. at 100° and 48 hrs. at 121°. Possible peptide degradation is examd. by measurement of increase of the free amino groups according to Van Slyke (*C. A.* **23**, 5207), by alkalimetric detn. of free carboxyl groups according to Willstätter and Waldschmidt-Leitz (*C. A.* **16**, 944), and by the CH_2O no. Phys. changes are followed by measurements of the viscosity of the solns. and observations on mutarotation and the gelatinizing power of the heated sols. Even after 75 hrs. at 100° there is no sign of a chem. valency degradation by rupture of peptide linkings, whereas the gelatinizing power is completely destroyed, the viscosity reduced to 18.8%, and the mutarotation to 28.4% of the initial value of the intact gelatin. Protracted heating at 121° or exposure for 336 hrs. at 100° causes distinct, true hydrolysis. In slightly acid soln. (p_H 1.8) much more pronounced peptide degradation is observed after 8 hrs. at 100°. On the basis of detns. of mol. wt. and x-ray diagrams, the following picture of the structure and thermolysis of gelatin is drawn. Intact gelatin gels consist of extended structures that arise from extra-mol. union of the gelatin particles. In aq. soln. of concn. lower than 0.5% at 20° these individual particles, according to the previous history of the prepns., have a mean mol. wt. of 50,000–90,000 if the reaction is isoelec. The particles undergo an almost completely reversible distribution into mols. of mean mol. wt. of a few thousands when the solns. are heated for a short period at 100°, but, even under these conditions, an irreversible change that reduces the mol. wt. of the intact material is also obvious. Protracted ebullition causes the formation of individual mols. (mean wt. 4500), which do not recombine to aggregates when cooled; the power of forming gels or viscous, adhesive solns. is lost. It is assumed that the mols. of the intact gelatin are not united to the structures of mol. wt. 90,000 by main

valency forces, but this is not established with certainty. Reaggregation of the thermolyzed particles is observed to a certain degree if the solns. are evapd. to dryness and the residue is dissolved in water. B. C. A.

Swelling of cellulose in perchloric acid. K. ANDRESS AND L. REINHARDT. *Z. physik. Chem.*, Abt. A, **151**, 425–32(1930); cf. *C. A.* **22**, 4795.—Adsorption of $HClO_4$ by cellulose from aq. soln. at 0° indicates that above the limiting concn., 9.3 *M*, an addn. product is formed, $2C_6H_{10}O_5.HClO_4$, which shows a characteristic Röntgen diagram, the elementary unit having the dimensions: $a = 16.5$, $b = 10.3$, $c = 10.7$ A. U., $\beta = 93°$. Below this concn. the product after being washed with water gave diagrams characteristic of the native fiber. At higher concns. esterification begins, and above 10.6 *M* the fiber is destroyed. W. L. HILL

Structure of the crystal lattice of cellulose. W. T. ASTBURY AND THORA C. MARWICK. *Nature* **127**, 12 3(1931).—It is reasoned from crystallographic data for native and hydrated cellulose and sugars, that the six-atom sugar ring in the cryst. state possesses certain approx. const. linear dimensions, and that at least one of these dimensions usually corresponds to one of the axial lengths of the unit cell. The structures of native and hydrated or mercerized cellulose may differ in that the plane of the hexagonal glucose residues in native cellulose lies parallel to the *a* axis, while in hydrated cellulose the plane of the rings lies more nearly parallel to the *c* axis C. J. HUMPHREYS

Cellobiosan and cellulose. K. HESS AND E. GARTHE. *Naturwissenschaften* **19**, 180–1(1931).—Freudenberg (*C. A.* **24**, 1213) claimed that the f. p. depressions of AcOH solns. of cryst. biosan acetate (Hess and Friese, *C. A.* **23**, 1118), which is identical with acetylcellulose II (by x-ray), are caused by heat losses due to retarded crystn. of the solns. Recent expts. on the velocities of crystn. indicate that Freudenberg's retardations depend on the choice of exptl. conditions (11° to 15° bath, 0.08° to 0.15° undercooling) which favor heat losses. If sufficiently great undercooling and a bath temp. equal to the "convergence" temp. are used (Raoult, Nernst, Abegg conditions) these abnormal delays do not occur. This reëstablishes the validity of the depressions previously measured. B. J. C. VAN DER HOEVEN

The change in x-ray spectrum of insulin on swelling in water. J. R. KATZ AND J. C. DERKSEN. *Rec. trav. chim.* **50**, 248–51(1931).—Inulin contg. amts. of water varying from the equil. moisture content in satd. air down to equil. over P_2O_5 at 100° was examd. with K_α rays from Cu. A distinct crystal pattern, made up of concentric rings, was obtained. The spectra for inulin satd. with water and air-dry inulin (15% water) are identical. As the moisture content is reduced below about 8%, however, the spectrum changes, both with respect to diam. of rings and their relative intensity. The change in spectrum is therefore connected with the first portions of water taken up by dry inulin, that is, with the first bend in the S-shaped hygroscopicity curve (*C. A.* **11**, 3141). Over much the greater portion of the hygroscopicity curve the spectrum remains unaltered. Conclusion: the swelling of inulin involves not only formation of shells of water around the micelles, but also an absorption of water within the crystal lattice. F. L. BROWNE

Preliminary study of the sol and the coagulum of ichthyocoll. H. G. BUNGENBERG DE JONG AND N. F. DE VRIES. *Rec. trav. chim.* **50**, 238–47(1931).—The ichthyocolla (I) was obtained as a white, amorphous product by extg. the drug ichthyocoll with hot water, centrifuging, filtering, adding enough NaOH to reduce the "alc. no." to a min., pptg., washing with alc. and drying in air. Warm water dissolves I completely. The 0.73% soln. at 37° obeys Poiseuille's law. The curve of p_H *vs.* viscosity is similar to that for gelation within the range p_H 1–4 but differs markedly above p_H 4. Between p_H 5 and 10 the curve for I is very flat, with a min. at p_H 8–9. Sols in the range p_H 6.7–9.3 become turbid on cooling, with a max. turbidity near p_H 9. The isoelec. point also lies between p_H 8 and 9. Above p_H 9 the viscosity increases to a relatively low max. at p_H 12. The viscosity of pos. sols at p_H 4.70, 3.16 and 1.51 is strongly affected by anions of electrolytes according to their valence, but is not affected materially by cations. At p_H 3.16 coagulation is brought about by 10 milli-equivs. of $K_3Fe(CN)_6$. Simple coagula of I can be prepd. with alc., resorcinol, $MgSO_4$, etc. Complex coagula with I as pos. component can be made with gum arabic, yeast nucleate, egg lecithin and soy-bean lecithin. Coagula with I as neg. component can be made with clupein. However, complex coagulation of I with gelatin does not result in aq. medium in the p_H range 5–9, where it was expected. The failure to coagulate is attributed to the flat course of the p_H-viscosity curve. The drawing together of the 2 sorts of particles under the influence of elec. forces is perhaps too weak to overcome their powerful solvation. F. L. B.

Actual prevision of the solubility of substances. FREITAS MACHADO. *Rev. brasil. chim.* **1**, 151–69(1929).—In studying the possibilities of prevision, consideration is

given to the chem. similarity of solvent and solute, the inorg. salts sol. in org. solvents, the soly. of deliquescent salts in alc., the soly. of various solid forms of the same substance, the electro-affinity and soly. of the salts, rule of Bodlaender and the difference in soly. of large and small crystals of the same substance. JOHN M. LADINO

Individuality of the osmotic coefficients for alkali halides. G. KARAGUNIS, A. HAWKINSON AND G. DAMKÖHLER. *Z. physik. Chem.*, Abt. A, **151**, 433–66(1930); cf. *C. A.* **25**, 632.—With the *thermoelec. app.* employed the max. variation in the f. p. detns. of aq. solns. below 0.1 *M* amounted to 0.0002°. The *concn. of* the *solns.* was *detd.* with an *interferometer*, the procedure for its *calibration* being fully described. The calcd. max. error in the mol. lowering of the f. p. is const., 0.2%, for solns. above 0.1 *M*, and is 1–2% for 0.01 *M* solns. Accordingly, the f. p. detns., over the range 0.002–3.0 mol./1000 g. H_2O, were made on KCl, RbCl, CsCl, LiF, NaF, KF, RbF, CsF and NaI, from which the osmotic coeffs. were calcd. and compared. W. L. HILL

The freezing of dilute undisturbed solutions. V. GIAMBALVO. *Z. tech. Physik* **12**, 111–3(1931).—The temp. of max. d. (t_m) decreases faster than the f. p. (t_0) with increasing wt. of solute in water. If t_m and t_0 are plotted against p, parts by wt. of solute per 100 of solvent, the 2 lines meet at a point a. For a soln. freezing in a cylindrical vessel with a nonconducting bottom, 2 typical cases are possible depending on whether $p > a$ and $t_m > t_0$ or $p < a$ and $t_m < t_0$. The form of the ice on the walls was checked for each case with NaCl solns. ARTHUR FLEISCHER

Vapor pressure and heat of dilution. VII. Vapor pressures of aqueous solutions of sodium hydroxide and of alcoholic solutions of calcium chloride. AILEEN M. HAYWARD AND E. P. PERMAN. *Trans. Faraday Soc.* **27**, 59–69(1931); cf. *C. A.* **21**, 1387.—The vapor pressure of NaOH solns. in Ag tubes was detd. by the dynamic method at 30°, 40°, 60°, 70° and 80°. The same method was used for the $CaCl_2$-EtOH solns. from dil to nearly satd. at 20°, 30°, 40°, 50° and 60°. The heat of diln. and the osmotic pressure were calcd., the former agreeing well with exptl. data. ARTHUR FLEISCHER

The determination of molecular weights from dialytic coefficients. H. BRINZINGER AND W. BRINTZINGER. *Z. anorg. allgem. Chem.* **196**, 33–43(1931); cf. *C. A.* **24**, 3695.—The dialytic coeff. k is defined by the equation $c_t = c_0 e^{-kt}$ in which c_0 is the initial concn. and c_t the concn. t min. later. Certain membranes give characteristic values of k such that $k\sqrt{\text{mol. wt.}} = \text{const.}$ With a cellophane membrane (quality 300, Kalle & Co.), the values of this const. deviated from the mean by less than 5% over the mol. wt. range 46(EtOH) to 504 (raffinose). Relatively large amts. of impurities have little influence upon k. Except when the solute is monodisperse (in which case k is independent of time), k decreases with time. A description of the method and app for detg. k are given. Mol. wts. can be detd. in much less time by dialysis than by diffusion. OSCAR T. QUIMBY

(Molecular weight) measurements by the dialytic method. Enzymic decomposition of starch and thermal decomposition of dextrin in the presence of acids. H. BRINTZINGER AND W. BRINTZINGER. *Z. anorg. allgem. Chem.* **196**, 50–4(1930); cf. preceding abstr.—A clear aq. soln. contg. 0.30% starch was treated with diastase and stored at 30°. Addn. of 0.01 g. diastase to one l. of soln. caused the mol. wt. to decrease from 22,900 (at 20 min.) to 450 in 312 hrs. When 0.1 g. diastase was added to one l. soln. the starch was reduced to the maltose stage (mol. wt. 342) in 38 hrs. Two l. of 0.30% dextrin soln. was acidified with 5 cc. of 0.2 *N* HCl and heated at 100° for 860 hrs. During this time the mol. wt. was reduced to about 180, but the solute was not yet monodisperse, *i. e.*, the dialytic coeff. was still decreasing with time. OSCAR T. QUIMBY

The determination of the degree of association of isopoly-acid ions with the aid of dialytic coefficients. H. BRINTZINGER AND W. BRINTZINGER. *Z. anorg. allgem. Chem.* **196**, 55–60(1931); cf. preceding abstracts.—By applying the rule (dialytic coeff.) $\sqrt{\text{mol. wt.}} = \text{const.}$, the ionic wt. of the tungstate ion in aq. $NaNO_3$ solns. was detd. as a function of p_H. Similar detns. were made with molybdate ion in aq. NH_4NO_3 or $NaNO_3$ solns. The results, tabulated below, are in harmony with those of Jander (*C. A.* **24**, 1810).

Type of salt	p_H range	Complexity of ion
Tungstate	4.5–6.5	Hexa
"	6.5–8–0	Mono
Molybdate	1.0–1.8	Dodeca
"	1.8–4–7	Hexa
"	4.7–6.2	Tri
"	6.2–8.0	Mono

OSCAR T. QUIMBY

Electrolyte–water systems. Distribution of the ions of two salts after diffusion through a membrane. H. BRINTZINGER AND W. BRINTZINGER. *Z. anorg. allgem. Chem.* **196**, 61–4(1931); cf. preceding abstracts.—In a soln. of a binary salt the dialytic coeffs. of the anion and cation are necessarily equal (if the concn. is expressed in mols). However, if the soln. contains 2 salts, the faster anion and faster cation tend to pass through the membrane together and, in general, each ion will have a different dialytic coeff. Thus, with tenth-normal solns. and a cellophane membrane, the following coeffs. were obtained: for LiCl and K_2SO_4 in solns. contg. a single salt, 0.739 and 0.574, resp.; for Li, K, Cl and SO_4 ions in a soln. contg. all 4 ions, 0.409, 0.728, 0.882 and 0.361, resp. With 0.1 *N* solns. and a parchment membrane, the following coeffs. were obtained: for LiCl and KI in solns. contg. a single salt, 0.165 and 0.274, resp.; for Li, K, Cl and I ions in a soln. contg. all four ions, 0.142, 0.301, 0.205 and 0.219, resp. O. T. Q.

Experiment to show the removal of ions in double decomposition. FRANK D. MCCLELLAND. *J. Chem. Education* **7**, 1579(1930).—The reactions are carried out in an ordinary cond. cell in which the decompn. of the electrolyte is indicated by the glowing of an elec. lamp. ANN NICHOLSON HIRD

Conductivity data of aqueous mixtures of hydrogen peroxide and organic acids. W. H. HATCHER AND M. G. STURROCK. *Can. J. Research* **4**, 35–8(1931).—Cond. changes on adding H_2O_2 to aq. solns. of formic, acetic, propionic and glycolic acids were observed. Propionic acid gave a sudden increase in cond. on adding H_2O_2, which became const. within 3 hrs. The other 3 acids gave a sudden sharp decrease followed by a gradual increase to a const. value within 4 or 5 hrs. The const. values attained indicated the presence of peracids whose cond. is of the same order as that of the complexes supposed to be formed during the oxidation. J. W. SHIPLEY

The conductivity of electrolytes in nitromethane. C. P. WRIGHT, D. M. MURRAY-RUST AND HAROLD HARTLEY. *J. Chem. Soc.* 1931, 199–214.—The elec. conductivities of LiCNS, NaCNS, KCNS, NH_4CNS, $LiClO_4$, NH_4ClO_4, $TlClO_4$, $AgClO_4$, $HClO_4$, LiI, KI and Et_4N nitrate, iodide, thiocyanate and picrate were measured at 25° in 0.0001–0.002 *N* nitromethane (I) soln., by Frazer and Hartley's method (*C. A.* **20**, 136). Of these electrolytes, only the Et_4N salts show a linear relation between Λ_0 and $\sqrt{c}$; the other solutes give curves represented by the empirical equation: $\Lambda_c = \Lambda_0 - xc^{2/3}$. Extrapolating these curves, the following Λ_0 values are obtained.

Salt	Λ_0	Salt	Λ_0	Salt	Λ_0
KI	122	$AgClO_4$	116.5	$N(C_2H_5)_4CNS$	119.7
LiI	117.5	$TlClO_4$	124.5	$N(C_2H_5)_4ClO_4$	113.4
KCNS	130	NH_4ClO_4	128.5	$N(C_2H_5)_4NO_3$	114.3
$NaClO_4$	122.5			$N(C_2H_5)_4I$	111.2
		($HClO_4$)	127	$N(C_2H_5)_4Pic$	93.5

The observed and calcd. (from the Debye-Hückel-Onsager equation) results for the Et_4N salts agree closely, showing little tendency to ionic assocn. in soln. Those salts that deviate greatly from the ideal are probably highly assocd. This ionic assocn. is not entirely controlled by the elec. forces between the ions. $HClO_4$ is a strong electrolyte in I, while H_2SO_4, HCl, HNO_3, etc., are very weak electrolytes therein. On the addn. of H_2O to I the elec. cond. of electrolytes that deviate widely from the ideal is increased greatly. At 25°, the soly. of H_2O in I is 2%, while the soly. of I in H_2O is 10%. The d. and viscosity of I at 25° are 1.1312 and 0.00627, resp. J. BALOZIAN

The conductivity of electrolytes in nitrobenzene. D. M. MURRAY-RUST, H. J. HADOW AND HAROLD HARTLEY. *J. Chem. Soc.* 1931, 215–19; cf. preceding abstr.—The elec. conductivities of 0.0001–0.002 *N* nitrobenzene (II) solns. of Et_4N picrate and perchlorate, $AgClO_4$ and $HClO_4$ were measured at 25°. As an ionizing agent II behaves similarly to CH_3NO_2, but very differently from hydroxylic solvents. The deviation of each of the electrolytes from the ideal is somewhat greater in II than in CH_3NO_2, indicating that in the former the tendency for ionic assocn. is greater. Et_4N picrate and perchlorate are strong electrolytes, and give Λ_0 values that closely approx. the ideal. These 2 salts give results that agree with those calcd. from the Debye-Hückel-Onsager equation, while those for $AgClO_4$ do not agree. $HClO_4$ is an electrolyte intermediate in strength between the Et_4N and the Ag salts, being appreciably assocd. in II solns. It is a much stronger electrolyte than any other acid, approx. cond. measurements for HCl, $C_6H_5SO_3H$ and trinitrobenzoic acid showing that these are only very slightly dissocd. Extrapolation to infinite diln. of the graph of Λ_0 against $\sqrt{c}$ give the following values for Λ_0; Et_4N picrate = 32.7; Et_4N perchlorate = 37.6; $AgClO_4$ = 38.4; $HClO_4$ = 43. J. BALOZIAN

Influence of the strength of aromatic amines on their reactions. EDUARD HERTEL AND KURT SCHNEIDER. *Z. physik. Chem.*, Abt. A, **151**, 413–9(1930).—Cond. curves were obtained for aniline-HCl (I), α-(II) and β-naphthylamine (III), 4-bromo(or chloro)-1-naphthylamine (IV) and 1-bromo(or chloro)-2-naphthylamine (V) in acetone-water soln., and for the same compds. with the addn. of free amine until further addns. were without effect. Accordingly, if the capacity of the amine to bind H-ions be taken as a measure of its strength, II and III are strong, IV is medium strong and V is weak. The addn. reaction between amines and phenol derivatives in pure acetone as measured by a similar cond. method in conjunction with mol. wt. detns. indicate the same order of reactivity. In the addn. of phenol derivs to amino groups in the crystal lattice the bond, —O—N—, is favored, while the weak ones favor the bond, —N—C—. Medium strong amines with medium strong phenol derivs. yield *complex isomers* (*C. A.* **21**, 1802). The reactivity of amines with ethers (*C. A.* **25**, 855) is parallel with their capacity to add H-ions. W. L. HILL

The relative strengths of bases in non-aqueous solutions. III. ERIC I. JOHNSON AND JAMES R. PARTINGTON. *J. Chem. Soc.* **1931**, 86–92.—The influence of dimethyl-, diphenyl-, phenylmethyl- and γ-pyrone on the rate of esterification of $PhCH_2CO_2H$ in alc.-HCl soln. is studied by calcg. the ratios of the equil. consts. for the formation of complex ions between the H-ion and by each pyrone and by H_2O, resp., applying Lapworth's theory (*C. A.* **3**, 738). The reaction is retarded in the order given by the following compds., H_2O, γ-pyrone, diphenyl-, phenylmethyl- and dimethyl-pyrone, the last named having the greatest effect. Alc. free from aldehyde, ketone and NH_3 is prepd by refluxing 96% spirit for 6 hrs. with half its vol. of well-burnt lime and 2 sticks of NaOH per l., distg. into a flask contg. a lime and soda mixt., refluxing again, distg. into a dry flask the exit of which is guarded with a $CaCl_2$ tube, dropping clean, fresh Ca turnings into it, letting stand for a day, refluxing for 6 hrs., distg. off through a 12-bulb fractionating column and collecting the middle fraction. The esterification is slightly accelerated by small amts. of benzil and furan, and not affected by small amts. of dipropyl and diisopropyl ethers and glycerol. J. BALOZIAN

The dissociation of strong electrolytes in nonaqueous solution. RUDOLF SCHINGNITZ. *Z. Elektrochem.* **36**, 861–74(1930).—The data on nonaq. solns. are reviewed. The Nernst-Thompson rule is valid for all solvents investigated. A more quant. relation for solvents whose dielec. const. is above 6.7 is given by the equation: $1 - \alpha = 65.7 (D\Lambda_\infty \eta_\infty \sqrt{v})$. The behavior of the cond. found by Martin (cf. *C. A.* **23**, 1802), which leads to the assumption of incomplete dissocn., appears to be generally true for other solvents. This action is shown by the fact that the curves for $\sqrt{c}$ are higher than would be expected from the assumption of complete dissocn. On the other hand, the influence of dielec. const. and of ionic charge follow closely the Debye-Huckel theory. Likewise the values of the coeffs. are proportional to the square root of the concn. JOHN R. HILL

The problem of electrolytic dissociation. KARL FREDENHAGEN. *Z. physik. Chem.*, Abt. A, **152**, 321–79(1931).—The true state of affairs does not agree with the assumptions that (*a*) the dissocg. compds. are composed of charged particles held together by *Coulomb forces;* (*b*) the solvents exert a dielec. action on the solutes, according to their dielec. const.; (*c*) ions in soln. are solvated gaseous ions. Dissocn. and soly. do not run parallel to the dielec. const. of the solvent. The electrostatic theory of *electrolytic dissocn.* is untenable. A new theory is proposed. Electrolytic dissocn. is caused by the selective chem. affinity of the solvent's secondary valence forces for the polar components of the solute. A thermodynamic relation between dissocn. in the gaseous and liquid phases is given, by means of which liquid dissocn. may be calcd. from the dissocn. in the gas phase and the distribution no. The new theory reconciles the contrast between strong and weak electrolytes, explains the *dissocn. of pure solvents and molten salts*, focuses attention on *soly. forces* and the *mechanism of electrolytic conductance.* FRANK URBAN

Simple deposition of reactive metals on noble metals. A. S. RUSSELL. *Nature* **127**, 273–4(1931).—U, Ti, W and Mo are deposited on a Hg surface, as expected according to the Nernst theory of electrode potential, when acidified solns. of their salts are shaken with Hg amalgam. The presence of the very slight concn. of metal is detected by their catalytic effect on the evolution of H_2 from H_2SO_4 solns. by pure Zn. The deposited metals are quite insol. in Hg. ARTHUR FLEISCHER

Contact potentials. I. Measurement of the contact potential between metals and insulators. FREDRICH POLEDNIK. *Z. Physik* **66**, 619–31(1930).—The potentials between certain metals and glass and quartz were detd. by an electrometer method.

A filament of glass or quartz in a clip of the metal being investigated, was held between charged plates and the deflection measured. From standardizations with known charges contact potentials were calcd. for Pt, Fe, Cu, Au, Ag, Al, Mg, Zn, Pb and Sn against quartz as +2.22, 1.99, 1.60, 1.60, 1.42, 0.93, 0.93, 0.45, 0.16 and —0.30; against glass +1.15, 1.15, 0.58, 0.58, 0.58, 0.14, 0.14, —0.29, —0.60 and —1.14 v. These potentials were a function of the m. p. of the metals. **II. The potential difference between salts and their saturated solutions.** MARIANNE LEDERER. *Ibid* 632–45.—An electrometer, in which quadrants cut from salts moved over satd. solns., permitted measurement of the charge of the double layer for pairs of salts. The contact potential for solid salt against satd. soln. was —0.18 ± 0.08 v. for NaCl-KCl, —0.04 ± 0.07 v. for NaCl-$NaNO_3$ and —0.21 ± 0.06 v. for $NaNO_3$-$Ba(NO_3)_2$. L. P. HALL

The theory of Nernst. OSCAR DE SOUZA VIEIRA. *Rev. brasil. chim.* **1**, 193–200 (1929).—Nernst's theory is outlined with particular attention to the difference of potential created between the electrode and the saline soln. In the case of $ZnSO_4$ with a Zn electrode the osmotic tension of the ions emitted by the electrode is added to the tension of the preëxisting ions, in order to equalize the tension of the soln. of the metal. The effect of high concn. and successively decreasing concn. in a series of solns. is also discussed. The results conform to the Nernst formula for calcg. the p. d. J. M. L.

The propagation of flame in electric fields. I. Distortion of the flame surface. ERNEST M. GUÉNAULT AND RICHARD V. WHEELER. *J. Chem. Soc.* **1931**, 195–9.—The effect of an elec. field on the shape and speed of the flame-surface during its propagation is studied. The gaseous mixts. (CO and air or O_2 dried over $CaCl_2$ and H_2SO_4), contained in a spherical explosion-vessel of glass, were ignited electrically, and a photographic study (by the "snapshot" method of Ellis and Robinson, *C. A.* **19**, 2747) made of the flame spread, with and without an elec. field (3000 and 5000 v./cm.). The field was produced between two parallel plates of a condenser, placed at the center of the vessel. Photographs show that the normal symmetry of the flame spread is destroyed by an elec field. As soon as the flame touches the condenser plates the system tends to discharge itself, the elec. field being almost entirely destroyed and consequently the flame-surface suffering distortion. The photographs indicate that the movement of the flame-surface may be due to the movement of the heavy pos. ions dragging the flame-surface with them. Transverse to the field there is no change in the rate of growth of the flame, while longitudinally to it the speed of the flame is apparently increased toward the neg. plate of the condenser by the elec. field. J. BALOZIAN

Periodic process in a chemical reaction. W. T. GIBSON. *Nature* **127**, 13(1931).—The peculiar manner of slow oxidation of the K layer in a photoelec. cell that had developed a leak in the glass bulb contg. the material is described. Instead of oxidizing uniformly, sharply marked rings were attacked first. The rings were roughly circular with centers at the crack. These rings remained visible throughout the entire oxidation process. C. J. HUMPHREYS

Chemical reaction between metallic magnesium and salt solutions. (Quantitative Part, II.) ICHIRO IITAKA. *Tetsu-to-Hagané* (*J. Iron and Steel Inst. Japan*) **16**, 1056–63 (1930).—Metals of the alkali and alk. earth groups undergo hydrolysis in acids of concn. less than 10^{-3} *N*, instead of forming salts of the acid. The present paper deals with Mg in dil. HCl, the Cl^- concn. of which is kept at 10^{-2} *N*. The concn. of H^+ was varied from 0 to 10^{-13}. Conclusions: The reaction velocity diminishes with diminution of H^+, but does not vanish when H^+ becomes 0. The velocity remains const. between H^+ = 10^{-4} and 10^{-11}, being independent of H^+. Therefore, hydrolysis must take place here, too, though some replacement of H^+ by metallic Mg occurs, especially when the soln. is stirred. The stirring effect is explained by auto-catalytic action, forming an unknown compd. between Mg, H_2O and Cl^-. Cf. *C. A.* **25**, 863. M. KURODA

The study of chemical reactions from potential-energy diagrams. AXEL R. OLSON. *Trans. Faraday Soc.* **27**, 69–76(1931).—Potential-energy diagrams for *cis-trans* isomers are used to predict the effect of temp., pressure, solvents and light frequency on the stability. ARTHUR FLEISCHER

The decomposition tension of anhydrous uranyl nitrate and of anhydrous thorium nitrate. P. MISCIATELLI. *Gazz. chim. ital.* **60**, 882–5(1930).—Anhyd. $UO_2(NO_3)_2$ was prepd., not by the method of Markétos (*Bull. soc. chim.* **11**, 244(1912); *C. A.* **6**, 3376) or of de Forcrand (*C. A.* **9**, 1882) but by treating $UO_2(NO_3)_2.6H_2O$ with liquid N_2O_5 by the procedure used by Guntz and Martin with $Mn(NO_3)_2$ and $Cu(NO_3)_2$ (cf. *C. A.* **4**, 427). The *app.* is described and illustrated. According to the literature pure anhyd. $Th(NO_3)_4$ has not been prepd. heretofore except in an expt. by Kolb, which could not be repeated (cf. *C. A.* **8**, 306). In the present work, a product contg. only 0.6% excess N_2O_5 and no H_2O was obtained. The tensions corresponding to the equil.:

$Th(NO_3)_4 \rightleftharpoons ThO_2 + 4NO_2 + O_2$ and $2UO_2(NO_3)_2 \rightleftharpoons 2UO_3 + 4NO_2$ were measured by the dynamic compensation method of Centnerszwer and Krustinson (*C. A.* **21**, 689; Crustinson, *Acta Univ. Latviensis* **17**, 665(1928)). Following are the temps. and the pressures (mm. of Hg), resp.: $UO_2(NO_3)_2$, 87°, 95; 131°, 157; 141°, 119; 150°, 340; 160°, 540; $Th(NO_3)_4$, 124°, 82; 134°, 119; 145°, 119; 161°, 359. The same results were obtained with partially decompd. nitrates and with those contg. only 4% N_2O_5. Therefore in this thermal decompn., basic salts are not formed and 2 phases are present in the systems at equil., *viz.*, anhyd. nitrate and oxide. From the decompn. tensions the heats of decompn. can be calcd. by the approx. formula of Nernst. For $UO_2(NO_3)_2$, Q has a mean value of 39,442 and for $Th(NO_3)_4$ a mean value of 81,828. C. C. DAVIS

Reduction of nitric acid by nitric oxide. I. Equilibrium. HANS BODE. *Z. anorg. allgem. Chem.* **195**, 195–200(1931).—The equil. const. for the reaction $H^+ + NO_3^- + 2NO + H_2O \rightleftharpoons 3HNO_2$ was detd. by measuring the pressure of NO above the system. Activities of the HNO_3 are considered. Av. results: K_{298}, 29.4; K_{308}, 50.8; K_{318}, 80.1. **II. Electrochemical potential.** *Ibid* 201–6.—Measurements of the e. m. f. of the equil. system, HNO_3–HNO_2–NO gives as the normal potential for the reaction $NO + NO_3^- \rightleftharpoons 2NO_2^- + \oplus$, 0.517 ± 0.003 v. and for the reaction $NO + 2H_2O \rightleftharpoons NO_3^- + 4H^+ + 3\oplus$, 0.960 v. WILLIAM E. VAUGHAN

What are chain reactions? R. H. CRIST. *J. Chem. Education* **8**, 504–9(1931).—Consecutive reactions that repeat their cycle many times after being initiated are called chain reactions. Several examples are given, such as the reactions between H_2 and O_2, the formation of HCl from H_2 and Cl_2 and the thermal and photochem. formation of HBr. These require an initial process yielding an "active" substance that proceeds through a set of individually known or assumed consecutive reactions to the regeneration of the active product, which repeats the process. The termination of a chain occurs when one of the components of the set is removed permanently or suffers an energy loss sufficient to prevent its continued reaction. In case the number of chains initiated per unit time is greater than the no. of those terminated the reaction may increase to explosive proportions. Chains may be initiated by a variety of methods, photochem., particle and electron collisions, and chem. The photochem. equivalence law affords a means of estg. the number of chains started. R. H. CARTER

A pressure stabilization process for crystalline hydrates. MAURICE AUMERAS. *Compt. rend.* **192**, 229–31(1931).—The equil. conditions under which $Na_2SO_4.10H_2O$ can be kept in hydrated state for an indefinite period of time were investigated. This hydrate can be maintained in a desiccator contg. H_2SO_4, provided the concn. of the H_2SO_4 is such that its vapor pressure is between that of a satd. soln. of Na_2SO_4 and the dissocn. pressure of the hydrate $Na_2SO_4.10H_2O$. Below 30° variations in temp. do not affect the hydrated state of the Na salt. 24.26% H_2SO_4 is the optimum concn. M. MCMAHON

The dissociation of mercuric halides. H. BRAUNE AND S. KNOKE. *Z. physik. Chem.* **152**, 409–31(1931).—The dissocn. of HgI_2, $HgBr_2$ and $HgCl_2$ was measured over a wide temp. range. Heats of formation from the equil. measurements were compared with the calorimeter detns. and were found to agree well. By comparing the measurements with theoretical calcns. of the equil., the moment of inertia of the halides was detd. On the basis of fixed assumptions as to sp. heat, values were obtained which for HgI_2, $HgBr_2$ and $HgCl_2$ are in the proportion 1:0.48:0.22, which is in close agreement with data estd. from gas kinetic data. The app. used is similar to that used with NH_4Cl (*C. A.* **22**, 3570). M. MCMAHON

Statistical treatment of reaction-velocity data. I. Critical review of current methods of computation. LOWELL J. REED AND EMERY J. THERIAULT. *J. Phys. Chem.* **35**, 673–89(1931).—The usual methods of computing rate consts. is reviewed Unimolecularity of rate cannot be tested by the consistency of a series of K values The least-squares procedures described in chem. literature are not applicable to unimolecular data. Systems of weighting unimolecular const. are inapplicable in presence of const. errors. S. LENHER

The solution velocity of oxygen in water. IV. SUSUMU MIYAMOTO AND AKIRA NAKATA. *Bull. Chem. Soc. Japan* **6**, 9–22(1931); cf. *C. A.* **25**, 635.—O_2 gas was passed into a stirred vessel contg. Na_2SO_3 soln. The rate of oxidation of the Na_2SO_3 was independent of the concn. of the Na_2SO_3 and dependent only on the surface area exposed and the temp. (The rate of stirring was const. and only pure O_2 was used.) The theory is proposed that only those mols. of O_2 dissolve whose component of velocity normal to the surface is greater than a threshold value about 3.4 times the root mean square velocity. T. H. CHILTON

Kinetics of heterogeneous formate formation. GUSTAW BIRSTEIN AND NIKOLAUS

LOBANOW. *Z. anorg. allgem. Chem.* **195**, 173–94(1931).—The rate of reaction between aq. HCHO solns. and NaOH in equiv. amts. in the presence of CuO was measured at temps. of 0° and 20°. The total reaction is as follows: $HCHO + NaOH + {}^1/_2CuO \longrightarrow {}^1/_2Cu + HCOONa + {}^1/_2H_2 + {}^1/_2H_2O$. In the presence of CuO the reaction is autocatalytic. An induction period of 20 to 70 min. was noted; the variation depends upon temp. and concn. The reaction apparently is an absorption process, which depends upon the surface of the catalyst. When there are equiv. amts. of HCHO and NaOH the reaction obeys the equation $dx'/dt = ka'^{1/2}x'(1 - x')^{1/2}$. Temp. coeffs. were detd. When either HCHO or NaOH is present in excess, the reaction follows the equation $dx'/dt = kax'(1 - x')$. WILLIAM E. VAUGHAN

Rates of intramolecular change between ammonium thiocyanate and thiourea. WM. URE AND T. BENTLEY EDWARDS. *Trans. Roy. Soc. Can.* [3], **24**, Sect. 3, 153–9 (1930).—The reaction $NH_4SCN \rightleftharpoons CS(NH_2)_2$ in ethylene glycol was studied at 178.8° and 184.3° and over a 5-fold range in concn. The reaction is not as simple in the presence of solvent as it is in its absence. Complicating side reactions are indicated by the fact that the value of K representing the ratio $\frac{CS(NH_2)_2}{NH_4SCN}$ does not remain const. at const. temp but decreases with decreasing total concn. J. W. SHIPLEY

Effect of sodium salts of monohydroxy acids on the rate of saponification of methyl acetate by sodium hydroxide. F. L. ALLEN. *Trans. Faraday Soc.* **26**, 527–33(1930).—The hydrolysis of AcOMe in 0.0125 *N* soln. by NaOH at 20° is markedly retarded by Na salicylate at a concn. of 0.1 *N* or even 0.05 *N*, and Na glycolate, mandelate, lactate, β-hydroxy-β-phenylpropionate and α-hydroxy-β-phenylpropionate at a concn. of 0.1 *N* have a similar, but much less pronounced, effect. The position of the OH and Ph groups in the salt mol. bears little relation to its retarding action, which is ascribed to the formation of H ions by ionization of the OH group. By means of this assumption the dissocn. const. of the OH group can be calcd. from the velocity data, the neutral salt effect apparently being small. B. C. A.

The complexity of sulfur trioxide. A. SMITS. *Z. physik. Chem.* **152**, 432–50 (1931).—Previous results of investigation of the SO_3 system (*C. A.* **19**, 1213; **20**, 3107) are reviewed in detail. There are 3 solid phases α, β and γ; the α and β modifications are metastable and the γ modification is stable. It was shown experimentally that the α and γ modifications are mixed crystals of pseudo-components. The mixed crystals of γ form behave like a mixt. The α modification, in extremely dry state, behaves somewhat like the γ modification. X-rays show not only the inner equilibrium but also the change from metastable form to stable modification. M. MCMAHON

An allotropic transformation of calcium in the solid state. E. RINCK. *Compt. rend.* **192**, 421–3(1931).—Heating and cooling curves for Ca exhibit a horizontal portion that reveals a point of transition between 2 solid forms of Ca. Below 450° the stable form is α-Ca; between 450° and the m. p. at 848° the stable form is β-Ca. The curve of elec. resistance *vs.* temp. exhibits a break at 450°. The change from β- to α-Ca involves contraction in vol. Attempts to retain β-Ca at room temp. by rapid cooling were unsuccessful. F. L. BROWNE

Investigation of the system: bismuth–selenium. N. PARRAVANO AND V. CAGLIOTI. *Gazz. chim. ital.* **60**, 923–33(1930).—Thermal analysis and micrographic studies of the system: Bi–Se, have already proved the existence of Bi_2Se_3 and BiSe (cf. *C. A.* **7**, 3103). Since bivalent Bi compds. are not known otherwise, it was of interest to confirm the existence of BiSe by x-ray examn. Alloys from Bi 63.50, Se 36.50 to Bi 89.10, Se 10.82 were studied, as well as Bi and Se themselves. The spectrographs are reproduced and the results are tabulated. For Bi, the lattice const. a_0 is 4.531, which agrees well with the 4.539 value of Davey (cf. *C. A.* **19**, 2891). For Se, the lattice const. is 4.360 (rhombohedric), in good agreement with the 4.379 value of Olshausen (cf. *C. A.* **20**, 131). Prepd. artificially, Bi_2Se_3 differs from the natural product in that it shows trigonal symmetry, with an axial ratio c/a of approx. 1.68. Its a_0 value is 6.702 and 5.382 (rhombohedric), its exptl. d. 7.398 and the nos. of mols. in the hexagonal and rhombohedric cells are 3 and 1, resp. BiSe gave c/a = 1.60, a_0 = 5.021 and 3.846 (rhombohedric) and exptl. d. =7.98, with 3 mols. and 1 mol. in the hexagonal and rhombohedric cells, resp. The röntgenographs of Bi_2Se_3 and BiSe are very similar in the succession, general character and intensity of the interference lines, which suggests similar structures. The closeness of the axial ratios suggests solid solns., *i. e.*, BiSe is the limiting case of a solid soln. of Bi in Bi_2Se_3. Neither hypothesis can, however, be valid, not only because of the thermal analysis and x-ray diagrams, but because BiSe lacks certain interference lines and shows other lines which mark it as a distinct compd. Moreover there is no gradual displacement of the lines in the various alloys, and all of the latter show their 2

spectra superposed. The powder method did not allow a decision as to the similarity of structure of Bi_2Se_3 and BiSe. C. C. DAVIS

The two-component system: iron–vanadium. FRANZ WEVER AND WERNER JELLINGHAUS. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* **12**, 317–22(1930).—The liquidus-solidus curves correspond to those of other investigators, showing a min. at 1468° with 31% V. The α-mixed crystals from 0° to 100% V are cubic centered with lattice parameters that increase from 2.86×10^{-8} cm. for 0 atom % V to 2.89×10^{-8} for 50 atom % and 3.04×10^{-8} for 100 atm. %, thus departing from Vegard's law. The γ-Fe field is bounded by a closed curve beginning at 1400° extending to 1.15% V and 1150° and then back to 900°. The α-mixed crystals are transformed at 1234° to a homogeneous, friable crystal mass that corresponds to FeV. This combination dissolves both Fe and V. The crystals are non-magnetic at room temp. V at first increases the magnetic transformation temp. and then decreases it after passing a max with 17% V, and approaches room temp. with 58% V. H. C. DUUS

Making a three-component liquid-vapor chart. JOHN HAPPEL AND JOHN GRISWOLD. *Chem. Met. Eng.* **38**, 92–3(1931).—An alignment chart is described from which the vapor-liquid equil. relation may be detd. for a 3-component system. A chart for benzene, toluene, and xylene at one atm. is given. L. W. T. CUMMINGS

The system: water–potassium nitrate–calcium nitrate. MOHAMMED ABDUL HAMID AND RAM DAS. *J. Indian Chem. Soc.* **7**, 881–2(1930).—The isotherm was detd. at 25°. The soly. of KNO_3 is 27.30 and that of $Ca(NO_3)_2$ 57.98 g. per 100 g. soln. O. T. Q.

The acid-basic-catalysis according to J. N. Brønsted. I. M. KOLTHOFF. *Chem. Weekblad* **28**, 110–21(1930); cf. *C. A.* **24**, 3697.—A review. E. SCHOTTE

Thermal dissociation. J. KRUSTINSONS. *Acta Univ. Latviensis Kim. Fakultat Serija* **1**, Fasc. 1, Burtnica, (in German, 63), (in Lettish 29–62)(1929).—Dissocn. phenomena of Tl_2CO_3, $LiNO_3$, $NaNO_3$, KNO_3, $RbNO_3$ and $CsNO_3$ are discussed. The isochores of liquid compds. between 200 and 900 mm. approach a straight line. Single compds. with a common ion dissolved in Tl_2CO_3 show a mol. raising of the dissocn. temp. Nitrates dissolved in the corresponding nitrite show a strong initial rise. Binary mixts. of unlimited soly. show a min. dissocn. temp. dependent upon the mol. compn.

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

W. ALBERT NOYES, JR.

Recent advances in science: physics. L. F. BATES. *Science Progress* **25**, 383–9 (1931).—A review is given of recent work on α-particles, ionic mobilities and related subjects. JOSEPH S. HEPBURN

Analytic atomic wave functions. C. ZENER. *Phys. Rev.* **36**, 51–6(1930).—Math. BERNARD LEWIS

The specific charge of the electron according to wave mechanics. FRITZ SAUTER. *Naturwissenschaften* **19**, 165–6(1931).—The suggestion of Page (*C. A.* **24**, 5602; *Phys. Rev.* **36**, 1418(1930)) explaining on the basis of wave mechanics the difference between spectroscopic and magnetic values of e/m is erroneous (cf. also Eckart, *Phys. Rev.* **36**, 1014, 1514(1930); Uhlenbeck and Young, *Phys. Rev.* **36**, 1721(1930)) B. J. C. VAN DER HOEVEN

Interaction between excited and unexcited hydrogen atoms at large distances. E. C. KEMBLE AND F. F. RIEKE. *Phys. Rev.* **36**, 153–4(1930).—Quantum mech. calcns. on the energy of different quantum states are given. The exact first-order computations of Kemble and Zener (*C. A.* **23**, 4878) are extended to internuclear distances R = 5, 6, 7, 10. BERNARD LEWIS

Calculation of energy values. C. ECKART. *Phys. Rev.* **36**, 149–50(1930).—Calcd. by a modification of the Ritz method for characteristic nos. in quantum dynamical problems, the results are given for the $2P$ and $3D$ states. BERNARD LEWIS

Physical and chemical principles that underlie the interpretation of novae. A. C. GIFFORD. *Scientia* **49**, 169–82(1931).—A crit. review of existing theories of the formation of novae. G. finds the only satisfactory explanation to be that they arise from the grazing collision of 2 stars. J. B. AUSTIN

Stellar structure. F. A. LINDEMANN. *Nature* **127**, 269(1931).—The assumption of a temp. of mc^2/k in the inside of a star is not necessary to explain the generation of energy by the annihilation of matter. In stars the important factor is the rate at which protons and electrons disappear as radiation. If an equil. state is attained matter can be annihilated in stars with interiors at temps. of 1.1×10^{13}°. A. F.

A new measurement of the temperature in the arc. ALFRED V. ENGEL AND MAX STEENBECK. *Naturwissenschaften* **19**, 212–3(1931).—By detn. of the weakening of an x-ray passing through hot arc gases the d. of the gas and hence its temp. for known pressure is calcd. The x-ray intensity decreases for density δ by $I/I_0 = e^{-al\delta}$ for α the (known) absorption coeff. and l the electrode distance. For air at atm. pressure the measurements were made with 1600 to 3300 v., 1 ma., Cu anode, x-radiation filtered through 7μ Al and passed through a 1.5-mm. hole in the water-cooled Cu electrode of the arc. Through an aperture in the other arc electrode the x-ray reaches a Geiger point counter (p = 100 mm. Hg). The d. c. arc with stabilization was rectilinear inside a 5-cm. glass tube. The gas d. was found by measuring the no. of counter impulses on evacuating the cold arc tube and recording the d. at which the no. of impulses equaled that from the hot arc. With proper corrections for edge effects, etc., was found from 45,000 counted impulses a gas temp. of the 2-amp. air arc of 5250° abs. (±300°). A measurement by the carbon pencil method in the middle of the arc gave 3100° abs. The former figure is considered to be better. B. J. C. V. D. H.

A charge exchange effect during the passage of protons through helium. R. DÖPEL. *Naturwissenschaften* **19**, 179–80(1931).—A study of the passage of H canal rays through He revealed a charge exchange effect. The canal ray is deviated by passing through condensers K_1 and K_2 and subsequently its energy is measured. For a no. of protons n_1 at K_1, n_2 at K_2 will hold $n_2 = n_1 e^{-\alpha a}$ with α a measure for the active radius for charge exchange, a the condenser distance. It is assumed that the He pressure is low enough to prevent repeated charge exchanges of the neutral atoms between K_1 and K_2. The active radius α has been detd. as a function of the proton

velocity v. α increases with decreasing v and decreases again after reaching a max. at about 10^8 cm. per sec. (analogous to the Ramsauer effect). B. J. C. v. D. H.

Mobility of sodium ions in hydrogen. L. B. LOEB. *Phys. Rev.* **36**, 152–3(1930).—The mobilities of Na^+ ions were measured in purified H_2. It is found that within 2×10^{-8} sec. after their liberation the ions have more than twice the mobility of the normal ions. BERNARD LEWIS

Electron diffraction. F. KIRCHNER. *Physik. Z.* **31**, 1025–8(1930); cf. *C. A* **24**, 5602.—Electron diffraction patterns are sharper than x-ray patterns, because the nucleus governs the scattering of electrons, and the electrons affect the scattering of x-rays. In electron diffraction patterns the 2nd-order spectra due to the (111) planes of NaF are not entirely extinguished, since the nuclear charges of Na^+ and F^- are unequal. Debye-Scherrer diagrams due to electrons diffracted by comparatively large crystals sometimes show interference points at the ends of a diam. of one or more of the rings. These can be ascribed to a mosaic-like structure of the crystal. Sublimation under vacuum of $HgCl_2$ from a heated Pt strip to a celluloid surface gives a cubic instead of a rhombic crystal. Diffraction by gaseous N, O or CO_2 gave patterns in accord with Debye x-ray patterns. A. L. HENNE

Electron diffraction and molecular structure. R. WIERL. *Physik. Z.* **31**, 1028 (1930).—This is a detn. of the distance between at. nuclei in a mol. as measured by electron diffraction. In CS_2, the distance S-S is 3.20 A. U.; in CO_2, O-O is 2.26 A. U., in N_2O, N-N is 2.38 A. U.; in SO_2, the distance S-O is doubtful, on account of the triangular shape of the mol.; the value 1.37 A. U. is proposed. A. L. HENNE

Emission of electrons caused by an electric field when the surface of a metal is exposed to the light. L. ROZENKEVICH. *J. Russ. Phys.-Chem. Soc.*, Phys. Pt., 62, 229–30(1930).—It is pointed out that a study of the emission of electrons caused by an elec. field when a metal is exposed to the light may lead to a new conception of electronic energy. V. VESSELOVSKY

The photoelectric effect from sodium chloride in various gases. N. GUDRIS AND L. KULIKOVA. *J. Russ. Phys.-Chem. Soc.*, Phys. Pt., 62, 247–50(1930).—The photoelec effect from dielectrics is highly stimulated by the presence of the vapors with high dielec consts. in the vicinity of the surface investigated. It seems that the mols. of such gases having a high dipolar moment may disengage ions from the surface of the crystal. When the vapors dissolve the crystal (water vapor) this can also take place inside the lattice, which would also increase the intensity of the photoelec. current. In the other gases the photoelec. effect is similar to that in air. V. VESSELOVSKY

Photoelectric effect and electron reflection at hydrogenated potassium surfaces W. KLUGE AND E. RUPP. *Physik. Z.* **32**, 163–72(1931).—An app. is described which permits photoelec. and electron-reflection measurements to be made on the same K surface. The surfaces studied were: pure K, K in H_2 atm. (I), K subjected to weak glow discharge in H_2 (II), and K subjected to strong glow discharge in H_2 (III). The colors of these layers were: K, metallic; I, metallic; II, reddish violet; and III, greenish With the pure K surface, the voltages causing max. electron reflection corresponded to planes in the K lattice only. With I only electron-reflection max. for KH were observed. With II and III max. for both K and KH were observed, those for KH predominating in the case of II. In all cases the photoelec. effect showed a pronounced max. in the region 4000–4500 A. U. This "selective" effect increased in the order K, I, III, II. The electron-reflection max. led to a value 7.3 v. for the inner potential of K and 5.4 A. U. for the lattice const. of KH (assumed cubic). O. T. Q

A thermal theory of cathodic disintegration. H. P. WARAN. *Phil. Mag.* [7], 11, 397–404(1931); cf. *C. A.* **16**, 1043; **17**, 3643.—The sputtering of cathodes is due to the evapn. of small masses of metal under localized intense heat due to proton bombardment. The observed relative sputtering of various metals agrees qualitatively with those expected from the thermal conductivities of the metal and gas surrounding the cathode, the sp. heat of the metal and the gas, the gas pressure, metal d., b. p. and latent heat of the metal. ARTHUR FLEISCHER

Measurement of capacity for reflection of glowing tungsten in the ultra-violet part of the spectrum. E. SPILLER. *Z. Physik* **64**, 39–42(1930).—The relative intensities of emission at different wave lengths from a lamp with a W filament heated to 2873° abs. were found, a special microphotometer being used. The emission departs from blackbody radiation. The energy distribution was measured over a wave-length range of 400–340 mμ. The values of the emission coeff. for wave lengths from 436 to 270 mμ for a filament at 2100° abs. are tabulated. B. C. A.

Photo-ionization of salt vapors. A. TERENIN. *Phys. Rev.* **36**, 147–8(1930).—The photo-ionization of the halides of Th was investigated with wave lengths longer than

1850 A. U. The ionization and dissocn. energies and the stability of the neutral and the ionized mol. are discussed. The photo-ionization decreases from the iodide to the chloride. BERNARD LEWIS

A theory of the arrangement of protons and electrons in the atomic nucleus. WENDELL M. LATIMER. *J. Am. Chem. Soc.* **53**, 981–90(1931).—A model of the nucleus is proposed in which the protons and electrons are held in a definite space lattice. Because the most stable nuclei contain 4, 7, 10, 12 and 14 α-particles, L. suggests a tetrahedral arrangement of these α-particles, which themselves are considered to be tetrahedral arrangements of 4 protons about an electron pair. This model satisfies the requirements of quantum mechanics for vector combination. E. J. ROSENBAUM

Theory of the emission of electrons by α-particles. H. C. BRINKMAN AND H. A. KRAMERS. *Proc. Acad. Sci. Amsterdam* **33**, 973–84(1930).—Math. G. M. E.

Pleochroic "giant" halos in cordierite. M. S. KRISHNAN AND C. MAHADEVAN. *Indian J. Physics* **5**, 669–80(1930).—Several "giant" halos having radii 0.050 and 0.063 mm., which are larger than those for normal-range α-particles, were found in a cordierite-gneiss from Madura. These large rings are ascribed to long-range α-particles from Ra C′ and Th C′ which have a theoretical penetration in cordierite of 0.052 and 0.064 mm., resp. J. B. AUSTIN

The content of radium in oil-well waters in the district of Grozny. V. G. KHLOPIN AND B. A. NIKITIN. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, 393–8.—The authors give a detailed analysis of the Ra content of the oil-well waters of the district of Grozny. The waters have a very high content of Ra, which indicates a possibility of obtaining Ra from this source on a com. scale. L. JACOVLEFF

The radioactivity of oil-well waters. V. I. VERNADSKII. *Compt. rend. acad. sci. U. R. S. S.* **1930 A**, 399–401.—The content of Ra in the oil-well waters of the district of Grozny reaches 1.2×10^{-8}%. V. discusses the possible origin of the Ra and concludes that the origin of Ra in this district is due to biochem. processes. L. JACOVLEFF

Modification of quanta by photo-ionization. S. BHARGAVA AND J. B. MUKERJIE. *Nature* **127**, 273(1931); cf. B. B. Ray, *C. A.* **24**, 3705, 4213, 5608.—The spectrum of Cu $K\alpha_1$, α_2 radiation after passing through 1 mm. thickness of paraffin showed a modified line on the long wave length side sepd. by the approx. distance $\Delta\nu = R$. The quantum may on its passage through at. shells impart any part of its energy to the electron from $h\nu_k$ to $h\nu$ and be modified from ν to the frequency range $\nu - \nu_k$ to zero. *Ibid* 305.—The emergent ray from Ag $K\alpha$ radiation passed through 0.06 mm. thickness of Ni foil showed a modified band at $\nu/R = 1019.7$. The ν/R of Ag $K\alpha$ radiation minus the ν/R of the expt. is 612.9, which checks Siegbahn's value of 612 for Ni. This supports the view that quanta are modified as previously described. A. F.

Raman lines in x-ray spectra. GEO. A. LINDSAY. *Nature* **127**, 305(1931); cf. preceding abstr.—Displacement of Cu K lines on passing through graphite and amorphous C, as reported by the preceding investigators, could not be reproduced. ARTHUR FLEISCHER

The most penetrating component of cosmic radiation (Hess radiation). E. REGENER. *Naturwissenschaften* **19**, 177–9(1931).—Data are given on cosmic-radiation measurements under water (*C. A.* **23**, 2648). B. J. C. VAN DER HOEVEN

Breadth of Compton modified line. J. W. M. DUMOND. *Phys. Rev.* **36**, 146–7 (1930). BERNARD LEWIS

Spectral lines obtained by the method of convergent x-rays. T. FUJIWARA. *Mem. Coll. Sci. Kyoto Imp. Univ.* **13A**, 303–6(1930); cf. *C. A.* **23**, 1811.—A detailed study of the spectral lines produced by fine single-crystal wire is presented. B. C. A.

X-ray structure investigations. SCHIEBOLD AND H. REININGER. *Giesserei-Ztg.* **26**, 634–41, 666–72(1929).—The production and characteristic properties of x-rays and their application to structure analysis are reviewed. MALCOLM DOLE

The lattice distance and the reflecting power for x-rays of bismuth relative to the cleavage planes. E. ADINOLFI. *Rend. accad. sci. Napoli* [3], **36**, 69–75(1930).—A new procedure is described for detg. the lattice distances of crystals by Bragg's method. Direct comparison is made with the lattice distance of calcite relative to the (100) planes, which has been taken as the basis for spectrometric measurements. By this procedure the lattice distance for Bi atoms in (111) planes was detd. to be 3.970 A. U. The structure factor of calcite is const., whereas that of Bi, for the same range of frequencies, increases with diminishing wave length of the radiation used. This indicates that increasing the frequency increases the no. of electrons of Bi which participate in the phenomenon of reflection. This method of the direct comparison of 2 crystals results in increased precision, in detection of parasitic lines and in greater exactness

in the study of the relative reflecting power of the 2 crystals in a given spectral region. R. H. LOMBARD

The construction of an experimental x-ray tube to furnish the homogeneous *K* radiations of uranium. WARNFORD MOPPETT. *J. Cancer Research Comm. Univ. Sidney* **2**, 147–52(1930).—Constructional details of the app. are given and the method of operating it is described. G. SCHWOCH

Partial absorption of x-rays. B. B. RAY. *Z. Physik* **66**, 261–8(1930).—The Compton effect is studied by means of CuK_α, NiK_α, Ni$K_{\beta 1}$, W$K_{\alpha 1}$ and Fe$K_{\beta 1}$ radiation sent through C, N and O. A possible mechanism for the Raman effect is worked out at some length. GREGG M. EVANS

The paramagnetism of polychromates. FRANCIS W. GRAY AND JOHN DAKERS. *Phil. Mag.* [7], **11**, 297–314(1931); cf. *C. A.* **24**, 5613.—The mol. susceptibilities were detd. in the app. of Gray and Dakers (cf. *Phil. Mag.* [7], **9**, 81). The values ($\times 10^6$) are K_2CrO_4 0.0, $K_2Cr_2O_7$ + 54.0, $K_2Cr_3O_{10}$ + 95.0, $K_2Cr_4O_{13}$ + 193.0, CrO_3 + 41, Na_2CrO_4 + 19.4. The av. susceptibility of CrO_3 in solns. with 1 mol. CrO_3 to from 39.27 to 18.89 mols. H_2O was +0.39. A small paramagnetism due to the interchange of electrons and consequent fluctuations of angular momentum gave the best interpretation of the exptl. results. ARTHUR FLEISCHER

A synchronous film drum for recording periodic spectra. DONALD C. STOCKBARGER AND CARL G. SELIG. *Rev. Sci. Instruments* **2**, 211–6(1931). E. H.

Studies in peculiar stellar spectra. I. The manganese lines in α Andromedae. W. W. MORGAN. *Astrophys. J.* **73**, 104–17(1931).—The spectrum of α Andromedae is of Class A_0p, the peculiarity being due to the presence of many lines of ionized Mn. An examn. at the Yerkes Observatory of spectrograms of stars belonging to Classes B_8 to A_0 has revealed the presence of enhanced Mn lines in 13 other stars. The lines probably belong to Mn III, indicating that the element is present in the 2nd stage of ionization. If the high abs. magnitudes of these stars are taken into consideration the presence of enhanced Mn lines seems to be a normal feature of their spectra, the lines reaching their max. in stars of Class B_9. C. C. KIESS

Influence of an inhomogeneous electrical field upon the fine structure of hydrogen-like atoms. SISIRENDU GUPTA. *Z. Physik* **66**, 246–56(1930).—The frequencies and intensities of the lines for the inhomogeneous Stark effect are derived math. and the sepn. is found to be of the order of 0.001 A. U., even for a field gradient of 10^6–10^7. This sepn. is so small as to be discernible only as a slight broadening of the lines. GREGG M. EVANS

The radiation emitted by compressed substances under high potentials. ISAY A BALINKIN. *Phil. Mag.* [7], **11**, 315–22(1931); cf. Reboul, *C. A.* **21**, 20.—The expts of Reboul were repeated for compressed potash alum, NaCl and other powders. The factors controlling the emission were the applied potential, relative humidity, size of cryst. grains and the pressure used in compressing the powders. The very absorbable radiation is due to the escape of air from the bottom of the cell and belongs to the same class as "Entladungsstrahlen." ARTHUR FLEISCHER

Experimental evidence for the existence of quadripole radiation. R. FRERICHS AND J. S. CAMPBELL. *Phys. Rev.* **36**, 151–2(1930).—The green auroral line at 5577 A. U. was found to be resolved into 4 components by means of the Zeeman effect. This indicates that the line is quadripole radiation. BERNARD LEWIS

Regularities in the second spectrum of xenon. C. J. HUMPHREYS, T. L. DE BRUIN AND W. F. MEGGERS. *Bur. Standards J. Research* **6**, 287–93(1931).—The ground doublet ($^2P°_{1/2}$, $_{3/2}$) in the spectrum of ionized Xe (Xe II) has been identified; the levels are sepd. by 10,540 wave nos. This spectral term has been connected with others which combine so as to give most of the intense lines in the visible Xe II spectrum. The abs. values of the terms have been fixed by extrapolating series-forming terms to their limits, and from these spectroscopic data the ionization potential of Xe^+ is found to be about 21.1 v. W. F. MEGGERS

A study of stellar hydrogen lines and their relation to the Stark effect. C. T ELVEY AND O. STRUVE. *Astrophys. J.* **72**, 277–300(1930); cf. *C. A.* **24**, 3950.—The contours of the H absorption lines in early-type stars have been detd. from microphotometer measurements of stellar spectrograms. The lines exhibit extensive wings which are evidence for the existence of a Stark effect. The theoretical contour of a line subject to an elec. field in an atm. in which the pressure increases with depth is detd. and is found to be very similar to those actually observed. C. C. KIESS

Probabilities of recombination into the 1^2S state of cesium. C. BOECKNER. *Bur Standards J. Research* **6**, 277–85(1931).—Measurements are made of the intensity distribution in the continuous emission band, appearing at the 1^2S series limit of Cs, a

low-voltage thermionic discharge in the vapor is used as a source. The wave-length range covered lies between the series limit 3184 A. U. and about 2750 A. U. The methods of photographic densitometry are employed, a W-strip lamp in quartz being used as a comparison source. From the variation of intensity with wave length and the velocity distribution of the discharge electrons are computed the relative probabilities of recombination of free electrons into the 1^2S state as a function of their initial velocities. Previous work has shown that the probability of recombination into the 2^2P and 3^2D states of Cs varies approx. inversely as the square of the velocity of the free electron, a relation which is also predicted by quantum mechanics for recombination into any level of a H atom. The present measurements show that the probability of recombination into the 1^2S Cs level falls off much more rapidly with the velocity; for electron energies greater than 0.15 v., more nearly as the inverse 4th power. W. F. M.

Structure of the iron spectrum. M. A. CATALÁN. *Anales soc. españ. fís. quím.* **28**, 1239–385(1930).—Previous data on the at. structure of Fe are summarized and new advances given. More than 2350 lines are classified in the spectrum of Fe I, in 304 levels. The most intense lines originate by addn. of a valence electron to the at. residue in one or both spark configurations $3d^64s$ and $3d^7$. Lines produced by a double jump are frequently intense. E. M. SYMMES

The raies ultimes in the arc spectrum of rhenium. HERBERT SCHOBER AND JOSEF BIRKE. *Naturwissenschaften* **19**, 211–2(1931).—The raies ultimes of the Re arc spectrum as observed from varying concns. of Re salt on C, *i. e.*, those lines that originally have the largest intensity, are at 3452.02, 3460.61 and 3464.87 A. U. Intensity and wave length are given for 23 other Re lines. B. J. C. VAN DER HOEVEN

Resonance radiation of manganese vapor. J. FRIDRICHSON. *Z. Physik* **64**, 43–7 (1930).—The fluorescence in satd. Mn vapor at 700–900° was examd., the light of the Mn spark being used for excitation. The triplets $1S-2P$ and $1S-2P'$ of the Mn spectrum correspond with the resonance lines. With rise of temp., and consequently less dense vapor, the triplet $1S-2P'$ becomes much more intense, whereas at a lower temp. only the triplet $1S-2P$ is found. The resonance lines found are in agreement with Catalan's analysis (*C. A.* **17**, 1586; **22**, 1901) of the Mn spectrum and indicate that $1S$ is the lowest state of the Mn atom. B. C. A.

Spectrum of the tungsten mercury arc. W. E. FORSYTHE AND M. A. EASLEY. *Phys. Rev.* **36**, 150–1(1930).—The pressure of Hg vapor in a Hg arc lamp is increased by external heating between W electrodes and the effect on the absorption bands in the region 2100–4000 A. U. is described. The absorption spectrum is compared with that of Hg in another quartz absorption cell. BERNARD LEWIS

Note on the spark spectra of chlorine. KIYOSHI MURAKAWA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, 105–9(1931).—About 30 lines between 2469 A. U. and 4695 A. U. are classified as members of the quartet system of Cl III. A few corrections and extensions of the analysis of Cl II, previously reported (*C. A.* **25**, 1157), are noted. C. C. KIESS

Spectrum of doubly ionized iodine. J. B. SETH. *Nature* **127**, 165(1931).—A short table is given of some new measurements on doubly ionized I in the visible and the ultra-violet regions. MALCOLM DOLE

Temperature classification of the stronger lines of columbium, with preliminary notes on their hyperfine structure. ARTHUR S. KING. *Astrophys. J.* **73**, 13–25(1931).—The spectra of Cb, as excited in arcs and in spark discharges, and in the vacuum elec. furnace at temps. ranging from 2500° to 2900°, were examd. in the region from 3094 A. U. in the ultra-violet to 6918 A. U. in the red. Temp. classifications have been detd. for 646 lines in this interval, of which approx. 200 appear with furnace excitation. The others, consisting of lines of both the neutral and ionized atoms, require the higher excitation energy of the arc and spark for their appearance. About 40% of the lines examd. are complex, the hyperfine structure consisting of 2, 4, 6, and in some cases, more components. C. C. KIESS

Calorimetric and electric measurements in the mercury arc. JÓZEF KAWA. *Sprawozdania i Prace Polski. Towarzystwa Fiz.* **4**, 27–58; *Chem. Zentr.* **1929, II**, 2979.—The Fe anode of a Hg-arc lamp of Pyrex glass was constructed in such a way as to serve as a calorimetric vessel, which was filled with H_2O. The Hg cathode and the glass wall of the lamp up to the anode were immersed in water in order to obtain const. temp. and const. Hg-vapor tension during the arcing period. The calorimetric measurements carried out with various c. ds. and arc lengths gave the following results with regard to the mechanism of the Hg arc. Ionization occurs in the 1st part of the pos. column on account of the greater field strength. The pos. and the neg. space charges are formed. Between these originates a reverse elec. field which brakes the speed of

the electrons accelerated in the 1st part of the column. Because of this also the heat formation at the anode is diminished. Between the pos. space charge at the front of the pos. column and the neg. space charge in the Faraday dark space an increased pos. field strength is developed. With further increase of the arc length, under suitable conditions, there occurs a 2nd max. These results are supported by spectroscopic investigations. The arc was mixed with some He, whose lines appear only in places of higher field strength on account of the higher excitation potential. G. SCHWOCH

Different spark spectra of mercury. R. RICARD. *Compt. rend.* **192**, 618–20 (1931).—A no. of new lines have been found in the spectrum of the electrodeless discharge in Hg. These lines fall into the 3 spectra, Hg II, Hg III and Hg IV. A no. of these lines in the Hg II spectrum can be interpreted by admitting the existence of doublets and quadruplets. J. R. ADAMS

Influence of pressure and temperature of added neon on the absorption in excited mercury vapor. OSAMU MASAKI. *Z. Physik* **66**, 229–40(1930).—Ne purified by passing over liquid air and through discharge tubes with Mg electrodes was circulated through an emission and an absorption tube contg. Hg excited by 10 ma. at 8000 v. The beam from the emission tube was split, one beam passed through the absorption tube, reunited in a spectrophotometer, and the absorption measured. The $2^3P_{0,1,2}$–2^3S transitions were studied. The absorption of lines 4047 and 5461 A. U. diminishes slightly with increasing pressure; 4358 shows a slight increase. A satn. is shown with increase in temp., 4358 and 4047 increasing toward about the same value, while 5461 decreases to reach a satn. value slightly under that of the others. GREGG M. EVANS

The crystal structure of parahydrogen at liquid-helium temperatures. W. H. KEESOM, J. DE SMEDT AND H. H. MOOY. *Nature* **126**, 757(1930).—See *C. A.* **25**, 873. A. L. HENNE

Spectroscopic isotope determinations. R. SCHMID. *Magyar Chem. Folyóirat* 36, 185–91(1930).—General description of present theory and methods. S. S. DE F.

The interpretation of molecular spectra. V. The excited electron terms of molecules with two equal nuclei (H, He, Li, N, O). F. HUND. *Z. Physik* **63**, 719–51 (1930); cf. *C. A.* **21**, 3310; **23**, 564. W. F. MEGGERS

A new band system of hydrogen and the conditions for its production. Z. BAY, W. FINKELNBURG AND W. STEINER. *Z. physik. Chem.*, Abt. B, **11**, 351–62(1931).—A strong condensed discharge ($^1/_2$ mf. capacity) produces a yellow band group of the many-lined spectrum and a no. of other strong lines, while the remaining many-lined spectrum vanishes. From the variation of intensity with gas concn. in the discharge tube it is concluded that the yellow group belongs to the H_2 mol. The group was not completely analyzed, because the weak lines were missing, but it appears to be 2-band systems with a common initial or final term. This term is not one of the known H_2 terms. The electron jump has the values 2.1 and 2.6 v., which excludes a transition between the 2nd, 3rd and 4th levels. J. B. AUSTIN

Some relationships between the continuous and the many-lined spectrum of hydrogen. I. YOSISIGE HUKUMOTO. *Science Repts. Tôhoku Imp. Univ.* **19**, 773–92 (1931).—The behavior of the H_2 spectrum under different conditions of pressure was observed and the relative intensities were estd. Most of the lines which are enhanced at high pressure when the continuous spectrum is intense are classified as the transitions $3^3\Pi \longrightarrow 2^3\Sigma$, $4^3\Pi \longrightarrow 2^3\Sigma$, etc. These exptl. facts favor the theory that the continuous spectrum arises in the transition from any one of the excited triplet levels to the unquantized ground state $1^3\Sigma$. W. F. MEGGERS

Nitric oxide δ-bands. R. SCHMID. *Z. Physik* **64**, 279–85(1930).—In order to produce the δ-bands of NO in sufficient intensity to be photographed special means of excitation must be used. With a Tesla app. and other devices for special excitation it was found possible to produce the bands in the afterglow in the production of active N mixed with air. The rotation analysis of the band δ(0.3) is given, and the rotation const. of the δ-bands for the $^2\Sigma$ initial level is calcd. to be $B_0 = 1.995$ cm.$^{-1}$. Also in *Matematik. és Természettudományi Értesetö* **47**, 534–42(1930). B. C. A

Nitric oxide β- and γ-bands. R. SCHMID, D. FARKAS AND T. KÖNIG. *Z. Physik* **64**, 84–120(1930).—The NO lines previously measured were classified and ordered. In this way some 3000 γ- and 1000 β-lines were arranged. The rotation and vibration consts. were in some cases calcd. afresh. The doublet splitting of the levels $^2\Pi_i$ was obtained as a function of rotational and vibrational states. The potential-energy curve for NO was obtained, as well as Condon's parabola. Also in *Matematik. és Természettudományi Értesetö* **47**, 485–532(1930). B. C. A

The structure of the spectra of sulfur. Contribution to the study of the relations between spectra of the same multiplicities. M. GILLES. *Ann. Phys.* **15**, 267–408

(1931).—Grating and prism spectrographs were employed to observe the spectra of singly and doubly ionized S from 2089 A. U. in the ultra-violet to 7634 A. U. in the red. The Zeeman effects of some of these lines have also been observed with fields of 31,700 gausses. These new observations together with other available wave-length data have permitted an analysis of S II into doublets and quartets, and of S III into triplets and quintets. For the most part the spectral structures which have been established in these spectra conform to the quantum-theoretical requirements. A few exceptions are noted. The terms of S III are compared with the corresponding terms of Si I and P II by means of the irregular-doublet law; similarly those of S II are compared with Cl III. Certain numerical relations between the sepns. of the terms of the isoelectronic systems N II and O III, and P II and S III are shown to correspond to the nuclear charges of the resp. ions. C. C. KIESS

High-frequency discharges in nitrogen in the presence of mercury. R. ZOUCKERMANN. *Compt. rend.* **192**, 409–11(1931).—The spectra of N in the presence of Hg were obtained by excitation with high-frequency currents ranging in wave length from 10 m. to 570 m. The spectra were principally the bands of N_2, N_2^+ and CN, and numerous lines of at. Hg. The neg. bands of N_2, corresponding to low vibrational quantum nos., were very feeble for high-frequency currents but became very intense for currents of frequencies corresponding to wave length 570 m. The neg. bands of high quantum nos. were apparently unaffected by changes in the exciting currents. The pos. bands always appeared strongly. Likewise the Hg lines representing the P ⟶ S transitions were unaffected, whereas those representing P ⟶ D transitions were more intense for the higher-frequency currents. C. C. KIESS

The band spectra of scandium, yttrium and lanthanum monoxides. WM. F. MEGGERS AND JOHN A. WHEELER. *Bur. Standards J. Research* **6**, 239–75(1931).—The ordinary arc spectra of Sc, Y and La show, in addn. to lines characteristic of neutral and ionized atoms, complex banded structures which are ascribed to a mol. compd. of the atoms with O. These bands have the same general appearance as those due to well-known diatomic mols. and are, therefore, attributed to ScO, YO and LaO, rather than to the chemically stable oxides Sc_2O_3, Y_2O_3 and La_2O_3. The band spectra of these oxides are so complex that the fine structure of the individual bands has not been sufficiently well resolved to permit analysis of the rotational energies; consequently only a description of band heads and their classification in various systems resulting from transitions between a no. of vibration levels of initial and final electronic states can be given. The ScO spectrograms showed 139 band heads which have been divided into 5 systems, the 0, 0 transitions being represented by band heads at I, 4857.79 A. U., 4858.09 A. U.; II, 6017.07 A. U.; III, 6036.17 A. U.; IV, 6064.31 A. U.; V, 6079.30 A. U. The YO spectrum closely resembles that of ScO; 120 bands have been described for YO and divided into 5 systems with 0, 0 transitions at I, 4817.38 A. U., 4818.20 A. U.; II, 5939.08 A. U.; III, 5972.04 A. U.; IV 6096.78 A. U.; V, 6132 06 A. U. The spectrum emitted by the LaO mol. is exceedingly complex; more than 300 bands have been observed. The analysis of LaO bands agrees in the main with that given earlier by Jevons (*C. A.* **23**, 5414). W. F. MEGGERS

Theoretical value of the fundamental vibration quantum for gaseous alkali iodides. H. J. VAN LEEUWEN. *Z. Physik* **66**, 241–5(1930).—A math. calcn. from the standpoint of wave mechanics, on the assumption that the cation is small with respect to the anion, and neglecting polarization effects. The fundamental frequency ω_e 10^{-13} in sec.$^{-1}$ is for LiI 9.59, NaI 4.99, KI 3.53 and RbI 2.57, which gives $\omega/(2\pi c)$ as 509, 265, 187 and 136, resp. These agree with expt. only in the case of the first 2. G. M. E.

Rotation oscillation spectrum of acetylene. I. Band analysis. K. HEDFELD AND R. MECKE. *Z. Physik* **64**, 151–61(1930).—In order to study the configuration and form of oscillation of simple gaseous mols. the spectrum of C_2H_2 has been investigated. The spectrum was photographed in the range 9000–7000 A. U. with large dispersion (2.6 A. U./mm.). Three absorption bands were found at wave lengths 7887, 7956 and 8520 A. U., of which the 1st was by far the most intense. The absorption lines were measured to 0.01 A. U. The spectrum was analyzed. The *P* and *R* branches were very simple, no fine structure of the lines being visible within the above limit of error. There were marked intensity changes. The simple structure of the bands leads to the conclusion that the 4 atoms of the mol. are arranged in a straight line, so that the method of rotation of a diat. mol. has to be dealt with. The fact that only 1 line [*P*(0)] is missing in the spectrum is in agreement with the usually accepted electronic structure of C_2H_2 and shows the analogy of the C_2H_2 mol. HC : CH to the N_2 mol. N : N. The moment of inertia of the mol. in the fundamental state is 23.509×10^{-40}. The nuclear distance for C—H is 1.08×10^{-8} cm., in agreement with that arrived at for the CH_4

mol. by a study of the Raman spectrum; the value for the C : C distance is 1.19×10^{-8} cm. These figures are considerably less than those for the diamond lattice. B. C. A.

Rotation oscillation spectrum of acetylene. II. Intensity measurements. W. H. J. CHILDS AND R. MECKE. *Z. Physik* **64**, 162–72(1930).—Accurate intensity measurements were made with the band at 7887 A. U., this being a $^1\Sigma - {}^{'1}\Sigma$ combination. The expected intensity changes for a combination of this type were found, the i factors (*i. e.*, transition probabilities) being for the R branch, $(J)i = J + 1$, and for the P branch, $(J)i = J$. Conclusions are reached concerning the nuclear spin of elements. The intensity ratio is 3:1. The odd J values must therefore have 3 times the wt., statistically, of the even J values. The nuclear spin of the H in the C_2H_2 mol. must be 0.5, while that of the C is 0. Summing up the results previously obtained for nuclear spins, it is pointed out that elements having at. wts. divisible by 4 (equal, say, to $4n$), have no spin. This is true for He, C and O. The elements with at. wts. equal to $4n + 1$ (hydrogen) have spins equal to 0.5. Elements with at. wts. equal to $4n + 2$ (nitrogen) have the spin 1. Elements with at. wts. equal to $4n + 3$ have the spin 1.5 (lithium). The elements Na, Cl and I also have spins greater than 1. This rule should be useful in dealing with isotopic elements. B. C. A.

Rotation oscillation spectrum of acetylene. III. Characteristic frequencies of simple symmetrical molecules. R. MECKE. *Z. Physik* **64**, 173–90(1930).—The characteristic frequency of a mol. may be regarded as being made up of 2 parts —a valency oscillation and a deformation oscillation. A no. of linear mols. are considered. Mols of this type possess $n-1$ valency oscillations, equal to the no. of valency linkings, and $n-2$ deformation oscillations. The sym. mols. of CO_2, N_2O, CS_2, C_2H_2, C_2N_2 and possibly also H_2O_2 are to be regarded as linear. The triat. mols. possess 2 valency oscillations, the size of which depends mainly on the oscillating masses and one deformation oscillation, parallel to the axis of symmetry, but in the case of a linear arrangement of atoms, it becomes a double oscillation perpendicular to the axis of the mol For tetraat. mols. (C_2H_2 and C_2N_2) there are two C.H oscillations, one (HC) : (CH), and 2 deformation oscillations perpendicular to the axis of the mol. For C_2H_4 there are four C.H oscillations, one (H_2C) : (CH_2) oscillation, and 5 deformation oscillations, of which one, as a pure C:C oscillation, is independent of the mass of other atoms and is found in all derivs. contg. the C:C linking. The 5 characteristic frequencies of C_2H_2 and the 9 of C_2H_4 are calcd. B. C. A.

The ultra-violet absorption spectra of the amides of α-methylbutenoic acids. A. CASTILLE. *Bull. sci. acad. roy. Belg.* [5], **16**, 811–6(1930); *Bull. soc. chim. Belg.* 39, 417–22.—The nitriles, amides and acids described by Bruylants, Ernould and Dekoker (*C. A.* **25**, 2116) were observed in hexane and aq. solns. The *cis*-nitriles absorbed less than the *trans*-, although the effect was reversed in the acids and amides. WALLACE R. BRODE

Some peculiarities of the Raman effect. ANTONIO CARRELLI. *Rend. accad. sci. Napoli* [3], **36**, 61–8(1930).—The Raman effect and the Tyndall effect were studied for benzene and CCl_4. The Raman rotation lines are emitted with less intensity than radiation due to Tyndall scattering. The intensity of a Raman line is about one thousandth of that of the Tyndall line. For substances having absorption in the ultra-violet the intensity of the Raman light increases with diminishing wave length more rapidly than required by the λ^{-4} law, which is valid for the Tyndall effect. Theoretical treatment is included. R. H. LOMBARD

Raman effect and constitutional problems. II. Cyanogen compounds. A. DADIEU. *Ber.* **64B**, 358–61(1931); cf. *C. A.* **24**, 4706.—Previous work on the structure of allyl mustard oil and of mustard oil is supported and the constitution of isonitrile is clarified in a series of investigations of cyanogen compds. Frequency data and relative intensities are tabulated. While the structure for mustard oil, $R.N{=}C{<}_{S}^{|}$, is substantiated, it is not correct from the standpoint of the electron theory of chem. valence. The constitution of isonitrile from Raman spectra agrees well with that formulated by Langmuir (*C. A.* **13**, 3065), $R.N \equiv C$. Analogous conclusions have been reached by other investigators (cf. *C. A.* **24**, 5018, 5732) by different exptl. methods. Since in the spectrum of CO there exists a frequency in the region of the 3-fold bond it is likely that in all other compds. with bivalent C there is an analogous structure, *e. g.*, fulminic acid and its salts. The constitution of HCN can be decided on the basis of Raman spectra. Frequencies of 2094, relative intensity 12 and 2062, 1/2, indicate both HCN and HNC, the iso compd. being present in the order of magnitude of 1/2%. A. S. S.

The Raman effect in certain substances with a new apparatus. B. VENKATESACHAR AND L. SIBAIYA. *Indian J. Physics* **5**, 747–54(1930).—A new app. was designed to meet the following requirements: (1) It must permit the use of solids; (2) it must use a strong ultra-violet line for excitation; (3) it must allow the use of elevated temps. This was accomplished by enclosing the specimen in a capsule which is placed in a fused silica tube which in turn is fixed inside a larger Pyrex tube. The exciting arc is formed in the annular space between the tubes. The temp. is changed by blowing heated air through the inner tube. With increasing temp. the lines become more diffuse and the intensity of the anti-Stokes lines is enhanced as is also that of the anti-Stokes side of the wings accompanying the unmodified lines. The spectra of calcite and aragonite are given. Halite and fluorite gave neg. results. C_2H_2 gas gives lines corresponding to the infra-red absorption bands at 2.45μ and 7.5μ. The band at 13.7μ has no corresponding Raman line. J. B. AUSTIN

The Raman spectrum of nitric oxide. F. RASETTI. *Z. Physik* **66**, 646–9(1930); cf. *C. A.* **24**, 5627.—NO appears to be the only chemically stable diat. mol. with a $^2\Pi$ term as its ground state. The Raman spectrum of NO was observed and shows a pair of lines sepd. by the same $\Delta\nu$ as are the components of $^2\Pi_{1/2}$ and $^2\Pi_{3/2}$, as detd. by observations on the absorption spectrum of NO. The Raman lines corresponding to the rotation spectrum of NO were also observed, and although only partially resolved, are in qual. agreement with those required by theory. C. C. KIESS

Raman effect in solutions of sodium nitrate of varying concentrations. V. STERLING AND E. R. LAIRD. *Phys. Rev.* **36**, 148–9(1930).—The Raman spectrum of 5, 10, 30% satd. solns. of $NaNO_3$ shows a line with a frequency difference of 1049 ± 6 cm.$^{-1}$. It is attributed to the NO_3 ion. BERNARD LEWIS

Studies in Raman effect. X. The Raman spectra of organic substances. A. DADIEU AND K. W. F. KOHLRAUSCH. *Sitzb. Akad. Wiss. Wien*, Abt. IIa, **139**, 459–72(1930); *Monatsh.* **57**, 225–40(1931); cf. *C. A.* **25**, 875.—Measurements of propyl-, diethyl-, diphenyl-, trimethyl- and triethylamines, aniline, formamide, dicyanodiamide, methylnitroamine, chloral, ethyl chloroformate, chloracetyl chloride, dimethyl and diphenyl ethers. The spectra of 16 amines are compared. L. ONSAGER

Raman effect in methyl halides. GAJENDRA NATH BALL. *Z. Physik* **66**, 257–60(1930).—The 2 bands at 16.8 and 19.6μ for CH_3Br and CH_3I which were beyond the range of Bennett and Meyer (cf. *C. A.* **23**, 2657) but which were predicted by them, have been found. Complete measurements to 0.001 mm. have been made of Raman spectra for all of the methyl halides, and are compared tabularly with B. and M. and Kohlrausch. GREGG M. EVANS

Raman effect in trimethylethylene. D. FRANKLIN AND E. R. LAIRD. *Phys. Rev.* 36, 147(1930).—Raman lines in trimethylethylene were found which correspond to infra-red lines at 3.44 ± 0.05μ and 8.4 ± 0.2μ. An anti-Stokes line was found at 8.4μ. BERNARD LEWIS

Raman spectra of organic sulfides. V. N. THATTE AND A. S. GANESAN. *Nature* 127, 306(1931).—The Raman spectra detd. are as follows, expressed in cm.$^{-1}$: Et_2S 652, 1061, 1282, 1439, 2923; allyl sulfide, 410, 588, 741, 917, 1011, 1101, 1210, 1291, 1312, 1420, 1534, 1636, 3007, 3088. The frequency 652 seems characteristic of satd. sulfides; the frequency 751 a characteristic of unsatd. sulfides A. F.

Color and constitution from the standpoint of recent electronic theory. IV. Various types of anomalous nitration; chelation; complex salt formation; unusual stability of substituted aminophenols; direct diacetylation of amines; inhibited hydrolysis of sulfonic acids; reaction of caustic potash with benzaldehyde. H. H. HODGSON. *J. Soc. Dyers Colourists* **46**, 183–8(1930); cf. *C. A.* **24**, 4223.—The reaction of HNO_2 with dimethyl-*p*-toluidine to give monomethyl-*p*-toluidine-*N*-nitrosoamine and 3-nitrodimethyl-*p*-toluidine is described and explained. It was observed in a series of isomeric and homologous compds. that the picrates in which the greatest salt formation occurred had the higher m. ps., while those where the union was of a more chelate type had lower m. ps. The anomalous behavior of the picrate of dimethyl-*p*-toluidine is explained. The direction of nitration of anilides and phenols, *o* or *p*, is detd. by the strength of the cation of the nitrating agent used. Strong cationoid reagents cause para nitration and weak ones ortho. The stability of the 3-halo-2(4, and 6)-aminophenols is considered to be due to the prevention of inner-salt formation by the constraint imposed on the electrons of the N by the halogens. The fact that acetylation of 2,6-dichloro-4-nitroaniline produces always the di- instead of the mono-acetylated product is explained by assuming a mol. rearrangement after the introduction of the first acetyl group which greatly facilitates further acetylation. The effect of other ring substituents on the case of hydrolysis of sulfonic acids is explained. The reaction of caustic potash with

BzH is explained by assuming the formation of an isomeride of benzoin which subsequently decomposes to form benzyl alc. and BzOH. T. G. HAWLEY

Chemical decomposition by radiation. G. HARKER. *J. Cancer Research Comm. Univ. Sidney* **2**, 111–8, 160–81(1930).—A review with bibliography. Radiation as applied in therapeutics is also discussed. G. SCHWOCH

Mechanism of the chemical action of x-rays in aqueous solutions. O. RISSE. *Strahlentherap.* **34**, 578–81(1929); cf. *C. A.* **24**, 5602.—Ultra-violet irradiation of water whether in presence or absence of O, did not lead to the formation of H_2O_2 unless Zn oxide was present; x- or β-irradiation of pure water leads, however, to its formation. H_2O_2 is decomposed by all 3 radiations. The reaction depends on the dissolved O; hence the presence of dissolved O in irradiated solns. may cause changes dependent on the primary formation of H_2O_2. The conversion of ferrous into ferric salts is an example. The mechanism of the formation of H_2O_2 is discussed. B. C. A.

A new method of preparation of phosphorescent zinc sulfide. JOSEF EINIG. *Chem.-Ztg.* **55**, 31(1931).—After illumination, ZnS becomes phosphorescent if it be otherwise as nearly pure as possible, but mixed with a small quantity of a heavy metal, particularly Cu, and heated to above 900° to convert the ZnS to cryst. form. Very nearly pure ZnS contg. less than 1/100,000 per 1000 parts of heavy metals does not phosphoresce. The amt. of Cu required to make ZnS phosphoresce is 0.00001–0.001 part; outside these limits there is no phosphorescence. The new process consists in purification of $ZnSO_4$ soln. by causing a slight pptn. by addn. of H_2S or Na_2S, then heating to ppt. all metal sulfides less sol. than ZnS. Sulfides more sol. than ZnS remain in soln. and can only be removed later, since they form during the reaction. ZnS so formed does not phosphoresce, but can be made to do so by addn. of the required amt. of Cu The product is superior in luminosity to the com. product. E. M. SYMMES

Extinction of fluorescence of solutions of dyes by electrolytes. A. V. BANOV *Z. Physik* **64**, 121–34(1930); cf. *C. A.* **24**, 2052.—The application of the theory of Vavilov concerning collisions of the 2nd kind to the extinction of fluorescence in solns of dyes by adding electrolytes does not agree fully with exptl. results. This leads to the search for some other cause of extinction which is to be found in the "salting-out" effect of the electrolyte on the dye. Exptl. work supports this view. Calcns. of the sum of the radii of the mol. of the dye and of the ion of the electrolyte give results in agreement with those arrived at by other methods. The extinction curves reveal a connection between the concn. of the electrolyte, c, and the intensity ratio after and before adding the electrolyte, which can be expressed in the form $L/L_o = e^{-k\sqrt{c}}$. B. C. A.

Photoreaction of hydrogen and iodine monochloride. S. E. ASHLEY AND WILLIAM WEST. *Nature* **127**, 308(1931).—Impurities reduce the rate to a small but measurable value, confirming Mellor and Iredale (cf. *C. A.* **25**, 1736) but not agreeing with Rollefson and Lindquist (cf. *C. A.* **24**, 4224; **25**, 1736). The photoreaction between CH_4 and ICl is very rapid. ARTHUR FLEISCHER

Photochemical kinetics of chlorine detonating gas. Oxygen-free gases. MAX BODENSTEIN AND WALTER UNGER. *Z. physik. Chem.*, Abt. B, **11**, 253–78(1930); cf. *C. A.* **8**, 452; **20**, 3646; **21**, 3527.—H was prepd. O-free by passage over heated Pd asbestos and diffusion through Pd. Cl was liquefied and swept out with pure H. Fractionation under low pressure was also used. The reaction between H and Cl was followed by the methods of Dux and Thon in a quartz vessel, illuminated with light of 4360 A. U. Without O the reaction followed the mass law, $d[HCl]/dt = k[H_2].[Cl_2]$ and considering the intensity, of the absorbed light $d[HCl]/dt = k.I.[H_2]$. The breaking of reaction chains by reactions on the vessel walls was found proportional to [Cl]. To account for this the hypothesis of diffusion of Cl atoms to the walls and recombination there appeared untenable. This effect was due to formation of a volatile compd. of Cl and Si from the container walls. The influence of temp. was studied from 30° to 167° by a streaming method. The effect of small amts. of O was further investigated. L. P. HALL

Cystine and its absorption spectra. D. BARNÉS. *Anales soc. espaü. fís. quím.* **28**, 1386–1406(1930).—A spectrographic study of the absorption spectra of cystine and alanine in HCl soln. was made by a sector photometer with a small quartz spectrograph to analyze the light absorbed by the amino acid in a Baly tube. The light source was a discharge through pure H_2 at a pressure to give a continuous spectrum. The results are shown graphically by plotting the mol. absorption coeff. against wave length. They agree with Ward (*C. A.* **18**, 1117) within exptl. error. Curves obtained with cystine and alanine are similar, and show no selective absorption. The alanine absorption begins further in the ultra-violet, and the curve is incomplete because of limited instrument sensitivity. Intensity of absorption increases with short wave lengths.

From the detn. of wave length at which absorption begins, energy of dissocn. or $h\nu$ = 4.9×10^{-12} ergs per mol., and the heat of dissocn. = 70,800 cal. per g.-mol., and for alanine $h\nu = 5.75 \times 10^{-12}$ and H = 83,000, resp. The structure of cystine is aliphatic. Cystine is more easily dissocd. than alanine. E. M. SYMMES

Absorption spectra of bibenzyl and its derivatives. MME. RAMART-LUCAS AND J. HOCH. *Compt. rend.* **192**, 53–5(1931).—Bibenzyl and its derivs., prepd. by the action of Mg or Na on BzCl or similar compds. gave compds. with 2 absorption bands, (*a*) between 3300 and 2700 A. U. and (*b*) between 2700 and 2300 A. U. Similar compds. prepd. by the action of $PhCH_2CH_2Br$ on benzene in the presence of $AlCl_3$ gave compds. with a band at 2700–2300 A. U. only. Further investigation showed band *a* to be due to stilbene. WALLACE R. BRODE

The action of radiation on colloids. III. Action of ultra-violet light on emulsions. P. C. SINHA AND B. G. GANGULI. *Kolloid-Z.* **54**, 147–50(1931); cf. *C. A.* **24**, 540, 5632.—Emulsions of C_6H_6, benzine and CS_2 in water with Na oleate as the emulsifier sepd. into 2 layers on illumination. The p_H of the illuminated emulsion increased, indicating that the breaking is due to a partial destruction of the emulsifying agent. A. F.

Colloidal nature of the coloring substance in colored rock salt. M. SAVOSTYANOVA. *J. Physik* **64**, 262–78(1930).—Mie's theory was applied to the system Na–NaCl, and the absorption and diffusion spectra for different particle sizes were calcd. and compared with the exptl. curves obtained for colored rock salt. The absorption spectra of the following kinds of colored salts were detd. by the spectrophotometer method: (*a*) natural blue salt, (*b*) additive (in liquid Na) colored salt and (*c*) salt obtained from yellow salt by the action of heat and pressure under the influence of light. The exptl. data agree with the assumption that the colors are due to particles of colloidal Na. Besides the absorption maxima due to the presence of colloidal Na, a further max. was found for yellow salt in the infra-red, the explanation of which is not clear. B. C. A.

The influence of light on the flocculation of colloidal solutions in fluorescent media. Role of antioxygens. AUGUSTIN BOUTARIC AND JEAN BOUCHARD. *Compt. rend.* **192**, 357–8(1931); cf. *C. A.* 1738.—In continuation of the work previously described, the parallelism between the effect of some electrolytes in depressing the fluorescence of fluorescein solns. and their effect on the flocculation of As_2S_3 sols by light in presence of fluorescein is studied. The difference Δt between the time required for flocculation in the dark and in daylight or ultra-violet is approx. proportional to the logarithm of the fluorescing power of the mixt. of fluorescein and the electrolyte. H_2SO_4 gives the greatest effect, LiCl none. Tannin, hydroquinone, phenol and cresol in presence of LiCl also reduce both fluorescing power and Δt. Fluorescing power was detd. by the fluorometer of Perrin. The possible biol. significance is discussed. K. V. T.

Concentrating radioactive substances. KURT WEIL and KURT PETERS. Ger. 518,205, Dec. 21, 1929. The concn. of active substance in radioactive carbonate mixts. is raised by fractional thermal decompn. followed by washing with water. Thus, a mixt. of $RaCO_3$ and $BaCO_3$ may be heated to 400° *in vacuo*, cooled and washed with hot water, a residue richer in Ra than the initial mixt. being obtained.

Activating metals or alloys. OSKAR RIED. Austrian 121,243, Sept. 15, 1930. Metals or alloys are subjected to radiations of suitable wave length, *e. g.*, to ultra-violet radiations, whereby they are physically and biologically activated. Numerous applications of the invention are mentioned. Thus, the growth of yeast may be influenced by effecting the cultivation in irradiated metal vessels, or the stability of milk under trans-

port may be improved by using irradiated metal cans, or butter or cheese may be packed in irradiated metal foil.

Theoretical consideration of the oxidation of pig iron during its transformation into steel. MIKIO MUKOHYAMA. *Tetsu-to-Hagané* (*J. Iron and Steel Inst. Japan*) **16**, 1041–57(1930).—From the mass-action law, M. deduced the formula for the equil. const., $K' = dx/dt \cdot (1/(a + K'-x)(b-x))$, where x is the density of C at time t, a and b are the initial contents of FeO and C, resp., and M is the diffusivity of FeO when no reaction occurs. To eliminate M, he obtained an approx. value of $K' = 1/t \cdot \log_e b/(b-x)$. Expts. were undertaken to obtain values for b. After heating the mixt. of pig and hematite in a resistance furnace and an induction furnace, the products were examd. by chem. analysis and microscopic observation. Results showed that $K' = 0.060$ at 1450° and 0.066 for 1500° in the induction furnace and 0.069 and 0.067, resp., for the resistance furnace. M. KURODA

High-frequency induction furnaces for making tool steel. J. A. SUCCOP. *Metal Progress* **18**, No. 6, 40–4(1930).—A review. W. A. MUDGE

A new cyanide furnace. R. F. JAMES AND GLENN COLEY. *J. Franklin Inst.* **211**, 327–34(1931).—A new elec. resistance furnace has been constructed on the hypothesis that the maintenance of an oxidizing atm. in the heating element chamber at all times is essential to the preservation of the elements. A drawing is shown. The test pot had an input of 43 kw. After a service of 1800 work hrs., a check of the element showed a power input of 42.5 kw., which is a considerable improvement over the power-consumption curves from previous designs. No scale was found on the heating elements, but the pot showed traces of leakage and a heavy deposit of what appeared to be cyanates on the floor of the element chamber. Elec. tests and phys. examn. showed no deterioration of the elements. This furnace consistently produced over 4 lb. of work per kw. hr. without any covering of the pot. A full charge of work was delivered in 18 to 20 min., which is well within the production speed desired. Appreciable quantities were lacking of the black sludge usually formed on the surface of molten NaCN. H. C. P.

Bright anneal in artificial atmospheres. J. C. WOODSON. *Elec. J.* **28**, 246–7 (1931).—Electrically heated furnaces are very successfully used for bright anneals. Partially cracked and purified coke-oven gas and treated blast-furnace gas are not entirely satisfactory for the bright anneal of certain metals; H, dissocd. NH_3, natural or city gas (with or without water vapor), MeOH and butane are similarly used. Blast-furnace and coke-oven gas are used on low-C, cold-rolled steel; cracked butane is used on high-C steel or roller-bearing stock. The artificial furnace atm. will probably soon be adopted in fabricating and mfg. processes. W. H. BOYNTON

The electrolytic industry of Germany. V. ENGELHARDT, *et al.* *Trans. 2nd World Power Conference* (Berlin) I, 317–48(1930). E. H.

Operating data on electrolytic metal production and refining. C. L. MANTELL *Eng. Mining J.* **131**, 256–9(1931).—Operating data from the electrolytic plants of the U. S. and Canada show: the compn. of electrolytes, equipment, methods of applying the current and efficiency obtained from the power, raw materials used, and by-products produced. The tables cover the electrolytic refining of Cu, the electrolysis of Cu-bearing solns. obtained by leaching processes, and the production of Zn, Cd, Pb, Ni, Sn, Ag and Au. The high power cost of processes using insol. anodes is indicated in the tables. The diaphragm used in Ni production causes an increase in cell voltage with attendant high power costs. W. H. BOYNTON

Factors affecting the smoothness and mechanical properties of electrodeposited copper. A. W. HOTHERSALL. *J. Electroplaters' and Depositors' Tech. Soc.* **6**, 95–122, *Metal Ind.* (London) **38**, 343–6(1931).—Growth formation, unequal current distribution, maintenance of an adequate supply of Cu ions at the cathode, factors which tend to reduce the rate of Cu deposition in practice and the detn. of the influence

of the more favorable depositing conditions on the mech. properties of the deposits are discussed. From solns. contg. 200 g. $CuSO_4.5H_2O$ and 50 g. H_2SO_4 per l. (Soln. *A*) (temp. = 26°), variations in c. d. from 15 to 200 amp./sq. ft., with or without air agitation, caused little change in the Brinell hardness (from 42 to 52) of the deposited Cu. Increasing c. d. and increasing acid concn. caused slightly harder deposits to be given. A hard deposit (Brinell no. 81) was obtained at 15 amp./sq. ft. from a soln. contg. 200 g. $CuSO_4.5H_2O$ and 20 g. $(NH_4)_2SO_4$ per l. and no free acid. A very hard, smooth and exceedingly brittle deposit of polished appearance was obtained at 16° and 15 amp./sq. ft. from a neutral soln. contg. $CuSO_4$ and NH_4NO_3. The unequal current distribution (particularly marked in Cu deposition because of the steepness of the cathode potential-c. d. curve), together with the formation of nodular growths, due to (*a*) irregular crystal growth of the deposit and (*b*) adherence of electrically conducting particles (formed in the soln.) to the cathode surface, and the effect of agitation on the above factors, is discussed in detail. Precautions (*e. g.*, warm solns., filtration, adjustment of agitation to c. d. being used and correct pickling of cathode basis metal) which should be taken in solns. contg. no addn. agents in order to secure smooth Cu deposits are reviewed. The effects of various addn. agents in Cu deposition, the control of such substances, the mechanism of their action and the mech. properties of Cu deposited from solns. contg. addn. agents are discussed. Addns. of $Al_2(SO_4)_3$ up to 32 g./l. to Soln. *A* (above) had no effect on the mech. properties of deposits obtained on a rotating cathode (peripheral speed 450 ft./min.) at 50 amp./sq. ft., nor on the cathode potential. The ductility of the Cu deposited from Soln. *A* upon the rotating cathode was considerably increased by the addn. of 0.06 g./l. Cl (as NaCl), the % elongation increasing from 33 to 48, and at the same time the tendency for finely divided Cu to form in soln. was retarded. Although beneficial in agitated baths, in still baths the Cl induced the growth of thin needle-like single crystals. The addn. of the requisite amt. of Ag_2SO_4 soln. to remove the Cl from such baths caused them to yield satisfactory deposits subsequently. Addns. of gelatin and peptone to Soln. *A* caused the deposits to have smaller crystals and to be smoother, harder and more ductile. The Brinell hardness of the deposits from still baths increased from 42 to 83–93 by 2 p. p. m. of these substances, and 0.01 g./l. gelatin raised the hardness to 128. Dextrin, up to 10 g./l., had little influence on the hardness and crystal size of the Cu from freshly prepd. solns., but when "aged," such solns. gave harder and more brittle deposits. Cu from freshly prepd. solns. (*A*) contg. up to 10 g./l. phenol (as phenolsulfonic acid) was similar in properties to, but much smoother than, that from solns. contg. no addn. agents. On continued electrolysis the effect of the phenol and also of the gelatin and of peptone disappeared. The hard deposits given in "aged" solns. contg. phenol were more ductile than those formed without addn. agents. Dextrin is concluded to be the least suitable addn. agent; the pronounced effects of gelatin and peptone make it necessary for very small quantities to be used—with the consequent difficulty of estn. and control of the amt. present—whereas phenol can be used up to 10 g./l. and can be detd. analytically (Hull and Blum, *C. A.* **25**, 460). Tables are given showing the hardness of the deposits from solns. free from addn. agents, and also the effect of addn. agents on the hardness and tensile properties of the deposits from still and from air-agitated solns. Cathode potential-c. d. curves for solns. with and without addn. agents, both for freshly prepd. and for "aged" solns., are given, as well as photographs of some deposits (including nodules and single crystals) and their micro-structures. A bibliography is appended. EDWARD B. SANIGAR

The reduction of arsenic acid and arsenates to arsine at the mercury cathode. I. WM. V. LLOYD. *Trans. Faraday Soc.* **27**, 89–94(1931).—A rotary commutator was used to connect the cathode to the source of current and a potentiometer alternately 3000 times a min. The overpotential decreased by 0.5 v. to that of As, although analysis of the Hg cathode showed no As present. The decrease in overpotential was less when an uninterrupted current was used, and varied directly with increasing concn. of H_3AsO_4. The quantity of AsH_3 produced increased with increasing H_3AsO_4 concn. The efficiency of the reduction process, based upon the H converted into AsH_3 at the cathode, varied from 1.71 to 14.1%. Cf. *C. A.* **24**, 1582. CURTIS L. WILSON

Temperature measurements on working electrodes. IV. B. BRUŽS. *Z. physik. Chem.*, Abt. A, **153**, 309–20(1931); cf. *C. A.* **24**, 3179.—The electrolytic Peltier effect which occurs in working electrodes was evaluated with the help of a dynamic calorimetric method, a detailed discussion of the theory of the method being included. The Peltier effect is measured for Hg | Hg_2^{++} in perchlorate and nitrate solns. at different concns., and the results are applied to the calcn. of the partial entropy of Hg_2^{++} ion for the same concns. For solns. of unit activity this is 29 ± 1 cal./degree. H. STOERTZ

The composition of manganese amalgam and manganese-silver alloys in relation to

the electrode potential of manganese. HARVEY D. ROYCE AND LOUIS KAHLENBERG. *Trans. Electrochem. Soc.* 59 (preprint) 23 pp.(1931).—Four Mn-Ag alloys were prepd. from highly purified materials. Electrode potentials and replacing power of these alloys have been measured. The replacing power and potential of alloy D (31 at. % Mn) were correlated with alloy structure by means of photomicrographs and thermal diagrams. None of the Mn-Ag alloys yields electrode potential approaching that of Mn amalgam. Mn amalgam consists of solid Mn_2Hg_5 in equil. with a very dil. soln. of Mn in Hg (0.0032% Mn). The behavior of Mn amalgam in contact with Mn salt solns. has been interpreted on the basis of these figures. A new compd. of Mn and Hg, isolated from the dil. amalgam by the application of pressures exceeding 150,000 lb. per sq. in. (10,500 kg./sq. cm.) and having the formula MnHg, is described. MnHg constitutes the stable solid phase in the system Mn–Hg at temps. between 86° and 100°. Pressure-concn. curves are presented to justify the assumption that the solid phase obtained by pressure is MnHg contaminated with a small percentage of the liquid amalgam. C. G. F.

Bright silver plating from the cyanide bath. A preliminary note. L. C. PAN. *Trans. Electrochem. Soc.* 59 (preprint) 5 pp.(1931).—A no. of chemicals were investigated with regard to their brightening effect upon electrodeposits of Ag from the cyanide bath. NH_4OH was found to have a decided whitening effect upon silver deposits, and was especially effective in an electrolyte containing large amts. of impurities. Na thiosulfate at a conc. of about 1 g./l. was found to be a good brightener for the Ag bath, and more effective than CS_2. The combination of NH_4OH and Na thiosulfate in a Ag bath produces a bright deposit similar to bright Cr, even in the presence of impurities which ordinarily cause dark yellow deposits. With the above brighteners, bright deposits are possible at moderately high current densities. C. G. F.

The change in reflecting power caused by tarnishing electrodeposited silver-cadmium alloys. LAWRENCE E. STOUT AND WILLIAM G. THUMMEL. *Trans. Electrochem. Soc.* 59 (preprint) 13 pp.(1931).—AgCd alloys can be deposited from a commercial Cd-plating bath to which AgCN has been added. The compn. of the alloy depends on the Ag concn. in the bath (if the Cd content remains const.) and on the cathode c. d. The co-deposition of Ag lowers the reflecting power of electrodeposited Cd. The tarnishing of the alloys depends both on the compn. and on the rate of deposition and is materially less than that of pure Ag. A Ag-Cd alloy contg. about 24% of Ag recommends itself as the best general-purpose reflector. Its reflecting power is equal to that of pure Cd, and it is considerably harder and more resistant to abrasion than pure electrodeposited Cd. C. G. F.

Progress of the hot nickel solution. OLIVER P. WATTS. *Trans. Electrochem. Soc.* 59 (preprint) 5 pp.(1931).—A report is made of the vol. and operating conditions of many of the hot Ni-plating solns. now in use in the U. S. and Canada. Since there was a period of 5 years between the announcement of the advantages of heating the Ni-plating soln. and its commercial adoption, the reported growth to 158,000 gallons has occurred in 10 years. Opinions of platers on the respective merits of the hot and cold Ni solns. are included. C. G. F.

Control of acidity in low-p_H nickel-plating baths. L. C. PAN. *Trans. Electrochem. Soc.* 59 (preprint) 8 pp.(1931).—For the control of acidity in Ni-plating baths of low p_H, the titration method, including a "control chart" for direct readings, was found to be most practical in a commercial plant. It is based upon the assumption that for a given bath, whose compn. is kept approx. const., the p_H value will be the same as long as the acidity is maintained at the same point. The "control chart" also provides a direct method of regulating and correcting the acidity or p_H, eliminating all labor of computation and all guesswork. C. G. F.

Chromium deposits directly on aluminum. HAROLD K. WORK AND CHARLES J. SLUNDER. *Trans. Electrochem. Soc.* 59 (preprint) 7 pp.(1931).—Thin layers of Cr which have fairly good resistance to salt spray and atm. corrosion may be electrodeposited directly on Al. Such deposits have a gray color on leaving the plating bath and must be buffed if a higher luster is required. These deposits protect Al to a marked degree from alkaline corrosion. Heavy deposits for abrasion resistance have also been applied to certain Al alloys. C. G. F.

The electrodeposition of chromium and the influence of the cathode metal. J. W. CUTHBERTSON. *Trans. Electrochem. Soc.* 59 (preprint) 24 pp.(1931); cf. *C. A.* 25, 35.—In Cr plating the best results and greatest flexibility and reliability in operation are obtained from a soln. of CrO_3 and H_2SO_4. The molarity of the CrO_3 should not be greater than 3.25, and the ratio of this to SO_4 normality should be about 58 to 60. The tank should be lined with hard Pb, the lining *not* being anodic to the soln. except as a

temporary measure. Pb is the only material that can be considered for anodes. The temp. should be reasonably high, but not above 45°, as then the Cr^{III} equil. conc. reaches too high a figure. Care should be paid to the ratio between anode and cathode surfaces. The anode area should be 1.5 to 3 times that of the cathode, and anodes should be disposed with respect to the cathode size and shape. Even under the best of conditions, the cathode current efficiency is not above 16%. The nature of the cathode is of the greatest moment. It should be of a metal of high H overvoltage corresponding to that of Cr. Ni is the material mostly used now, but it is far from ideal. For many purposes Cu is a far better undercoating. It is impossible to increase materially the throwing power of CrO_3 solns. The best way to improve upon existing conditions is to increase the plating range in which bright plate is obtainable. Except in the case of Cu little success has been obtained from Cr deposits direct on the base metal. This may be due to the inherent porosity of these deposits. Direct deposits can be improved by heat treatment, but this does not lend itself readily to commercial practice. C. G. F.

Electrodeposition of chromium-iron alloy. G. Fuseya and K. Sasaki. *Trans. Electrochem. Soc.* 59 (preprint) 24 pp.(1931).—See *C. A.* 25, 1164(1931). C. G. F.

Chromium-plated molds. H. E. Stockfisch. *Am. Machinist* 73, 553–5(1930).—The advantages are given of Cr-plated surfaces in the molding of glass, brick and micarta to reduce wear and improve finish, and the compn. and treatment of molds are discussed. E. I. S.

The electrodeposition of tungsten from aqueous solutions. Colin G. Fink and Frank L. Jones. *Trans. Electrochem. Soc.* 59 (preprint) 23 pp.(1931).—The W deposited from aq. solns. is smooth, hard and coherent and has a high luster. Like Cr, it needs no polishing if the plated article was previously polished. W has remarkable acid-resisting properties, which make it desirable as a protective coating for other metals. Several types of solns. have been investigated in regard to their usefulness as W plating baths. Solns. of W salts in org. solvents are unsuitable. Aq. solns. of an acid nature do not give satisfactory metal deposits. Alk. solns. contg. alkali tungstates are preferably used as plating baths. The temp., cathode c. d. and H-ion concn. of the soln. must be controlled. Alloys of W and Fe, and of W and Ni, were electrodeposited from similar solns. contg. very small concns. of the ions of these second metals. The usefulness of highly alk. solns. as plating baths for the electrodeposition of other metals is pointed out. C. G. F.

The production of hydrogen at certain metal surfaces in relation to overvoltage. G. Raymond Hood and Francis C. Krauskopf. *J. Phys. Chem.* 35, 786–95(1931).—The efficiency of electrolytic reduction of $KClO_3$ (in 0.493 *N* soln.) was detd. concurrently with the cathode potential *V* (measured against a satd. calomel electrode with a KCl bridge), various metal cathodes and several c. ds. being used. The data for different cathode materials conform to the same relation between *V* and reduction efficiency; the efficiency decreases with increasing *V*, and is negligible for $V > 1.5$ v. Measurements of the decompn. potentials of H_2SO_4 (0.1 *N*), KCl (0.493 *N*) and $KClO_3$ (0.493 *N*) with Pt anodes and various cathodes are given and compared with the reduction expts. L. O.

Electrolytic production of hydroxides and hydrogen. R. Saxon. *Chem. News* 142, 85, 113–4, 149–50(1931).—These articles are statements of the phenomena occurring when pure H_2O (contg. no acid or salt for conduction) is electrolyzed, 240 v. being used, with Pt or C cathodes and anodes of various metals. The gas liberated at the cathode was collected over H_2O and found to be H only. The solns. took on various colors depending on the metal used as anode, and metal hydroxides were formed in the solns. Expts. with the following metals as anodes are reported: *Fe.*—The soln. turned umber, then green; green $Fe(OH)_2$ formed in the soln., while a scum of $Fe(OH)_3$ floated on the soln., even that in contact with the cathodic H. The soln. was acid to methyl orange but gave no test for Fe unless acid was added. It is concluded that the natural tendency is for $Fe(OH)_3$ to be formed, but that the nascent (not the molecular) H reduces this to $Fe(OH)_2$. *Cu.*—The soln. turned green and, later, green-blue to purple. The nascent H reduced the $Cu(OH)_2$ first formed to CuOH and then to Cu which floated on the surface of the soln. The $Cu(OH)_2$ first formed was found to be electropositive. *Co.*—The soln. became pale bluish: a green-blue scum, thought to be $Co(OH)_3$, collected on the H_2O in the tube over the cathode. Red-brown flakes of $Co(OH)_3$ appeared in the soln. followed by brown and black masses of Co_2O_3 and CoO. *Ni.* An apple-green film of $Ni(OH)_3$ was observed followed by a green scum of $Ni(OH)_3$ and, later, floating specks of Ni_2O_3, followed quickly by green NiO. From the expts. it is concluded that the reductions are brought about only by nascent H (not by molecular H_2), and that Ni is preferentially divalent, Fe preferentially tri-valent, while Co is bi- and ter-valent without preference. Edward B. Sanigar

The use of antimonial lead for accumulator grids: a cause of self-discharge of the negative plates. J. T. CRENNELL AND A. G. MILLIGAN. *Trans. Faraday Soc.* **27**, 103–12 (1931).—It was observed that the neg. plates of Pb accumulators at high temps. and high acid concns. lost capacity as the cells became older. The use of exptl. cells with pure Pb grids and with grids of antimonial Pb indicated that the "aging" of the neg. plate was due to the soln. of Sb from the alloy of the pos. plate and its deposition on the neg. plate. The low H-overvoltage at an Sb surface reduced the current efficiency of the plate by allowing evolution of H. Sb added to the electrolyte produced the same effects. No quant. relation between the total Sb added and the rate of sulfation of the neg. plate could be established. It is concluded that antimonial Pb should not be used for the pos. grids of Pb accumulators. CURTIS L. WILSON

Diatomite as a filler in battery boxes. PAUL HATMAKER. Bur. Mines, *Rept. of Investigations* 3078, 2 pp.(1931).—Diatomite for battery fillers must have < 8–10% acid-sol. material and < 0.75% Fe and be low in clay and org. substances. Mn and MgO are objectionable. Present consumption for this use is 10,000–15,000 tons annually. ALDEN H. EMERY

Electricity in modern dairy plants. A. J. DREUX AND H. C. BRUNNER. *Elec. Eng.* **50**, 285–7(1931).—The elec. current passes through the milk in the Electropure method of pasteurizing. The application at the Rieck-McJunkin Dairy in Pittsburgh, Pa., is described, also other uses of electricity in such plants. W. H. BOYNTON

Electrochemistry applied to glass. ALEXANDER SILVERMAN. *Trans. Electrochem Soc.* **59** (preprint) 9 pp.(1931).—Accessory applications of electrochemistry to glass manuf. are discussed, *e. g.*, cond. as a control of viscosity; elec. pptn. in purifying producer gas; Cr plating of molds; and electroplating of the finished product with various metallic coatings. A review is given of studies that have been conducted on the electrochem. properties of glass, such as conductance through the glass in d. c. electrolysis. C. G. F.

Influence of traces of hydrogen on sparking potential of helium. A. GÜNTHERSCHULZE AND F. KELLER. *Z. Physik* **66**, 219–23(1930).—The disappearance of the last traces of H in glow lamp rectifiers caused an increase in the flash-over voltage from 182 to 330 v. This is explained by reference to the four-fold longer mean free path of the H ion over other positive ions. GREGG M. EVANS

Current collection in hydrogen atmosphere. R. M. BAKER. *Elec. Eng.* **50**, 266–7 (1931).—Test runs of commutators and slip rings operating in H_2 gas reveal interesting characteristics and lead to the following conclusions: A commutator machine designed and adjusted for good commutation in air will operate satisfactorily and give good brush life in H_2. If a commutator machine must spark in H_2, the brush life may be increased many times by keeping the relative humidity below 10%. The contact resistance of C brushes on a commutator may be lowered by the introduction of H_2. C or graphite brushes cannot be operated satisfactorily on plain tool-steel slip-rings running in H_2. The contact drop between a C or graphite brush and a brass slip-ring may be 10 times as high when the ring is running in air as when in H_2. W. H. B.

The development of an electron-emitting alloy. O. S. DUFFENDACK, R. A. WOLFE AND D. W. RANDOLPH. *Trans. Electrochem. Soc.* **59** (preprint) 17 pp.(1931).—It was discovered that irregularities in the sparking voltage of spark gaps were due to nonuniformities in the compn. of the electrode materials. Small inclusions of Mg in the Ni alloy ordinarily employed for spark plug electrodes were found to be distributed at random through the wire and to affect the sparking voltages. A thorough investigation established a complete coördination between the sparking voltage of a gap and the work function of electron extn. from the cathode surface. The sparking voltage of a standardized gap increases when the thermionic electron emission of the electrode wire, measured under standardized conditions, decreases. After many expts. a Ni alloy contg. Ba has been developed which is homogeneous in compn. and readily reproducible. Spark gaps having electrodes made of this alloy have very const. sparking voltages. The alloy has marked electron-emitting properties that make it valuable for use in various elec. devices. Its uses in several ways are being developed. C. G. F.

The decomposition of iron oxide in vacuum tubes. E. R. WAGNER. *Trans. Electrochem. Soc.* **59** (preprint) 3 pp.(1931).—An oxidized Fe anode in a vacuum tube, type "245," liberated large quantities of gas during the operation of the tube. If the potential gradient is increased to 300 v., the emission of gas is almost instantaneous. The phenomenon does not appear to be a purely electrolytic one, but rather due to electron bombardment. C. G. F.

New photoelectric cells with potassium. ANON. *Ann. chim. anal. chim. appl.* 13,

72–5(1931).—In the new cells, the cathode is a deposit of K on the interior wall of the bulb, and the anode consists of straight or curved metallic filaments. Each electrode is connected with an external circuit of high resistance (100,000 ohms to 100 megohms) and to a storage cell which creates between the electrodes an elec. field to accelerate the electrons emitted from the cathode. In the dark, the cell presents infinite resistance and permits the passage of no current in the external circuit. The very feeble current produced by the action of light is amplified by a lamp with 3 electrodes, and its variations can be measured directly with a milli-ammeter. The photoelec. cell and the triode amplifier are mounted in a metallic case, and the cells are preferably filled with a gas like A. W. T. H.

Production of color from tungsten lamps. M. LUCKIESH. *Elec. World* **97**, 645 (1931).—In order to obtain colored light from a lamp it is necessary to filter out the undesired colors, but it is impossible to obtain light of a pure, spectral color by means of filters. W. H. BOYNTON

The condensation of hydrocarbons by electrical discharge. A study of the M/N-ratio for methane, ethylene and acetylene. S. C. LIND AND GEORGE R. SCHULTZE. *Trans. Electrochem. Soc.* **59** (preprint) 16 pp.(1931); cf. *C. A.* **25**, 1440.—An accurate method is given for taking into account all temp. effects which have involved some uncertainty in judging the pressure changes during the expts. in the course of the earlier investigations. The properties and the applicability of the system employed for the measurements, namely, the ozonizer type of discharge, are discussed. For the acetylene condensation, a neg. catalytic wall effect of the solid reaction product on the condensation velocity has been discovered. The condensation of CH_4, C_2H_4 and C_2H_2 was studied in an elec. discharge with respect to the yield of ionization as represented in the M/N-ratio of the condensation, where M equals the no. of reacting mols. and N, the no. of pairs of charges. The same proportionality was found for the M/N-ratios of CH_4 and C_2H_2 (2:20), whereas the value of the ratio for C_2H_4 is exactly twice as high (10 instead of 5) as has been found in the α-ray work of Lind and co-workers. Recent investigations, which have been made since this paper was first written, indicate that the correlation between α-ray work and elec. discharge finds its best basis in the assumption that not the chem. yield per ion pair is the sole controlling factor, but the product of the yield (M/N-ratio) and the mol. ionization. This brings the results for CH_4, C_2H_6 and C_2H_4 in agreement, whereas the results of the C_2H_2 runs now remain out of line, though it is believed that the low values found for C_2H_2 will be raised upon further purification of the gas from acetone or some other inhibitor. C. G. F.

Cracking oil by electricity. HERBERT R. ROWLAND. *Elec. Eng.* **50**, 288–90 (1931).—Low-grade oils formerly wasted are now "cracked" to form gasolines and other highly volatile oils. Some of the problems involved are discussed. Three theories have been advanced as to the part the silent corona discharge plays in the cracking process. It seems feasible to consider an electron moving through an appreciable distance in space and either carrying with it or driving before it a mol. of H_2 in the vapor form. At last a surface is reached which permits no further movement of the oil vapor mol., but which readily absorbs the electron. The violent agitation of the vapors by the silent corona discharge is undoubtedly of prime importance in the complete cracking of the vapors, which facts tend to support the electromech. theory. The gasoline has high anti-knock value and gives greater mileage than "doped" fuels. W. H. B.

Power cable technic. P. DUNSHEATH. *Electrician* **106**, 432–5(1931).—The best preventive of Pb-sheath *corrosion* is the provision of adequate, compounded, waterproof coverings over the Pb. The principal cause, if not the whole explanation, of *ionization* (rise of power factor voltage) in impregnated paper cables is found in the presence of voids, or spaces not filled with solid or liquid dielectric. Sheath and armor effects and armoring of single core cables are discussed. For lower voltages the ordinary routine insulation resistance and pressure tests meet all requirements, but for higher voltages other tests are necessary. Breakdown tests seem more reliable than ionization stability tests, though each has its place. W. H. BOYNTON

A new measurement of the temperature in the arc (V. ENGEL, STEENBECK) **3.** Producing patterns in metals by photography and electrodeposition (Ger. pat. 515,900) **5.** Purifying bitumen, etc., for use in "electrical contrivances" (Brit pat. 339,470) **22.** "Basing cement" for uniting lamp bulbs to bases (U. S. pat. 1,795,746) **18.** Electric system for protecting boilers (U. S. pat. 1,796,715) **14.** Extracting metals (Austrian pat. 121,523) **9.** Alloys for sheathing electric cables (Austrian pat. 121,525) **9.** Float for determination of the specific gravity of accumulator electrolytes (Hung. pat. 101,225) **1.** Treating metals in ladles as in an induction furnace (Brit. pat. 339,579) **9.**

MÜLLER, ERICH: **A Laboratory Manual of Electro-Chemistry.** Translated from 4th ed. by H. J. T. Ellingham. London: Geo. Routledge & Sons, Ltd. 364 pp. 15s. Reviewed in *Chem. Trade J.* 88, 314(1931).

WEJNARTH, AXEL: **Beiträge zur Kenntnis der elektrothermischen Zinkgewinnungsmethode.** Stockholm: Wille Hedbergs Tryckeri Aktiebolag. 146 pp.

Electric batteries. C. DILLGER (trading as Hamburger Batterie-Fabrik C. Dillger) and D. SCHMIDT. Brit. 338,765, March 22, 1929. A battery of the Leclanche type has a depolarizer consisting of a double salt of NH_3 or an amine and Zn or other electropositive metal, such as the double salt of $ZnCl_2$ and methylamine-HCl or *o-m-p*-toluidine-HCl or Zn NH_4 chloride.

Electric batteries. LOUIS F. J. ROUSSEAU. Fr. 37,261, Feb. 21, 1929. Addn. to 668,569 (*C. A.* 24, 1584). Electrolytes of strong acid concn. are immobilized by fibrous masses of animal origin such as wool or felt or by dissolving an appropriate amt. of cellulose in the liquid.

Electric battery. MARIE IRLE NÉE GAUJACQ. Fr. 37,211, July 12, 1929. Addn. to 674,622 (*C. A.* 24, 2677). To prevent the Zn being covered with Cu or like metal resulting from the diffusion of the depolarizing liquid into the liquid which surrounds the Zn, a metallic screen is placed in the layer of sepn. of the 2 liquids. A salt of Hg may be added to the depolarizing liquid, which salt by diffusion comes in contact and amalgamates with the Zn.

Dry batteries. KUNO WOLF. Ger. 515,694, Oct. 25, 1929. The "dry" filling consists of colloidal H_2SiO_3 and concd. H_2SO_4. A 15% soln. of H_2SiO_3 is preferred.

Dry-cell electric-battery assembly. ELMER J. STROHL and EDWARD C. SMITH (to National Carbon Co.). U. S. 1,797,161, March 17. Structural features.

Storage battery. A. G. OWENS. Brit. 339,050, Oct. 9, 1929. Structural features

Storage battery. JOSEPH L. WOODBRIDGE. U. S. 1,796,818, March 17. Structural features.

Storage batteries. SOC. ANON. DES ACCUMULATEURS MONOPLAQUE. Brit. 338,921-2, Jan. 29 and Feb. 26, 1929. Structural features.

Storage-battery hydrometer (attached to the vent plug). CHARLES E. LINEBARGER. U. S. 1,796,379, March 17. Structural features.

Battery container. EDWARD LYNDON. U. S. 1,796,034, March 10. Containers are made of permeable material non-resistant to acids such as pressed wood pulp impregnated with prevulcanized rubber.

Depolarizers for galvanic batteries. NEUE ELEMENT-WERKE GEBR. HAAS & CO. Ger. 515,762, July 11, 1926. A depolarizer is made up by mixing together graphite and soot, compressing the mixt. and then mixing in MnO_2.

Galvanic elements. FIRMA AUGUST ALEXANDER. Ger. 515,693, July 3, 1929. Details of arranging the C rods and metal caps in dry batteries.

Selenium cell. F. H. CONSTABLE and RADIOVISOR PARENT, LTD. Brit. 339,245, Sept. 2, 1929.

Lead accumulator. JOHANN MATUSCHEK. Austrian 121,320, Sept. 15, 1930. The PbO_2 constituting the active mass of the pos. electrode is not exclusively generated during the manuf. of the electrode, but is included in a substantial proportion in the mass from which the pos. electrode or both electrodes is or are to be formed. Other oxides of Pb may be present also, and the mass is preferably supported on unalloyed Pb. Details of the charging are described.

Protecting layer for the electrolytes of accumulators. GY. DIAMANT. Hung. 100,891, Feb. 20, 1929. A layer consisting of loose particles of solid materials is located on the surface of the electrolyte, *e. g.*, charcoal particles impregnated with hydrocarbons or resins. This layer is afterward partly or totally solidified.

Dry rectifier with electrodes coated with metallic oxide. SIEMENS-SCHUCKERTWERKE A.-G. Ger. 515,529, Nov. 19, 1926. Plates of Cu are coated on one side with Cu_2O and on the other with Ag. Cf. *C. A.* 24, 27.

Electrodedeposition of metals such as chromium, etc. HARRY SCHMIDT, GEORG ERLWEIN and MARTIN HOSENFELD (to Metal & Thermit Corp.). U. S. 1,795,512, March 10. Solid adherent coatings are obtained by electrolytically depositing metals such as Cr at a temp. below their m. p. from a fused bath, the point of fusion of which is at least 100° lower than the m. p. of the metal to be deposited and which contains a B compd. such as mixed borates together with a compd. of the metal to be deposited.

Electrodeposition of chromium. WM. S. EATON. U. S. 1,795,481, March 10. The cleaned articles to be plated are immersed in an aq. electrolytic bath, the active ingredients of which consist solely of chromic acid and Na_2CO_3 in soln. in water.

Chromium plating. LEON R. WESTBROOK (to Grasselli Chemical Co.). U. S. 1,795,459, March 10. A bath for Cr plating contains chromic acid in aq. soln. together with a small proportion of the SO_4 radical (which may be supplied by use of Na_2SO_4) and a small proportion of the neg. radical of molybdic or vanadic acid (suitably supplied by use of a molybdate or vanadate).

Electrodeposition of metals such as copper, nickel or cobalt on rotating cylindrical mandrels. S. O. COWPER-COLES. Brit. 338,487, May 15, 1929. Numerous details of app. and procedure are described for the deposition of the metal and its consolidation by the action of rollers which may be formed of glass or of metal such as ferro-Si. The mandrel is preferably of welded steel or iron sheet or turned and polished cast iron, and to allow detachment of the deposit in tubular form the mandrel is first made passive by treatment with HNO_3 and then polished and treated with a stripping prepn. An anode of Pb, C, ferro-Si or other material may be used and various details of electrolyte compns., etc., are given. Deposition of Zn and Ag also is mentioned.

Electrodeposition of metals on rotating mandrels. S. O. COWPER-COLES. Brit. 338,540, May 15, 1929. In a process such as described in Brit. 338,487 (preceding abs.), the surface of the rotating mandrel is prepd. to facilitate detachment of the deposit by forming on it a film of oxide or sulfide or by applying a film of Pb which is then polished with plumbago or other suitable polishing material. The surface of the mandrel is preferably formed of Cu or brass.

Electrodeposition of tin. SIEMENS & HALSKE A.-G. Brit. 338,488, May 16, 1929. Thick, coherent, firmly adhering deposits are obtained in the electrodeposition of Sn from alkali metal stannate or stannite solns., sol. anodes being used, by maintaining the free alkali content in the electrolyte (inclusive of that set free by hydrolysis, but not including alkali metal carbonate) below 1.5%. A Sn concn. of 0.05% or more may be employed, and if the Sn concn. is above 7%, the alkali content must be somewhat higher but should be not more than one-fifth of the Sn content. Cf. *C. A.* **25**, 882.

"White gold" plating. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORMALS ROESSLER (Leo Nowack, inventor). Ger. 515,579, Oct. 15, 1926. Objects to be plated in "white gold" are formed of a ground metal which is given a thin layer of metal which then alloys with the ground metal to form the "white gold" surface. Thus, a degreased 18 c. gold object (Au-Ag-Cu) is nickeled by electrolysis in the usual way. The Ni plated object is then immersed in a fused salt mixt. and heated to 700° for 20 min. This causes the Ni to alloy with the gold to form a "white gold" surface. Further examples are given.

Plating aluminum with other metals. M. K. DE TRAIRUP. Brit. 339,339, Sept. 3, 1929. Al surfaces are prepd. for plating with metals such as Ni, Cu, Ag or Au by a preliminary electrodeposition of an amalgam such as may be deposited from a bath formed of NaOH 200, sodamide 200, $SnCl_2$ 40, $ZnCl_2$ 10, $Hg(NO_3)_2$ 5, KOH 10 and water 20,000 parts.

Electroplating apparatus with a tumbling-barrel. CARL H. HANSEN. U. S. 1,795,336, March 10. Structural features.

Mold for making articles by electrodeposition. G. ROSENQVIST. Brit. 339,428, Oct. 24, 1929.

Liquid seal for gas chambers of electrical precipitation plants. LODGE-COTTRELL, LTD., and L. LODGE. Brit. 338,827, March 4, 1930.

Degasifying electrolytically deposited metals. JULIUS VON BOSSE. U. S. 1,795,-384, March 10. Electrodeposited coatings of metals are freed from absorbed H tending to cause embrittlement of the metal, by subjecting the metal coating to an elec. discharge in a vacuum tube in which the coating is made one of the electrodes.

Drying by electrolysis. N. ALTAI. Hung. 100,547, Sept. 3, 1929. Moisture is eliminated by electrolysis of material in its natural state or after grinding or pressing to briquets.

Electrolytic apparatus for removing salts from liquids. JEAN BILLITER. Austrian 121,039, Aug. 15, 1930.

Aluminum production by electrolysis of fused halide baths. I. G. FARBENIND. A.-G. Brit. 338,668, July 4, 1929. A fused mixt. which may be formed of NaCl 14, KCl 6 and $AlCl_3$ 80% is electrolyzed at a temp. of 100° with a graphite anode and a rotating cylindrical cathode of graphite or metal (a compact deposit being obtained by use of a c. d. of 1 amp. per sq. dcm. or even higher); or a mixt. comprising NaCl 18 and $AlCl_3$ 82% may be electrolyzed at 160° with a W anode and an iron roller cathode. Various details of app. and procedure are described.

Electrolytic refining of aluminum. UKRAINSKII NAUCHNO-ISSLEDOVATELNUII

INSTITUT METALLOV "UKRINMET." Russ. appl. 30,500, July 24, 1928. A complex ammonium aluminum halide is used as electrolyte.

Magnesium. DOW CHEMICAL CO. Brit. 339,504, Dec. 16, 1929. See U. S. 1,749,210 (*C. A.* **24**, 2064).

Recovery of tin. SIEMENS & HALSKE A.-G. Fr. 37,495, Oct. 7, 1929. Addn. to 650,579 (*C. A.* **23**, 3173). In the electrolytic recovery of Sn from Sn residues not contg. plumbite, bismutite or other substances acting in the same way, the electrolysis is carried out without the addn. of colloid after quantitative transformation of all the Sn into stannate form.

Nitrogen fluoride. OTTO RUFF. Ger. 518,202, Feb. 2, 1930. NF_3 prepd. by electrolyzing fused NH_4HF_2, or by interaction of NH_3 and F, is freed from NHF_2 and N_2O by passage over soda-lime at 100°, followed by washing with warm acid KI soln. and fractionating.

Coating metal articles with lead peroxide electrolytically. JOHANNES FISCHER (to Siemens & Halske, A.-G.). U. S. 1,795,941, March 10. Metal articles such as iron or steel are made anodes in an alk. bath contg. Pb and at least one cyanide, sulfocyanide such as KCNS or dimethylglyoxime. The bath is free from heavy metals other than Pb.

Electrolytic condenser. JOSEPH SLEPIAN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,900, March 10. Various elec. and structural features of condensers with film-forming electrodes immersed in an electrolyte are described. Cf. *C. A.* **24**, 1302

Introducing alkali or alkaline earth metals or oxygen into sealed glass vessels. VEREINIGTE GLÜHLAMPEN UND ELECTRICITÄTS A.-G. Austrian 121,033, Aug. 15, 1930. This is effected by electrolyzing the wall of the vessel. A part of the vessel is coated on the inside with a very thin metal layer, which constitutes one electrode, and the coated part is heated and supplied with current. The external electrode may be a fused bath, *e. g.*, a salt of the metal to be introduced into the vessel. Numerous details are given of the application of the method to the manuf. of cathodes for electric discharge tubes and photo-elec. cells. Cf. Austrian 120,121 (*C. A.* **25**, 1710).

Purifying inert gases in electric discharge tubes, etc. VEREINIGTE GLÜHLAMPEN UND ELECTRICITÄTS A.-G. Austrian 121,056, Aug. 15, 1930. Alkali or alk. earth metals are introduced into the vessel contg. the gas by the electrolytic method described in Austrian 121,033 (preceding abst.).

Electric furnaces and electrolytic vats. ALFRED FRANCHINI and PAUL GIROD Fr. 695,216, Aug. 27, 1929. Method of mounting and moving the electrodes is described.

Electric induction furnace. PORTER H. BRACE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,827, March 10. Structural and elec. features.

Electric induction furnace. NEVILLE R. DAVIS (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,842, March 10. Structural features of a furnace, the lining of which has embedded in it a metal cage to effect its heating and drying by the heating from induction.

Electric induction crucible furnace suitable for melting metals. PORTER H. BRACE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,926, March 10. Structural and elec features.

Coreless electric induction furnace suitable for melting metals. NEVILLE R. DAVIS and CECIL R. BURCH (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,934, March 10. A metal conduit is arranged to cool an inductor coil which is adjacent and coextensive in length. U. S. 1,795,935 describes various details of procedure for sintering a desired portion of the lining of an elec. induction furnace.

Electric resistance furnace for heat treatments. SVEN P. AXELL (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,819, March 10. Structural features of a muffle furnace provided with a conveyor.

Electric resistance furnaces and ovens. F. W. CUFFE. Brit. 338,816, Feb. 11, 1930. Structural features.

Electrical and mechanical control system for furnaces such as plural-hearth-tray rotary dumping furnaces. HARLAN S. GANO (to Westinghouse Elec. & Mfg. Co.). U. S. 1,795,945, March 10. Various structural and elec. features are described.

Electrode holder for electric furnace. SIEMENS-PLANIAWERKE A.-G. FÜR KOHLEFABRIKATE. Ger. 518,332, June 27, 1926.

Electric regulating device for ovens for baking lacquered wire. ELECTRICAL RESEARCH PRODUCTS, INC. Ger. 518,078, Nov. 16, 1927. The temp. is regulated in accordance with the hardness of the coating on the wire leaving the oven.

Electrically heating the contents of high-pressure vessels. SIEMENS-SCHUCKERTWERKE A.-G. (Günther Scharowsky, inventor). Ger. 515,944, Aug. 24, 1926.

Electric gas purifiers. METALLGESELLSCHAFT A.-G. (Walter Deutsch and Wilhelm Hoss, inventors). Ger. 515,928, Nov. 30, 1928. An arrangement for preventing damage to the electrodes by sparking is described. Cf. *C. A.* 25, 2061.

Apparatus for electrical precipitation of suspended particles from gases. INTERNATIONAL PRECIPITATION CO. and LODGE-COTTRELL, LTD. Brit. 338,796, Jan. 14, 1930. Structural features.

Apparatus for electrical precipitation of suspended particles from gases. LODGE-COTTRELL, LTD., and L. LODGE. Brit. 338,739, Nov. 29, 1929. Structural features.

Electrical purification of gases such as carbon dioxide. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 338,944, April 17, 1929. Various details are described for use of high-potential rectified a. c.

Use of silent electric discharges to facilitate catalytic gas reactions. FRITZ LECHLER (to International Precipitation Co.). U. S. 1,796,110, March 10. Apparatus and details of operation are described for promoting reactions by the combined action of contact substances and silent elec. discharge, in such manner that the elec. discharge acts not only to promote directly the reaction, but also to create an elec. wind in the gas so as to bring the gases into more effective contact with the contact substance. The process may be applied to the promotion of any reaction between materials in the gaseous phase, which is facilitated or promoted by the presence of a catalytic contact substance, for example to the oxidization of SO_2 to form SO_3 as in the contact process of H_2SO_4 manuf. or to the chlorination or hydrogenation of hydrocarbons or other org. gases.

Spark-discharge apparatus for producing a bleaching gas for corn, etc. FRITZ STUFF. Ger. 518,201, June 28, 1929.

Apparatus for heating "lyes and acids" by electrical resistances. VEREINIGTE ALUMINIUM-WERKE A.-G. Brit. 338,740, Nov. 29, 1928. Tubular coils (suitably formed of Pb) serve as elec. resistances and communicate with the interior of the vessel, the contents of which are to be heated. These coils are placed around the vessel, and are in turn surrounded by heat insulating material.

Protection of electrical apparatus such as switches, transformers, choke coils, motors or dynamos. MAX BUCHHOLZ U. S. 1,796,746, March 17. A cell, the wall of which is of such a degree of porosity as will permit osmotic diffusion of the products of decompn. occurring in the insulation of the app. such as a transformer under abnormal conditions, is assocd. with a device such as an alarm device which is influenced by products thus passing through the wall of the cell. Various structural details are described.

Electric ozone generator. MARIUS P OTTO U. S. 1,796,214, March 10. Structural features.

Special loading of long submarine cables. V. E. LEGG (to Electrical Research Products, Inc.). Brit. 339,049, Nov. 8, 1928. End sections of a cable are provided with loading of greater thickness than the central portion and which has a lower hysteresis loss, lower resistivity and a higher constancy of permeability for a wide range of magnetizing forces than the material of the central section loading. The central portion of the cable may be loaded with an alloy contg. Ni 45, Fe 23, Co 25, Mo 7, Si 0.47% or Ni 55, Fe 34 and Cr 11%. The end sections may be loaded with an alloy contg. Fe 27, Ni 45, Co 25, Mo 2.5 and Mn 0.35%.

Cut-out for series lamps. DANIEL S. GUSTIN and EWALD DIETZ (to the Canadian Westinghouse Co., Ltd). Can. 309,241, Mar. 10, 1931. A cut-out medium for series lamps is produced by mixing powd. Cu with sodium silicate and dehydrating the mixt., then mixing the dehydrated mixt. with sodium silicate and applying pressure to produce a compact mass.

Electric incandescent lamp. LLOYD D. LOCKWOOD (to Westinghouse Lamp Co.). U. S. 1,795,785, March 10. Devices such as incandescent lamps are flushed with water gas during baking, in order to eliminate surface oxides on the metal parts. Cf. *C. A.* 24, 3958.

Decoration of electric incandescent lamps. K. MENESDORFER. Hung. 101,377, Nov. 12, 1929. Cellulose varnish is sprayed on the lamp as a base, and the decoration is produced by spraying various paints through stencils. The decoration thus produced does not crack off.

Coating for lamp bulbs. ALBERT F. LINDSTROM (to The Canadian Westinghouse Co., Ltd.). Can. 309,250, Mar. 10, 1931. A green coating compd. for the interior of lamp bulbs comprises sodium silicate, kaolin, hydrated chromic oxide and boric acid.

5—PHOTOGRAPHY

E. P. WIGHTMAN

Further advances in photographic science. S. O. RAWLING, *Science Progress* 25, 465–75(1931).—A review is given (with a bibliography of 23 references) of recent work on the chemistry of the photographic emulsion. JOSEPH S. HEPBURN

Formation of photographic images on cathodes of alkali metal photoelectric cells. A. R. OLPIN AND G. R. STILWELL. *J. Optical Soc. Am.* 21, 177–81(1931); cf. *C. A.* 24, 5614.—Both neg. and pos. photographic images on the cathodes of K and Na photoelec. cells in a vacuum have been obtained by focussing an image of the object to be photographed on the cathode during the treatment with a suitable dielectric. The necessary optimum constitution of the surface structure will thus exist though perhaps only momentarily. The images are well defined and can be permanently "fixed" by proper treatment with various materials such as S vapor, air, O and H in the ratio of 9 to 1, HF and Br. The photoelec. sensitivity of the exposed areas decreases approx. 30% during the formation of the image. There appears to be little difference in the sensitivity of the cathode area bearing the image and neighboring area after the image has been permanently fixed. The effect is undoubtedly photochem. but the great variety of materials which can be used in treating the exposed surfaces complicates the chemistry of the phenomenon. W. VANSELOW

Depression of density produced by the presence of bromide in the developer of photographic emulsions exposed to light and to x-rays. A. P. H. TRIVELLI AND E. C. JENSEN. *J. Franklin Inst.* 211, 335–47(1931).—The density depressions of sol. bromide in the developer were detd. with 2 different emulsions for light and for x-ray exposures with hydroquinone and with pyrogallol developer. Abegg's theory of the action of sol. bromide in the developer was the best explanation of the results obtained. This theory was connected with the speck growth theory of the latent image, and the results obtained were explained on the basis of the size and the distribution of the specks. It was shown that there are 2 depression factors: (1) The difference in sizes of developable centers formed by exposure will, with sol. bromide, give a greater density depression for light than for x-ray exposures. (2) The distribution of the developable centers throughout the thickness of the photographic layer will give, for light, a smaller density depression with sol. bromide than for x-ray exposures. A. P. H. TRIVELLI

The question of the metallic ("Mr") silver content and germ formation in photographic emulsions. H. ARENS AND J. EGGERT. *Z. wiss. Phot.* 28, 178–90(1930) P. O. P. emulsions, according to Valenta, increase their amt. of free Ag with age For ordinary photographic layers the results are not const., which shows that the $Ag_2S_2O_3$ complex is not entirely separable from metallic Ag, so that Weigert and Lühr's data (*C. A.* 23, 4900) are too high and consequently also the previous data of the authors A. P. H. TRIVELLI

Cement for films (Hung. pat. 100,689) 23.

HIBBERT, L. J.: **A Manual of Photographic Technique.** 2nd ed. London: Pitman. 133 pp. 2s. 6d., net.

WALL, E. J.: **The Dictionary of Photography.** 12th ed., revised by F. J. Mortimer. London: Iliffe. 681 pp. 7s. 6d., net.

Color photography. B. E. LUBOSHEZ. Brit. 339,511, Dec. 23, 1929. Various details are described of a color filter used with lenticular films.

Color photography. J. N. GOLDSMITH, T. T. BAKER, C. BONAMICO and SPICERS, LTD. Brit. 339,238, Aug. 1, 1929. In the production of regular pattern multicolor screens by means of dye-repellent resists, the dyes in a non-penetrative condition or medium are applied to intermediate surface layers only of a film support which may be formed of celluloid, cellulose acetate or other suitable cellulose ester or ether compn.; *e. g.*, a powd. dye or finely divided dyed substance may be rubbed or spread on the film, or a dye such as cochineal in suspension or a dye in a viscous soln. such as castor oil or gum arabic soln. may be applied. Cf. *C. A.* 25, 1748.

Color photography. MULTICOLOR FILMS, INC. Brit. 339,323, June 4, 1929. Fixed Ag images are treated with a basic dye bath and then with a U toning and mordanting bath, in a process for producing color films having color component images on opposite sides which are simultaneously printed in register from color component nega-

tives. The printed positive is developed, fixed and washed and that side bearing the images printed from the orange-red negative is toned blue by application to that side only of an Fe toning soln. which may be formed from ferric ammonium oxalate, $K_3FeC_6N_6$, NH_4Cl and HCl. The U toning bath may comprise K oxalate, U nitrate, $K_3FeC_6N_6$ and HCl. Various details and modifications of procedure are described.

Dye-impression color photography. J. E. THORNTON. Brit. 339,296, July 3, 1929. In producing 2-color pictures by dye-impression printing, a duplex dye-printing plate is prepd. as described in Brit. 339,321 having upon its composite faces a pair of dye images of complementary character, produced by exposing in a camera from one side only a sensitive film bearing complementary color-sensitive emulsions on opposite sides with assocd. light filters, developing the images, treating them to render the gelatin dye-repellent in proportion to its Ag content, and dyeing with complementary colors the gelatin which remains dye-receptive; also, pos. images are printed simultaneously from the duplex plate as described in Brit. 339,319, by pressure-contact upon 2 sheets of dye-absorbent non-sensitive material provided with registration holds and placed one on each side of the duplex plate; and the printed dye positives are cemented together in register and face to face. Numerous details of procedure are given both in this specification and in Brit. 339,319 and Brit. 339,321.

Screens for color photography. HAROLD WADE. Ger. 518,066, Jan. 25, 1929. See Brit. 322,432 (*C. A.* **24**, 2681).

Screens for color photography. ANTON RYSAVY and ALOIS GRÄF. Austrian 120,858, Aug. 15, 1930. The screens are prepd. from fabrics woven from colored fibers, each fiber comprising a no. of differently colored filaments twisted together. Various methods of prepg. the screens are described.

Photographic films. I. G. FARBENIND. A.-G. (Hermann Lummerzheim, inventor). Ger. 515,776, Dec. 23, 1928. Addn. to 487,586 (*C. A.* **24**, 1808). A roll film with opaque ends which are not affected by the developing bath, is coated with a layer of dye soln. in aq. or org. solvents which is opaque to actinic rays.

Photographic roll films. I. G. FARBENIND. A.-G. Brit. 338,741, Nov. 29, 1928. The sensitive layer of a roll film with a protective paper backing is covered with transparent foil (which may be made of gelatin, regenerated cellulose, a cellulose ester, ether or ether-ester) colored to serve as a light filter when the film is exposed. Cf. *C. A.* **25**, 887.

Roll films from cellulose acetate. KODAK-PATHÉ SOC. ANON. FRANÇAISE. Ger. 515,533, Apr. 20, 1927. The back of the film is colored by coating with an alc. soln. of magenta and aurine, with or without addn. of naphthalene green.

Photographic negatives. MAX WOLFRAM and EDWIN SCHAFFER. Ger. 515,584, Dec. 20, 1929. Film negatives which can be easily detached from their glass, etc., carriers are prepd. by giving the transparent carrier a layer of rubber, gelatin or celluloid soln., before giving them the light-sensitive layer.

Paste for over-exposed negatives. JOSEF PFEIFFER. Austrian 121,139, Sept. 15, 1930. A paste for application to portrait and like negatives showing extremes of contrast comprises finely sifted kieselguhr 1 and tallow 3 parts, with a little $PhNO_2$ or wintergreen oil. For landscape and like negatives, only 1 part of tallow is taken, and coarse kieselguhr or tripoli is used instead of fine kieselguhr. The paste is rubbed onto the over-exposed parts, and acts mechanically by removing some of the excess of reduced Ag.

Photographic toned prints. RICHARD MICHEL. Austrian 121,141, Sept. 15, 1930. In the prepn. of toned prints on development papers contg. Ag salts by bleaching out, exposing and redeveloping, prints showing two or more tones are obtained by using a bleaching bath contg. an iodide and at least one other halide. A suitable bath is prepd. by adding 0.25–1.5 cc. of 1% KI soln. to a soln. of KBr 2, $CuSO_4$ 2 and citric acid 2 g. in water 100 cc. Addnl. details are given.

Photographic papers. CHARLES EMDÉ. Fr. 37,318, Aug. 8, 1929. Addn. to 676,317 (*C. A.* **24**, 2682). Blue variamine salt in aq. soln. is used as the diazo compd. to apply on the supports. A little sulfate of Ni or Al and a few g. of an org. acid may be added.

Apparatus for developing photographic paper by use of ammonia. KNUD MURCK (to Charles Bruning Co.). U. S. 1,795,344, March 10. Structural features.

Photographic layers. I. G. FARBENIND. A.-G. (Walter Frankenburger and Georg Rössler, inventors). Ger. 518,064, Jan. 23, 1929. Light-sensitive substances and insensitive substances are suspended together in a colloidal material or a soln. thereof, and the suspension is distributed onto a support in the form of fine particles, *e. g.* by atomizing the suspension into a hot atm. so that a fine powder is obtained,

which is spread on the support. Different light-sensitive substances may be applied to a common support. Thus, for the prepn. of layers useful for color photography, three gelatin emulsions are prepd., each contg. a silver halide sensitive to light in a primary color and a correspondingly colored pigment. The emulsions are atomized, and the resulting fine powders are mixed and applied to the support. Details are given also of the prepn. of layers for making anaglyphs.

Anti-halation layers for photographic plates and films. I. G. FARBENIND. A.-G. (Hermann Dürr and Wilhelm Schneider, inventors). Ger. 518,363, Feb. 18, 1930. These layers contain dyes obtained by condensing a substituted aromatic aldehyde with a quaternary heterocyclic base contg. a reactive Me group. Such dyes are irreversibly decompd. by the developing solns. A suitable dye is obtainable from quinaldine methyl bromide and *p*-dimethylaminobenzaldehyde, or from quinaldine methyl sulfate and piperonal.

Printing on photographic layers. I. G. FARBENIND. A.-G. Fr. 37,317, Aug. 12, 1929. Addn. to 671,999 (*C. A.* **24**, 2072). The 2 ends of the band of film are provided on the whole surface of the side of the layer with a color (obtained by the method of the prior patent) impermeable to actinic rays and insol. in photographic treating liquid

Photographic emulsions. V. L. MAKAROV. Russ. appl. 68,855, April 23, 1930. Photographic emulsion is sprayed on paper or plates with NH_3 or AcCl or with air satd. with these compds.

Thioxanthonium or selenoxanthonium dyes for the preparation of photographic bleach-out layers. I. G. FARBENIND. A.-G. (Bruno Wendt and Alfred Fröhlich, inventors). Ger. 518,065, Mar. 1, 1930. Examples are given.

Photographic etching. ALEX B. DAVIS (to Keystone Watch Case Corp.). U. S 1,797,210, March 17. A photographic resist is prepd. by treating a hydrophobic colloid such as asphalt with a sensitizer comprising a soln. of S chloride in CS_2 in a single step, removing the solvent, washing the treated colloid with an ether to increase its sensitivity to light, and dissolving in benzene. U. S. 1,797,211 describes forming a light sensitive hydrophobic colloid by the reaction of a CS_2 soln. of an asphalt-base material with a CS_2 soln. of S chloride *en masse*, removing non-reacted light-sensitive portions, placing a film of the light-sensitive residue on an object to be etched, projecting a design on it, developing and etching. Cf. *C. A.* **24**, 2390.

Producing patterns in metal by photography and electrodeposition. OLIVE MILLER NÉE ASSINDER and FREDERICK MILLER. Ger. 515,900, Mar. 23, 1930. A photographic plate having a sol. light-sensitive layer is exposed behind a diapositive of the pattern An elec. conducting material in powder form is allowed to accumulate on the unexposed parts and this deposit is coated with an aq. insol. membrane, to which it adheres. The coatings are then removed and the conductor deposit of the desired pattern plated galvanically with metal.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Coördinated compounds of the alkali metals. III. FREDERICK M. BREWER *J. Chem. Soc.* **1931**, 361–8; cf. *C. A.* **20**, 740.—The coördinated compds. of the alkali metals with salicylaldehyde (I) are prepd. The covalency nos. established for the metals in these compds. are: Li, 4; Na, 4; K, 4 and 6 (the 6-covalent compd. is formed only with difficulty); Rb, 4 and 6 (only here the 6-covalent compd. is definitely more stable); Cs, 4 and 6 (only a slight difference in the stability of these 2 compds.). Of the compds. prepd. those contg. 4-covalent Na or K are by far the most stable The compd. contg. 4-covalent Li ($C_7H_5O_2Li$, $C_7H_6O_2$, pale yellow solid) was obtained when dry LiOH was added to I and the mixt. warmed gently. Both the 4-covalent compds. of Na and K with I have been prepd. by Hantzsch (*Ber.* **39**, 3089(1906)). Attempts to prep. the compd. contg. 6-covalent Na were unsuccessful. The compd. contg. 6-covalent K ($C_7H_5O_2K$, $2C_7H_6O_2$, pale yellow feathery crystals) was obtained by adding concd. KOH soln. to I, dissolving the resulting solid in a mixt. of alc. and I, crystg., and washing with alc. A mixt. of the compds. contg. 4- and 6-covalent Rb was obtained as almost colorless crystals when powd. Rb_2CO_3 was dropped into warm I. On heating these crystals under reduced pressure a residue of *rubidium salicylaldehyde* ($C_7H_5O_2Rb$) was obtained. The compd. contg. 4-covalent $Rb(C_7H_5O_2Rb$, $C_7H_6O_2$, colorless crystals which melt indefinitely with decompn.) was prepd. by dissolving Rb_2CO_3 in a min. of H_2O, adding I contg. a small quantity of alc., warming until the CO_2 evolution ceases, cooling, recrystg. from alc. and washing with Et_2O. The compd.

contg. 6-covalent Rb ($C_7H_5O_2Rb$, $2C_7H_6O_2$, colorless feathery crystals) was obtained (*a*) by allowing the product of recrystn. in the preceding to stand in I for several hrs in the cold, and (*b*) by recrystg. from I contg. a min. of alc. to effect soln. below 100°. The compd. contg. 6-covalent Cs ($C_7H_5O_2Cs$, $2C_7H_6O_2$) was prepd. by carrying out the initial reaction without alc., recrystg. using sufficient H_2O to keep any excess Cs_2CO_3 in soln., filtering, washing with H_2O, keeping in I for several hrs., filtering and washing with alc. The compd. contg. 4-covalent Cs ($C_7H_5O_2Cs$, $C_7H_6O_2$, pale yellow cryst. solid which melts with decompn. at about 165°) was prepd. from the initial product by (*a*) washing with Et_2O until a slight decolorization begins, or (*b*) pptg. from an alc. soln. with Et_2O. In the compds. prepd., Li alone forms a true coördinated hydrate. *Rubidium benzoylacetone* ($C_{10}H_9O_2Rb$, $C_{10}H_{10}O_2$, bright yellow plates which melt to a red liquid at 131°) was prepd. by dissolving Rb_2CO_3 in an excess of molten benzoylacetone, and recrystg. from hot toluene. J. BALOZIAN

Reactions in the solid state at elevated temperatures. VIII. Reactions of columbium pentoxide and tantalum pentoxide with metallic oxides and alkaline earth carbonates. WILHELM JANDER AND HERMANN FREY.. *Z. anorg. allgem. Chem.* **196**, 321–34(1931); cf. *C. A.* **24**, 4974.—This work involved a study of the reactions between BaO, SrO, CaO, MgO, ZnO, CuO, $BaCO_3$, $SrCO_3$ and $CaCO_3$ on the one hand and Ta_2O_5 and Cb_2O_5 upon the other hand. Heating curves, percent decompn. and temp.-pressure curves were detd. by different methods. The following figures were given for the temp. at which a perceptible reaction commenced: MgO + Ta_2O_5 (485°), ZnO + Ta_2O_5 (500°), MgO + Cb_2O_5 (500°), ZnO + Cb_2O_5 (520°), $BaCO_3$ + Ta_2O_5 (480°), $SrCO_3$ + Ta_2O_5 (410°), $CaCO_3$ + Ta_2O_5 (400°), $BaCO_3$ + Cb_2O_5 (450°), $SrCO_3$ + Cb_2O_5 (420°) and $CaCO_3$ + Cb_2O_5 (380°). The following compds. were prepd. for the first time: $2BaO.Ta_2O_5$, $4BaO.Ta_2O_5$, $2SrO.Ta_2O_5$, $4SrO.Ta_2O_5$, $4CaO.Ta_2O_5$, $BaO.Cb_2O_5$, $4BaO.Cb_2O_5$, $SrO.Cb_2O_5$, $4SrO.Cb_2O_5$ and $5CaO.Cb_2O_5$. $2CaO.Ta_2O_5$ and $2CaO.Cb_2O_5$ were also obtained. H. STOERTZ

Obtaining anhydrous aluminum chloride from natural aluminum-containing raw materials. VICT. I. SPITZVIN AND O. M. GVOSDEVA. *Z. anorg. allgem. Chem.* **196**, 289–311(1931).—The conditions for obtaining anhyd. $AlCl_3$ from kaolin earth and argillaceous earth-coal mixts. were studied. Cl and HCl gas were used as chlorinating agents. The raw material must first be freed of Fe by heating in a current of HCl gas at 400–900°; wood charcoal was the most successful form of C used. In the treatment with HCl gas an excess of C is essential, while with the treatment with Cl this is not necessary, nor is gas velocity of great influence. In this reaction, silicic acid is likewise chlorinated. Thermodynamic considerations indicate that Al_2O_3 acts as a catalyst in promoting the chlorination of SiO_2. The chlorination reaction begins at 600° and is accelerated at higher temps., the most favorable conditions occurring at about 800°. In an effort to diminish the chlorination of SiO_2, HCl was added to the gas, but this likewise decreased the yield of $AlCl_3$. $SiCl_4$, however, when added to the Cl, suppressed the chlorination of SiO_2 without appreciable effect upon the reactivity of the argillaceous earths. H. STOERTZ

Crystallization of copper from molten cuprous chloride. V. SIHVONEN. *Z. Elektrochem.* **37**, 80–2(1931).—Cu crystd. out in dendritic form in the cooler portions of CuCl unevenly heated to 370–470°. The reaction taking place in the melt was $2CuCl \leftrightarrows Cu + CuCl_2$. G. T. MOTOK

Some copper mercaptides and their reaction with carbon disulfide. W. E. DUNCAN, EMIL OTT AND E. EMMET REID. *Ind. Eng. Chem.* **23**, 381–4(1931).—By the interaction of solns. of mercaptides in C_6H_6 with an aq. soln. of $(AcO)_2Cu$, the complete series of cuprous mercaptides from Me to *n*-nonyl and from *sec*-Pr to *sec*-nonyl was prepd. They react with S in a way similar to that observed for the Pb salts (*C. A.* **24**, 4758). They add CS_2 to form alkyl cuprous trithiocarbonates. No basic Cu mercaptides were formed. LOUISE KELLEY

Hydrogen fluoride and its solutions. J. H. SIMONS. *Chem. Reviews* **8**, 213–35 (1931); cf. *C. A.* **25**, 861.—S. discusses the following: the prepn. of anhyd. HF; the technic of handling HF; the chem. and phys. properties of HF; its mol. structure; the soly. of substances in anhyd. liquid HF, which acts as a polar solvent very similar to H_2O; the conductance of solns. in anhyd. HF of salts, inorg. and org. acids, alcs., Me_2CO and Et_2O; the system: C_6H_6–HF. LOUISE KELLEY

The decomposition of Carborundum by a mixture of hydrofluoric and nitric acids. N. SLOMNESCO. *Compt. rend.* **192**, 361(1931).—Finely divided SiC is decompd. by treatment with concd. HF and a little concd. HNO_3 for a period of 15 days. The liberation of gas marks the progress of the reaction. F. W. LAIRD

Thiophosgene and some of its strange derivatives. ALBERT HUTIN. *Rev. gén.*

mat. plastiques **7**, 95–7(1931).—A few of the reactions of $CSCl_2$ are very briefly outlined.
A. PAPINEAU-COUTURE

Preparation of hydrocyanic acid by oxidation of ammonium thiocyanate or thiocyanic acid with nitric acid. W. GLUUD AND K. KELLER. *Ber. ges. Kohlentechnik* **3**, 395–419(1931); cf. *C. A.* **24**, 2684.—In the oxidation of NH_4CNS with HNO_3, to get a good yield of HCN it is necessary to count on a 10% loss of NH_3 and NO, because of the fact that HNO_3 is formed, which in turn forms NH_4NO_3, and this is decompd. into N and H_2O. If NH_4CNS, however, is first converted into HCNS by treatment with H_2SO_4, oxidation of the free acid to HCN can be brought about without this loss of N. The reaction proceeds according to the equation: $HCNS + 2HNO_3 \longrightarrow HCN + H_2SO_4 + 2NO$. A study made of the most favorable conditions of concn. showed that if a soln of HCNS contg. about 20 g. per 100 cc. is treated with HNO_3 soln. contg. about 40 g. per 100 cc., a 95% yield of HCN can be obtained with very little loss of NO or HNO_3. This represents 3–4 moles of HNO_3 per mole of HCNS, or a 100% excess of HNO_3. Expts. were made on a larger scale with the following results: To manuf 1000 kg. of HCN from 17% HCNS soln., 14,350 kg. of the HCNS soln., 13,950 kg. of HNO_3 (52.8%), 8.4 cu. m. of reaction water, 43.8 cu. m. of cooling H_2O and 10 kw hrs. of elec. energy were required. This yielded, in addn. to the HCN, 2300 kg. of NO gas and 3820 kg. H_2SO_4
H. STOERTZ

Constitution of cyanogen halides. II. Refractometric study of cyanogen chloride and iodide. ENRIQUE V. ZAPPI. *Bull. soc. chim.* [4], **47**, 537–45(1930).—See *C. A.* **24**, 5248.
E. M. SYMMES

Refractometric study of chromic acid reduction. GEORG GRASSER AND HIROSHI OHOKI. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. 2, 289–94(1930).—Changes in *n* accompanying reduction by a wide variety of reducing agents are described.
H. B MERRILL

Liquid hydrogen sulfide as a reaction medium. JOHN A. WILKINSON. *Chem. Reviews* **8**, 237–50(1931).—Liquid H_2S is discussed in regard to the following points: its prepn.; its phys. properties; its action as a solvent for org. and inorg. substances; conductance of solns. of org. substances, particularly thiol and dithio acids, and inorg. substances in liquid H_2S; thiohydrolysis, or the metathetical reaction of H_2S with other substances, such as the chlorides of P, As, Sb, Bi and esters of CH_3COSH; its reaction with various substances, such as liquid SO_2, CaO, CaC_2, nitriles and Grignard reagents.
LOUISE KELLEY

The polysulfides of the alkali metals. II. Lithium. THOMAS G. PEARSON AND PERCY L. ROBINSON. *J. Chem. Soc.* **1931**, 413–20; cf. *C. A.* **24**, 4724.—An attempt to prep. Li polysulfides from soln. (by the action of S on Li_2S in alc., alc.-H_2O and H_2O solns. (I), and on LiHS in anhyd. alc. soln. (II)) and by dry methods (by the action of S on Li_2CO_3 (or LiOH) (III), and on molten Li (IV)). In I polysulfide solns. are obtained, which, however, could not be crystd. In II the primary product is Li_2S_4, providing the S is in sufficient quantity, as demanded by $2LiHS + 3S = Li_2S_4 + H_2S$. On crystn. of the resulting soln. at room temps. $Li_2S_4.2C_2H_5OH$ is obtained, while at the b. p. $Li_2S_2.C_2H_5OH$ is obtained. When S is used in smaller quantity than is demanded by the equation a mixt. of Li_2S_4 and LiHS results. In III a reaction first starts at 200° giving thiosulfate and polysulfide; at 400° some S and thiosulfate are formed, and at 700° polysulfide, sulfate and small quantities of thiosulfate and sulfite are produced. In IV there is no reaction until 0.5 g. atom of S has been added to 1 g. atom of Li, when it takes place with explosive violence, giving principally Li_2S and small quantities of polysulfide. A study of the system Li_2S–S shows that at atm. pressure only Li_2S (stable at its m. p., 900–975°) and Li_2S_2 (slightly decompd. at its m. p., 369.5°) are stable.
J. BALOZIAN

Autoxidation of phosphorus in carbon tetrachloride solution. BRUNO BLASER. *Ber.* **64B**, 614–9(1931).—Besson (*Compt. rend.* **125**, 1033(1897)) found that when dry air was conducted through suspensions of colorless P in CCl_4 there was formed a pale yellow ppt. from which he obtained P_2O. Blaser has studied this reaction quantitatively, using suspensions of finely divided P and an app. similar to that of Willstatter (*C. A.* **9**, 308). With absorption of O, a pale yellow, voluminous ppt. began to sep. The velocity of oxidation was found to depend very much upon the temp. and the purity of the solns. Analysis of the product gave a P:O ratio of 2:3. The same product was obtained when P was used in excess. The compd. is not P_4O_6, but is probably a new trioxide, $(P_2O_3)_x$. Its lack of color and the fact that no P can be extd. from it with solvents indicate that it does not contain impurities; yet its lack of the essential outward signs of homogeneity—m. p., b. p., crystal form and soly.—demands further expts. to prove that it is a chem. individual. The new compd. was very hygroscopic

Dried *in vacuo* it became white. It did not decomp. at 100° *in vacuo;* at a higher temp. it decompd. but did not melt. In air at room temp. the white compd. turned yellow and smelled of H phosphide; at a higher temp. the yellow portions became red and P was formed. When some of the compd., suspended in CCl_4, was added carefully to cold H_2O, a yellow ppt. was obtained which was apparently identical with the P_2O described by Besson. LOUISE KELLEY

The nature of hydrates of iron oxide. E. YA. RODE. *J. Russ. Phys.-Chem. Soc.* 62, 1443–52(1930).—An investigation was made of temp.-dehydration curves of artificially prepd. iron oxide gel, of samples of granular lake-ore (Lake Pialo, Olonetzk Gov.), xanthosiderite, brown ore (Ural, Bakal) and of göthite. The results agree with previous investigations in regard to the existence of 3 classes of natural hydrates of iron oxide, α-, β- and γ-. S. L. MADORSKY

The mechanism of the formation of nitric esters. ROBERT C. FARMER. *J. Soc. Chem. Ind.* 50, 75–8T(1931).—F. discusses "pseudo acids," as designated by Hantzsch (*C. A.* 17, 2983), and shows that esterification is a property of the pseudo form and is complementary to the acidic or salt-forming function. Dil. HNO_3 solns. contain only small quantities of pseudonitric acid (I); HNO_3 solns. more concd. than 78% (HNO_3.-H_2O) contain large amts. of I. Addn. of large amts. of H_2SO_4 may decrease the amt. of I, on account of the formation of nitronium sulfate, $(HO)_3N(SO_4H)_2$. F. shows that formation of cellulose nitrate occurs with HNO_3 of above 78% concn. in the absence of H_2SO_4, or with concd. HNO_3 in the presence of P_2O_5 or N_2O_5. F. states that the H_2SO_4 used in nitrations does not have the "pioneering" action of first forming sulfates, but acts only in dehydration. The formation of cellulose nitrate takes place best when about 10% of H_2O is present. With less than this, or in the presence of more than the usual amt. of H_2SO_4, the nitrating action is suppressed, because of the formation of nitronium sulfate. The fact that with mixed acid principally nitrates are formed, the difficulty of formation of sulfuric esters, and the use of alkyl sulfates in alkylation are explained by the reluctance of H_2SO_4 to form the pseudo acid. It is pointed out that the nitration of aromatic compds. is a function of the I present, and is suppressed except at higher temp. where nitronium sulfate is unstable, by the use of large proportions of H_2SO_4. Numerous references are given to the literature on pseudo acids and nitration of cellulose. G. R. YOHE

Contribution to the ebullioscopic study of complexes formed by the halides of cadmium and the corresponding alkaline halides. MLLE. O. HUN. *Compt. rend.* 192, 355-6(1931); cf. *C. A.* 24, 5251.—Evidence is presented indicating the formation of $(NH_4)_2CdCl_4$, $(NH_4)_2CdBr_4$ and Na_2CdI_4. For the chlorides and iodides the stability of these complexes decreases in passing from K to NH_4 to Na, while in the case of the bromides there is an inversion between Na and NH_4. The affinity of these different complexes increases for the same alkali in going from Cl to Br to I. F. W. L.

Nitroso- and isonitrosoferropentacyanide derivatives from nitroprussiates. L. CAMBI WITH A. CAGNASSO AND T. RICCI. *Gazz. chim. ital.* 61, 3–13(1931).—The present paper deals with the ferropentacyanides which are formed by condensation of alk nitroprussiates with substances which contain $:CH_2$ groups with mobile H. New reactions between nitroprussiates and aliphatic NO_2 compds., cyanoacetic acid esters, $PhCH_2CN$ and its derivs. and indole, which are described, confirm the mechanism of the reactions and the structure of the colored complexes already suggested by C. (cf. *C. A.* 7, 2551; 9, 451; 21, 1941), and data based on an x-ray examn. of aq. isonitrosoferropentacyanide derivs. of MeAc, acetylacetone, PhAc, $AcCO_2H$ and indole confirm the structure of the complexes. $EtNO_2$ (2.37 g.) added to satd. K nitroprussiate (8.79 g.) in MeOH, cooled to 0° in an inert atm., EtOK (from 2.34 g. of K) added, the pptd. salt (which changes immediately from red to greenish gray) sepd. in an inert atm., dried, washed with MeOH and then with abs. Et_2O, dried *in vacuo*, dissolved in very dil. H_2SO_4, extd. with Et_2O, evapd. and the residue recrystd. from $CHCl_3$, yields ethylnitrolic acid, m. 81° (decompn.). The same procedure was used with Na nitroprussiate (7.83 g.), $NCCH_2CO_2Et$ (3.39 g.) and NaOEt (from 1.38 g. of Na). The bright red salt when dried became yellow, and it also turned yellow in contact with water. The dry salt was decompd. as before, the product was extd. with Et_2O and purified from C_6H_6, which yielded $NCC(:NOH)CO_2Et$ (cf. *Ber.* 42, 736 (1900)). With $PhCH_2CN$, the Na salt formed in abs. MeOH is red and is still more unstable than the preceding ones, changing to yellow. Decompn. as before yields an oxime which m. 105° and which after again solidifying m. 129°, probably as a result of isomerization. The compd. which m. 105° also m. 129° after recrystn. from water. It is therefore PhC(:NOH)CN (cf. Zimmermann, *J. prakt. Chem.* [2], 66, 361(1855)). The yield is 100%. Under the same conditions, p-$O_2NC_6H_4CH_2CN$ forms a dark red complex compd. which

changes rapidly to green. Decompd. and dried, it forms an oxime, $C_8H_6O_2N_3$, m. 95°, which confirms the data of Zimmermann (*loc. cit.*) for *p*-$O_2NC_6H_4C(:NOH)CN$. Similar results were obtained with other derivs. of $PhCH_2CN$. The yields of isonitronitrile in all cases were 85%, based on the nitroprussiate. Even in dil. EtOH, indole condenses with nitroprussiates, with formation of intense blue complexes. K (0.85 g.) in abs. MeOH (35 cc.) added to K nitroprussiate (2.93 g.) and indole (1.17 g.) in abs. MeOH (50 cc.), and the product washed with MeOH and abs. Et_2O yields the *complex salt* $K_4[C_8H_6ON_2Fe(CN)_5]$, probably contg. the residue of nitroso- or isonitrosoindole. It is violet-black and strongly hygroscopic, and its concd. aq. solns., which are violet, become indigo-blue when dild., as a result of the formation of the *acid salt* $K_3[C_8H_7ON_2Fe(CN)_5]$, which is also deliquescent and is stable in water. Decompn. did not lead to well-defined stable complexes. Under the same conditions as in the prepn of $K_4[C_8H_6ON_2Fe(CN)_5]$, α-methylindole gives a reddish *product* which was not identified. β-Methylindole does not react, which makes it probable that in the formation of $K_4[C_8H_6ON_2Fe(CN)_5]$ and the reddish product above, the NO group enters in the β-position of indole, as has been verified by Angeli in the reaction of alc. nitrites. The results of the x-ray examn. are shown graphically. The examn. was limited to the visible field because of the tendency to decompn. The greater stability of $K_3[C_8H_7ON_2Fe(CN)_5]$ allowed measurements in the ultra-violet region. With MeAc, acetylacetone and $AcCO_2H$, the salts prepd. in water were compared with aq. solns. of the same salts prepd. in abs. MeOH. For comparison, the results with the PhNO complex (cf. Cambi and Ricci, *C. A.* **20**, 1769; **24**, 4231) are also given. The complex salts of $AcCO_2H$, PhAc and indole when in dil. aq. soln., corresponding to the acid salts, show absorption bands similar to that of the pentacyanide from PhNO, *viz.*, from $\nu = 490 \times 10^{-12}$ to 640×10^{-12}. Because of the displacement caused by various radicals united to the N of the NO group, this band is probably evidence of the similar chromophore group in the salts in question. The results show that alcoholates do not, as do alkalies, transform nitroprussiates into nitritocyanides, and that when the reaction can be carried out in water, the same products are obtained as in MeOH (except for $(H_2N)_2CS$ and arylhydroxylamines, cf. C., *C. A.* **24**, 4231). *The structure of the isonitrosoferropentacyanide derivs. of nitroprussiates.* A detailed discussion of the structural problem is included, based both on the previous and present expts. of C. and on expts. by others (cf. C., *loc. cit.*; C. and Szegö, *C. A.* **22**, 2722; C. and Ricci, *loc. cit.*; Pfeiffer and Richarz, *C. A.* **22**, 1291; Tarugi, *C. A.* **22**, 1293; Zwikker, *C. A.* **24**, 4259). In some cases the acid salts which are formed from primary nitroso complexes by weak acids or by great diln. of their aq. solns. are relatively stable. They probably contain the oxime group, thus: $(NC)_5Fe...N{:}C<$, but in some salts at least the NO group may be present: $(NC)_5Fe...NC<$ (with O). In this connection the facts are significant that the complexes obtained from arylnitroso derivs. of the type: $[(NC)_5Fe...NPh]Na_3$, are comparable in all their properties to nitroso- and isonitrosopentacyanides (cf. *C. A.* **20**, 1769; **24**, 4231), and that the great stability of $K_3[C_8H_7ON_2Fe(CN)_5]$ is comparable only with that of derivs. of arylnitroso compds., which it resembles insofar as it contains the NO united to the aromatic heterocyclic nucleus. The expts. described in the present paper confirm the structures already suggested. In the reaction of nitroprussiates with $EtNO_2$, $NCCH_2CO_2Et$, $PhCH_2CN$, etc., it is probable that the salts initially formed, which are intensely colored, isomerize with loss of the characteristic chromophore group: $(NC)_5FeN{:}C=$ (with O), which passes to $(NC)_5Fe.O.N{:}C=$ (with O), which in turn undergoes cleavage, with loss of the oxime anion. With $PhCH_2CN$, the transformation would be: $[(NC)_5FeN{:}C(CN)Ph]Na_4$ (red) ⟶ $[(NC)_5Fe.O.N{:}C(CN)Ph]Na_4$ (yellow) (with O). C. C. Davis

The color reactions of octacyanomolybdates. G. A. Barbieri. *Atti accad. Lincei* **12**, 148–53(1930).—There are 2 series of compds., $K_4Mo(CN)_8.2H_2O$ and $K_3Mo(CN)_8$, in which Mo has a valence of IV and V, respectively, which are analogous to ferro- and ferricyanides. To bring out this similarity further their reactions with Fe salts have been studied. $Mo(CN)_8^{IV}$ with ferric ions in acid soln. gives a deep blue

color, while $Mo(CN)_8^{III}$ does not. However, the blue is less stable, as no ppt. forms, the colored material being present in colloidal form. Addn. of Cu or Ag salts ppts. the corresponding salt. Similarly, ferrous salts with $Mo(CN)_8^{III}$ give blue coloration (*Turnbull blue*). Uranyl acetate behaves in the same way, giving a red-brown color with the IV-ion, but no color with the III-ion. The Ag salt of IV is yellow, while that of III is red-brown, corresponding to the ferro- and ferri-silver salts. A. W. C.

Notes on qualitative microchemical analysis. J. MIKA. *Bányás. Kohás. Lapok* 63, 89–97(1930).—Present qual. methods are described. S. S. DE FINÁLY

Importance of microanalysis. D. KISS. *Technika* **10,** 146–7(1929).—The development of microanalysis and a summary of its advantages over macroanalysis are given. S. S. DE FINÁLY

Microanalysis with an ordinary balance. I. Determination of nitrogen by micro-Dumas method. WM. J. SASCHEK. *Ind. Eng. Chem., Anal. Ed.* **3,** 198–9(1931).—A comparatively large sample of substance (0.1 g) is ground up with a large amt. of finely pptd. CuO and an aliquot portion of the mixt. (about 0.2 g.) weighed on an ordinary analytical balance for analysis. The error in sampling in practice is less than 0.01% as calcd. by the Baule and Benedetti-Pichler formula. When the mixt. is weighed with an accuracy of 0.1 mg. on an ordinary balance, the substance under analysis has been weighed to 0.001 mg., which is the accuracy of the microbalance. N detns. were made of *o*-toluamide, acetanilide, azobenzene and benzamide by the Pregl-Dumas method with satisfying accuracy. L. T. FAIRHALL

Microacidimetric studies. I. J. MIKA. *Mikrochemie* **3,** 143–64(1931).—A theoretical discussion of the errors involved in microacidimetric work. The proper quantities of methyl red, bromothymol blue, phenol red, phenolphthalein, thymolphthalein and alizarin red for microchem. work are worked out. W. T. H.

Colorimetric investigations of indicators in presence of neutral salts. N. V. SIDGWICK, W. J. WORBOYS AND L. A. WOODWARD. *Proc. Roy. Soc.* (London) **129A,** 537–49(1930).—The change of color exhibited by a definite concn. of an indicator in a soln. of given p_H on the addn. of a neutral salt is investigated by a colorimetric method. An optical wedge is employed in conjunction with a Lindemann electrometer and a Rb photoelec. cell, the light absorption being measured by means of the wedge shift. The photoelec. effect enters into the method only as a null-point observation. The Tizard relation $K = [H](C_1-C)/(C-1)$ is used, where K is the apparent dissocn. const. of the indicator acid, C the color of a slightly alk. soln. of methyl orange at a given concn. and C_1 the relative color, which is the ratio of the color of any other soln. to the unit color. A correction is made for the part of the H ions combined with the indicator anions to form undissocd. indicator acid. Detns. of K are made in the absence of neutral salts with varying concns. of HCl, and a method is described for studying the possibilities that the neutral salt may alter the absorption bands of the colored forms of the indicator, and that it may affect the chem. equil. between these forms. The first possibility is studied independently of the second by dealing with solns. in which the indi-

cator is completely in the yellow or the red forms. Measurements are also made of the dissocn. const. of methyl orange in the presence of varying concns. of several salts (NaCl, NaBr, NaO_3Cl, $NaNO_3$, KCl and KBr), the concn. of the indicator being $N/40{,}000$. For NaCl, K rises to a max. between 0.05 N and 0.1 N and afterward falls. A series of measurements was also carried out with a const. quantity of AcOH-NH_4OH buffer, instead of HCl, at an indicator concn. of $N/53{,}000$, and the results were of the same type for all salts; the value of $[H^+_{free}]$ rises with increase of salt concn., passing through a max. at about 0.5 N. The theoretical significance of these results is discussed.
A. L. Henne

Determinations by Wood light. A. G. Nasini and P. De Cori. *Atti III congresso naz. chim. pura applicata* **1930**, 668–78.—The use of eosin, coumarin, umbelliferone, quinine, naphtholsulfonic acids, fluorescein, acridine, dichlorofluorescein and β-methylumbelliferone as fluorescent indicators for dark solns. is reviewed. The p_H of the soln. affects the intensity of the light emitted. Detns. were made on black liquor, sulfuretted oils, wines, beers, acid $FeSO_4$ solns. and com. indigo carmine, certain advantages as well as difficulties in the use of fluorescent indicators being shown.
E. M. Symmes

Volumetric determination of selenium. B. Ormont. *Z. anal. Chem.* **83**, 338–9 (1931).—Benesch (*C. A.* **23**, 790) proposed a method for detg. Se based upon titrating a Na_2S soln. with KCN. It is pointed out that Se forms the compd. $Na_2SSe_2.5H_2O$ when it dissolves in Na_2S, instead of a colloidal soln. of Se as B. assumed. It seem probable that difficulties will be encountered in practice in attempting to det. Se by this method. W. T. H.

The microchemical determination of strontium. L. de Zombory. *Technika* 10, 147–9(1929).—The Sr (4–5 mg.) is pptd. as $SrCO_3$ and weighed after drying at 150°; or the ppt. can be treated with H_2SO_4 and weighed as $SrSO_4$. S. S. de Finály

Separation of iron-titanium-aluminum in tartrate solution. Erich Schwarz von Bergkampf. *Z. anal. Chem.* **83**, 345–50(1931).—A satisfactory sepn. of Fe, Al and Ti (corresponding to 0.084 g. Fe_2O_3, 0.018 g. TiO_2 and 0.07 g. Al_2O_3) was accomplished by first reducing the Fe^{+++} with H_2S in acid soln., making slightly ammoniacal and pptg. FeS with H_2S, making acid with H_2SO_4 and pptg. Ti with cupferron, and finally pptg. Al with oxine acetate in ammoniacal soln. The presence of V caused trouble.
W. T. H.

Determination and separation of lead and bismuth by the volumetric filtration method. Hans Th. Bucherer and F. W. Meier. *Z. anal. Chem.* **83**, 352–61(1931). B. and M. (*C. A.* **25**, 47) have shown the advantages of carrying out quant. pptns. with measurement of the vol. of reagent required to effect complete pptn. as detd by filtering the soln. and testing with more reagent and also with a soln. contg. the ion to be pptd. For detg. Pb, pptn. as $PbSO_4$, as $Pb_3(PO_4)_2$, as $PbCrO_4$ and as PbSeO, was tested, and the last two methods proved suitable for this kind of an analysis. For pptn. of Bi, a 0.015–0.02 M soln. of H_2SeO_3 is suitable. The Bi selenite is formed in 0.05–0.08 N HNO_3 soln., but HNO_3 prevents the pptn. of the corresponding Pb salt. For the detn. of Bi and Pb, therefore, make the soln. 0.05–0.08 N in HNO_3 (0.15 g. Bi or less) and the vol. of soln. about 100 cc. Heat to 70° and add the H_2SeO_3 soln. with shaking. Toward the end of the reaction, heat to boiling. After the detn. of the Bi, add an excess of NaOAc, heat to 80–90° and ppt. the Pb (0.1 g. or less) with the same H_2SeO_3 soln. or with $K_2Cr_2O_7$ soln. The results obtained in 8 analyses all agreed within 0.23 mg. (1.5% of the Pb content). W. T. H.

Separation of magnesium from potassium and sodium in the analysis for cations. G. Kalikinskii. *J. Russ. Phys.-Chem. Soc.* **62**, 1355–6(1930).—After the pptn. and filtration of $MgNH_4PO_4$, the excess PO_4^{---} is removed by adding $CaCO_3$, and the filtrate from the $Ca_3(PO_4)_2$ ppt. is divided into 2 portions and sep. tests made for Na^+ and K^+. S. L. Madorsky

Microdetermination of calcium and magnesium in the presence of each other. K. L. Malyarov. *Mikrochemie* **3**, 132–5(1931).—If not over 10 mg. of CaO or MgO (as carbonate, oxide or hydroxide) and only very little, if any, alkali carbonate is present, a satisfactory sepn. and detn. can be accomplished by taking advantage of the fact that CaO is quite sol. in water and MgO is not appreciably sol. Ignite the sample for some time, preferably over the blast lamp, cool in a desiccator over soda lime or KOH and then dissolve the CaO by means of 60–80 cc. of hot water free from CO_2. Filter and titrate the filtrate with 0.05–0.02 N HCl with methyl orange as indicator. Dissolve the residual MgO in a measured vol. of the HCl and titrate the excess acid with NaOH. W. T. H.

Determination of calcium and magnesium by titrating in the same solution. K. L.

MALYAROV. *J. Russ. Phys.-Chem. Soc.* **62**, 1529–31(1930).—Ca is pptd. by means of oxalic acid, and then, without filtration, Mg is pptd. as hydroxide from the same soln. by means of KOH. The two can then be detd. microanalytically, without sepn., in the following way: Mg is detd. by titrating with H_2SO_4, and Ca is detd. by titrating with $KMnO_4$. The soln., however, must be free from NH_4 salts, and the amt. of MgO must not exceed 0.01 g. S. L. MADORSKY

Detection of gold, palladium and silver with dimethylaminobenzylidenerhodanine. F. FEIGL, P. KRUMHOLZ AND E. RAJMANN. *Mikrochemie* **3**, 165–73(1931).—*p*-Dimethylaminobenzylidenerhodanine, $S.CS.NH.CO.C:CHC_6H_4NMe_2$, can be used to advantage for the detection of Au, Pd and Ag. To detect Ag in the presence of Au, Pt, Pd and Hg, take a drop of the soln. on a spot plate, mix it with a drop of 10% KCN soln., add 1 drop of the reagent dissolved in alc. and make acid with a few drops of HNO_3; a violet ring forms if Ag is present. Cu must be absent, as it also gives a color reaction with the reagent. 0.001 mg. of Ag can be detected in the presence of 1000 times as much Hg, 4000 times as much Au and 300 times as much Pd. Au, like Ag, gives a colored ppt. with the reagent. The reddish violet ppt. can be used as a test in a test tube or on the spot plate. After adding the reagent, its excess can be removed by shaking with ether, and a red skin will form at the layer between the 2 solns. Palladous salts give a violet ppt. Of the other Pt metals, Pt and Ir also give tests with the reagent, but not so readily; so it is possible to test for Pd in the presence of other Pt metals. Pd can also be detected in the presence of Ag if the latter is first converted into $[AgBr_2]^-$. If Au is present, it can be reduced to metal by treatment with alkali nitrite in a soln. kept neutral by the addn. of an excess of $CaCO_3$. W. T. H.

Determining molybdenum in steel. H. C. WEIRICK AND C. H. MCCOLLAM. *Heat Treating and Forging* **16**, 1145–6, 1155(1930).—In the detn. of Mo by the $PbMoO_4$ method 2 sources of error may appear: (1) the interference of elements other than Mo; (2) errors found in the method itself. If Al or V is indicated by sep. analysis, either the sulfide pptn. or the colorimetric method (Maag and McC., *C. A.* **19**, 1675) should be used. In carrying out the procedure frequent blanks must be made on the reagents to check their purity; the Pb and the NH_4 acetate solns. should be reasonably fresh; the NaOH should be of high purity; and the correct amt. of HCl should be added. J. BALOZIAN

Detection of fluorine in plants and soils. PAUL RECKENDORFER. *Mikrochemie* **3**, 126–31(1931).—The method depends upon the combustion in a calorimetric bomb with O_2 at a pressure of 25 atm. About 2 g. of the sample was compressed to a small pill, and this pill was covered with a cotton wick. A little 20% KOH soln. was also placed in the bomb. The combustion was effected as in the detn. of the heating value of coal. After the combustion the ash and the KOH soln. were examd. separately for F, the test depending upon volatilization as SiF_4 by treatment with SiO_2 and H_2SO_4 and carrying out the molybdate-benzidine test for the sol. Si compd. By means of soil and plant tests it was shown in one case that the F content of a plant was due to fumes and not to absorption from the soil. W. T. H.

Rapid determination of small quantities of boric acid by the intensity of the flame coloration. WOLDEMAR STAHL. *Z. anal. Chem.* **83**, 340–4(1931); *Acta Univ. Latvensis Kim. Fakultat Serija* **1**, 401–7 (in Lettish), 407 (in German).—With the aid of turmeric paper and standard solns., Bertrand and Agulhon (*C. A.* **8**, 2005) detd. 0.0005 to 0.1 mg. of B. By means of the green flame test with Me_3BO_3 it is easy to det. 0.3 mg. of B_2O_3 or more with an accuracy of 0–15%. For this purpose it is necessary to have a colorimetric scale, produced with standard solns. of known B content, 3 Bunsen burners of the same size, and an app. suitable for introducing equal vols. of air through the soln. being tested and through 2 standard solns. The best mixt. consists of 100 vols. of MeOH and 20 vols. of H_2SO_4. Directions are given in detail and the results of many tests are included. W. T. H.

Titration of sulfate in the presence of ferric ions. L. DE ZOMBORY. *Technika* **10**, 192 3(1929).—If 1–3 cc. of dil. H_3PO_4 is added to a soln. contg. SO^{--} and Fe^{+++}, then an excess of 0.5 *N* $BaCl_2$ soln. should be added. The excess $BaCl_2$ can be detd. by titration with 0.2 *N* alkali or NH_4 sulfate soln. in the presence of 5–10 drops of 0.25% Na rhodizonate soln. as an indicator. The red color changes to a greenish white at the end point. S. S. DE FINÁLY

Method for the estimation of iron in biological material. ROBERT HILL. *Proc. Roy. Soc.* (London) **B107**, 205–14(1930).—Addn. of $\alpha\alpha'$-dipyridyl to a soln. of a ferrous salt between p_H 3.5 and 8.5 yields an intense-red complex ferrous ion. The color is not influenced by the presence of other metals unless they are present in great excess over the Fe.

Their presence may be overcome by use of sufficient excess of the reagent to insure complete transformation of the Fe into its dipyridyl complex. Fe^{+++}, except in high concn., gives no color and does not interfere with the reaction for Fe^{++}. Both Fe^{++} and Fe^{+++} may be detd. by addn. of dipyridyl and measurement of the intensity of the pink color both prior to and after reduction. The best reducing agent for this purpose is $Na_2S_2O_4$ prepd. as follows: To an almost satd. soln. of $Na_2S_2O_4$ at 40° add sufficient $\alpha\alpha'$ dipyridyl to produce the max. red color (traces of Fe^{++}), filter rapidly on a Buchner funnel, and ppt. $Na_2S_2O_4$ from the filtrate with alc. Let stand 20 min., collect the ppt. on a filter, wash with 70% alc. until colorless, then with 97% alc. Boil with 97% alc. for 10 min., filter immediately and transfer the salt at once to a vacuum desiccator contg H_2SO_4. Hydrazine hydrate may also be used as a reducing agent at a temp. of 40° $\alpha\alpha'$-Dipyridyl does not react with reduced hematin or pyridine-hemochromogen and does not remove Fe from hematin; it inhibits the catalytic reactions of Fe ions. Iodides, tungstates, alkaloidal reagents and $Fe(CNS)_3$ + HCl tend to interfere with the development of the red color, usually by causing formation of a ppt. Permanent standards are prepd. by sealing 5 cc. of a standard soln. in a tube 1.3 cm. in diam. and 8 cm. long The standard solns. are prepd. from 2 stock solns., 0.01 *M* ferrous ammonium sulfate, and 0.03 *M* $\alpha\alpha'$-dipyridyl-HCl; these solns. are equiv. from the viewpoint of the colored complex ion. The most concd. standard is 0.0001 *M* ferrous dipyridyl, contg. twice the theoretical amt. of the dipyridyl group; it is prepd. from the 2 stock solns., acetate buffer and a trace of $Na_2S_2O_4$. From this standard are prepd. 23 addn. standards, contg. from 0.0051 to 0.00056 mg. Fe^{++} per cc., acetate buffer soln. being used as the diluent. SO_2 is passed into the Standards prior to sealing in order to insure their permanence. The p_H of unknown solns. is brought within the proper limits by addn. of a soln. of Fe-free AcONa contg. AcOH. The ferrous dipyridyl may be adsorbed by proteins in neutral, slightly alk. or even slightly acid solns.; this usually may be prevented by use of AcONa plus SO_2, or of 30% alc. These procedures may be used for the detn. of Fe in biol. material without previous incineration. Baker's yeast contained 0.0016% non-hematin Fe^{+++}, hen egg yolk 0.0085% Fe^{+++} probably as colloidal $Fe(OH)_3$. At p_H 7.3, low concns. of $\alpha\alpha'$-dipyridyl inhibit the catalysis of the oxidation of cysteine by Fe, but have no influence on the action of Cu on this reaction.

JOSEPH S. HEPBURN

Determination of gold in animal substances. S. TUKATS AND M. LEINZINGER *Magyar Gyógyszerésztud. Társaság Értesitöje* 6, 43–54(1930).—Treat the sample with concd. HNO_3, evap. and heat the residue in an elec. oven to about 300°. To the ash add 3 cc. HCl and 30 cc. of $CaOCl_2$ soln. and evap. to dryness. Add 1–2 drops of 25% HNO_3, 2 cc. of fresh Cl_2-water and 5 cc. of water. Add 1–2 drops H_3PO_4 and boil 10–15 min. to remove Cl. The soln. is now ready for an electrolytic, gravimetric or iodometric detn.

S. S. DE FINÁLY

The Nessler reagent and its action on reducing sugars. LIVIO PAVOLINI. *Chim. ind. agr. biol.* 7, 39–40(1931).—Instead of Fehling soln., which is blue and does not permit a good observation of the color changes, P. proposes Nessler soln. (alk. soln. of K_2HgI_4) for the detection of sugars: 5 cc. of cold soln. contg. 0.1–0.2 g. sugar are treated with 0.5 cc. of reagent and shaken: a yellow or green-yellow ppt. is obtained with glucose, lactose, fructose and dextrin. Sucrose does not give the test. G. A. B

Microdetermination of glucosides in plant materials, with emphasis on the difficulties. ANNELIESE NIETHAMMER. *Mikrochemie* 3, 136–42(1931).—Rosenthaler (*C. A.* 24, 3531) has indicated the advantages of sublimation tests for the identification of glucosides in plant materials. His work is confirmed by studies on the bark of the wild horse-chestnut contg. esculin, seeds of the yellow wattle and of cow wheat contg rhinanthin, bark and leaves of the elder contg. syringin, leaves of the common leek contg. saponarin, digitalis plants contg. digitonin and bark of the *Salix caprea* contg salicin. The glucosides, to be sure, undergo slight decompn. during the sublimation, but the sublimate usually yields crystals which can be identified, particularly after treatment with Br-KBr soln.

W. T. H

The determination of arsenic in arsenobenzenes. UGO CAZZANI. *Giorn. farm. chim.* 79, 62–4, 67–70, 73–4, 77, 107–14, 117–8, 163–6, 169–72, 175–8, 181–3, 186–7 (1930); cf. *C. A.* 20, 263.—A complete review is given of the various methods employed in the detn. of As in arsenobenzenes. The methods are described in detail and their merits and defects are discussed. Lehmann's method (with slight modifications), De Myttenaere's method, and the bromometric method of Kircher and Ruppert are considered to be the best methods; analytical evidence is given in support of this view. The following modification of Lehmann's method is suggested. Mix 0.2 g. of arsenobenzene with 1 g. of finely powd. $KMnO_4$; add 5 cc. of 30% H_2SO_4 slowly, with gentle

agitation. Allow to stand 10 min., shaking occasionally. Then add 10 cc. of concd. H_2SO_4 and some H_2O_2 soln. Add 5 cc. of H_2O_2 in excess after the liquid has become limpid and colorless. Dil. with 25 cc. of H_2O and gently boil the liquid until white heavy fumes appear. After cooling add 50 cc. H_2O, cool again, add 2.5 g. of powd. KI, cover the flask with a watch glass and shake until the KI is dissolved. Allow to stand in the dark for 1 hr. and then titrate with 0.1 *N* $Na_2S_2O_3$ without starch. Run a blank in the same way. C. prefers the following procedure. To 0.20 g. of substance add 10 cc. of H_2O_2 soln. and 10 cc. of concd. H_2SO_4. Heat gently on the sand bath until more gas is evolved. Remove from the sand bath, add 5 cc. more of H_2O_2 soln. and heat gently until no more gas is evolved; then heat strongly for 10–15 min. Dil. the resulting colorless liquid with 50 cc. H_2O; add dropwise 1% $KMnO_4$ until a rose color persists. Decolorize with oxalic acid soln., cool, add 2.50 g. of powd. KI and shake the soln. in a covered flask until the KI is dissolved. After 30 min. in the dark titrate with 0.1 *N* $Na_2S_2O_3$ soln. without addn. of starch. Then add 75 cc. of satd. Na_2CO_3 soln. and about 10 g. of $NaHCO_3$ and titrate with 0.1 *N* I until a light yellow color persists. Run a blank test in the same manner. Comparative results are shown with various procedure and 2 pages of references are given. G. SCHWOCH

Critical study of the method proposed by G. Florence for finding alkaloids in viscera. N. J. JOANID. *Bull. soc. chim. biol.* **12**, 1001–13(1930); cf. *C. A.* **21**, 3905.—Recovery of strychnine, morphine and cocaine from fresh and putrefied beef was much lower when the method proposed by F. was used, instead of the method of Kohn-Abrest (modification of Stas-Otto method). Recovery from the organs of a dog poisoned with strychnine was only 0.25 that recovered by the older method. C. G. KING

Detection of semen in legal cases. J. PELTZER. *Chem.-Ztg* 55, No. 7, 70(1931).—Microscopic examn. of an aq. or H_2O_2 suspension may disclose characteristic elements or spermatozoa. The suspected spots or flecks are moistened with H_2O_2. If semen is present, much foaming occurs. Microscopic mounts may be stained with 2% aq. soln. of eosin. If the mount is pos., long, lance-like characteristic crystals (of Florence) appear. The addn. of I-KI soln. to the mount in very small amt. colors the crystals chocolate-brown at first; gradually the crystals disappear but are recrystd. by the addn. of a little more of the I soln. The presence of spermatozoa or of the Florence crystals is pos. evidence of the presence of semen. C. R. FELLERS

Titration of ethylenic nitriles. G. HEIM. *Bull. soc. chim. Belg.* **39**, 458–61(1930).—Ethylenic nitriles, with a double bond in the α–β position, add Br much more slowly than nitriles with a β–γ double bond. If the following conditions are respected, a mixt. of both forms can be titrated by bromination, because for practical purposes the α–β forms are not affected. Dissolve the nitriles in enough $CHCl_3$ to obtain 1/40 mol. in 100 cc. of soln. The brominating soln. is a 0.1 *N* Br aq. soln. contg. 100 g. KBr/l. For titration, add twice the quantity of Br soln. needed for the amt. of nitrile, shake vigorously for 10 seconds to emulsify, add a 10% KI soln. and titrate the I liberated. A. L. HENNE

Three new reactions of alanine. JUAN A. SÁNCHEZ *Semana méd.* (Buenos Aires) **1931**, I, 651–3.—(1) Heat 0.01 g. alanine with 20 drops of 1% $KMnO_4$ soln. to 100° for 1 min., cool, add 0.05 g. oxalic acid and then to the colorless liquid 2 cc. EtOH, 0.02 to 0.03 g. *o*-nitrobenzaldehyde and 10 drops of 30% NaOH. Shake with $CHCl_3$; the $CHCl_3$ takes a blue color. The reaction is explained as being due to the formation of indigo. (2) Heat alanine with NaOCl for some seconds, add 2 drops of 30% NaOH and by drops a soln. of I in KI. A ppt. of CHI_3 is formed. The intermediate formation of AcH is supposed. (3) Heat dry alanine in a closed tube and dissolve the condensed vapors in dil. HCl. The soln., which contains $EtNH_2$, gives with the reagent of Bouchardat a reddish brown ppt., with Dragendorff's reagent a red one and with S.'s molybdic reagent a white ppt. A. E. MEYER

Determination of benzene in alcoholic solutions. GY. GRÓH AND E. FALTIN. *Magyar Chem. Folyóirat* **36**, 156–9(1930).—Small quantities of benzene may be detd. by means of the characteristic absorption in the ultra-violet spectrum. Extinction coeffs. of alc. benzene solns. were detd. by a Hilger's spectrograph in layers of various thickness, and it was found that the law of *Beer-Labert* holds. Sensitivity was found to be 0.01 g. per l. S. S. DE FINÁLY

Color tests for some saturated and unsaturated carboxylic acids. L. EKKERT. *Magyar Gyógyszerészetud. Társaság Értesitője* **7**, 121–4(1931).—Color tests with different aldehydes were tried. Satd. monocarboxylic acids with few C atoms do not give tests with aldehydes in alc.-H_2SO_4 solns. Acids with more C atoms, *e. g.*, palmitic and stearic acids and unsatd. acids, *e. g.*, oleinic and ricinoleic acids, show, on the contrary, striking color reactions. S. S. DE FINÁLY

Examination of a new reaction of acetic acid. J. ERDÖS. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 332–6(1930).—The color test with La nitrate described by Krüger and Tschirch (*C. A.* **23**, 5129) was studied. The minimum quantity of AcOH giving a blue color was found to be 0.1 mg. as stated by K. and T. The test fails if over 1.5 times as much lactic acid is present, no test was given in 1% soln. by several mono-, tri- and amido-substituted acetic acids, acetonitrile, aniline acetate, Et acetate, or iso butyl acetate. NaOAc gave the blue color. The following conclusions are drawn (1) Substitution in the Me radical of acetic acid, (2) esterification of carboxyl by org radicals and (3) substitution of a carboxyl group prevent the reaction, but (4) inorg salts of AcOH give a positive test. S. S. DE FINÁLY

Allen's Commercial Organic Analysis. 5th ed., revised. **Vol. VIII.** Glucosides, Non-Glucosidal Bitter Principles, Enzymes, Putrefaction Bases, Animal Bases, Animal Acids, Cyanogen and the Cyanogen Halides, Proteins and the Digestion Products of the Proteins. Edited by S. S. SADTLER, E. C. LATHROP AND C. A. MITCHELL. Philadelphia: P. Blakiston's Son & Co. 733 pp. $7.50. Cf. *C. A.* **22**, 1303.

8- MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Röntgenographic examination of remelted algodonite and whitneyite. Supplement. FELIX MACHATSCHKI. *Centr. Mineral. Geol.* **1929A**, 371–3; *Chem. Zentr.* 1930, I, 957; cf. *C. A.* **25**, 1459.—The expts. of Borgström (*C. A.* **12**, 2507), on the remelting of algodonite and whitneyite were checked by x-ray study. The results obtained confirm the view of B. that different products, namely Cu_6As and Cu, are formed. G. SCHWOCH

Two minerals from the Belgian Congo. I. A non-pyro-electric tourmaline. II A colorless chrysoberyl. J. MELON. *Bull. sci. acad. roy. Belg.* [5], **16**, 996–1000 (1930).—The tourmaline occurs in fine needles, very pleochroic, d. 3.0, n about 1.630 The chrysoberyl occurs in hexagonal prisms. Measurements are given. R. S. DEAN

Chemical and crystallographic investigations on lithidionite from Vesuvius. GUIDO ÇAROBBI. *Rend. accad. sci. Napoli* [3], **36**, 21–31(1930); cf. *C. A.* **25**, 1462.—Lithidionite occurs both in vitreous and cryst. forms. The cryst. phase is richer in Cu, and samples contg. 13.29% CuO had sp. gr. 2.737–2.742; the vitreous phase, contg. 2 to 3% CuO, had 2.483–2.373. Analyses of 3 samples ((*a*) vitreous, (*b*) vitreous plus cryst., and (*c* cryst.) are given. They establish its formula to be essentially $(Cu, Na_2, K_2)Si_3O_7$, with CaO, MgO, Fe_2O_3 and PbO present as minor constituents. The lithidionite probably contained $Fe_2Si_3O_8$ in solid soln. It was microscopically heterogeneous, and small quantities of wollastonite, and possibly of rivaite, were sepd. from it. It is monoclinic, optically —; $2V = 124°$; the n_D^5 are: $n_p = 1.548$ and $n_m = 1.574$. Selected crystals contg 13.29% CuO melted at about 780° to a blue glass which did not devitrify on cooling. An analysis of a sample of *neocianite* agrees well with that of lithidionite, establishing their identity. Arguments are advanced in support of the existence of *rivaite* as a definite mineral species. R. H. LOMBARD

Genesis of Japanese acid clay. K. KOBAYASHI AND K. YAMAMOTO. *Chem. News* **142**, 116(1931); cf. *C. A.* **24**, 2352–3.—The acid clay is formed exclusively along an intrusion of liparite through pre-tertiary strata. Chalcedony, opal, pumice, primary kaolin and fine crystals of pyrite occur as impurities. Its formation is attributed to the decompn. of interposed Na feldspar and Na silicate. W. L. HILL

Quinquennial review of the mineral production of India for the years 1924 to 1928.

Records Geol. Survey India **64** (1930). **Jadeite.** J. COGGIN BROWN. 146–54.—The jadeite occurs as large lenses (5–7 ft. thick) in albite intruded into partially serpentinized peridotites. Alluvial jadeite is also produced. **Mica.** CYRIL S. FOX. 233–54.—Most of the Indian mica comes from pegmatites traversing mica schists. The pegmatites usually have a quartz core with marginal feldspar. Between these 2 are the largest mica books. Marketable mica is also found along the contact between dike and schist. The mica-bearing pegmatites are recrystallized products of the schists. Less than 1% of the quarried rock is marketable mica. Other associated minerals are biotite, tourmaline, garnet, apatite, beryl and rarely samarskite, pitchblende and monazite. **Ruby, sapphire and spinel.** J. COGGIN BROWN. 273–6.—The following gems are produced in Burma: quartz (amethyst, etc.), apatite, beryl (aquamarine), chrysoberyl, epidote, garnet, iolite, lapis lazuli, feldspar (moonstone), olivine, phenakite, tourmaline (rubellite), topaz, zircon. Most of the precious stones, and all the rubies and spinels, have been derived from bands of cryst. limestone in Archean gneisses. **Zircon.** W. A. K. CHRISTIE. 312–3.—Zircon occurs (6%) in the Travancore sands, worked chiefly for ilmenite. **Bauxite.** C. S. FOX. 328–43.—India contains large deposits of bauxite, largely unexploited. Uses are extensively discussed. **Steatite.** E. L. G. CLEGG. 437–40.—Steatite is one of the most widely distributed minerals in India. A. H. E.

The Tadzhikistan phosphate region. B. M. ZDORIK. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 504–16(1930).—Z. gives the geology of the region, petrography and mineralogical components of the rocks and of the phosphate deposits, their extent and approx. analyses. J. S. JOFFE

Hydrargillite and sulfurous bauxite in Istria. T. KORMOS. *Bányás. Kohás. Lapok* **63**, 269–77(1930).—Bauxites of Santa Domenica and Portole show postvulcanic influences, *e. g.*, a bluish gray bauxite with 10% S. Hydrargillites of the same region are probably of secondary origin formed independently of the bauxites, since they contain no Ti nor S, but have $H_2O > 30\%$. Several bauxite analyses are published. S. S. DE FINÁLY

Coal formation, mountain formation and bauxite formation in Hungary. E. VADÁSZ. *Bányás. Kohás. Lapok* **63**, 213–20(1930).—The largest coal occurrences of Hungary were formed in post-orogenic sinking periods. Coal formation generally took place during the change of earth surface caused by the orogeny; the formation of bauxites, on the contrary, is the dry-land formation product of an ended orogeny. S. S. DE FINÁLY

The Kuréjka graphite occurrence of the Tunguzka coal basin, Siberia. A. PÉCZELI. *Bányás. Kohás. Lapok* **63**, 242–52, 277–81(1930).—A coal basin covering about 900,000 sq. km. consists of 2 types of rock deposits. Coal of younger formation (Angara-type) is weakly metamorphic, contg. rather considerable ash. Coal of older formation (Jenissei-type) is strongly metamorphic. The 14-m. amorphous graphite deposit of Kuréjka lies on a 1.5 m. lime layer. The proved coal content of the basins is estd. at 1,200,000 metric tons. S. S. DE FINÁLY

A new physicochemical explanation of the formation of humus, peat and coal. The significance of biological factors in these processes. J. ZOLCINSKI. *Wiss. Arch. Landw.*, Abt. A, *Pflanze* **4**, 196–228(1930).—Decompn. of org. material of both plant and animal origin follows the same basic laws as are observed for the decompn. of rocks and minerals, in which simpler, more stable compds. are formed. Seventy references are given. W. GORDON ROSE

Comparison of the behavior to thermic action of rock from Ragusa and from Abruzzo. M. G. LEVI AND C. COLLINA. *Atti III congresso naz. chim. pura applicata* **1930**, 740–52.—The rocks studied were asphaltic calcites. They were subjected to fractional distn. to sep. liquid, solid and gas. A plant design is shown to sep. these substances commercially, a part of the rock being used for fuel. The residue can be used for CaO *manuf.* E. M. SYMMES

Sapphires. J. W. HOWARD. *J. Chem. Education* **8**, 613–24(1931).—The sources, mining, sorting, grading and properties of natural sapphires are described. Details of the prepn. of synthetic sapphires are given and the methods of distinguishing natural and synthetic sapphires discussed. E. H.

Classification of rocks. F. PAPP. *Bányás. Kohás. Lapok* **63**, 556–63(1930).—The classification of Hungarian rocks is discussed. S. S. DE FINÁLY

Astrophyllite-bearing nephelite syenite gneiss—found as a boulder in Kiihtelysvaara, eastern Finland. PENTTI ESKOLA AND TH. G. SAHLSTEIN. *Bull. comm. geol. Finlande* **1930**, No. 92, 77–88.—The mineralogical composition of the boulder was nephelite 34.27, plagioclase 27.92, K feldspar 17.15, amphibole 13.86, aegirite 0.14, astrophyllite 2.30, cataplеite-like mineral 0.90, titanite 1.01, cancrinite 0.18, apatite

0.45%. It is accordingly highly alk. and unlike any outcrops in the vicinity.
R. S. DEAN

The disintegration of rapakivi. PENTTI ESKOLA. *Bull. comm. geol. Finlande* 1930, No. 92, 96–105.—The Finnish word rapakivi means crumbly stone and is used to designate certain granites which disintegrate spontaneously. The disintegration of rapakivi seems to presuppose the coincidence of several different circumstances. Its main condition seems to be a comparatively simple texture with rather smooth boundary surfaces between the mineral grains. The consistency of the rock may have been, and in some cases certainly has been, loosened by slight disturbances in the crust. Where layers thus predisposed become exposed to air and rain water and subjected to the influence of temp. changes, there the rock will break up into grit. At the same time chem. weathering sets in, causing decompn. of the Fe-rich lepidomelane and oxidation of its Fe^{++} into rusty products. Part of the anorthite in the plagioclase, moreover, may be dissolved and some of its Al_2O_3 may remain in the insol. portion. From a rock which like the rapakivi is available in the form of loose grit the heavy minerals may be easily sepd. by means of panning. The rapakivi was thus found to contain considerable amts. of zircon and ilmenite, but no other minerals heavier than hornblende.
R. S. DEAN

Rocks of the upper Bargousin and Namama regions in Transbaikalia. PENTTI ESKOLA. *Bull. comm. geol. Finlande* 1930, No. 92, 106–40.—The following rocks occurring in the Bargousin region are described: graphite-bearing limestone, amphibolites and gneisses, quartzite, granite In the Namama region, cryst. limestone and dolomite, quartzite shale, greenschists and metamorphic andesites are described as supercrystal and quartz keratophyre; orthoclase porphyry, granite, granodiorite, hornblende gabbro and hornblendite are described as intracrustal. Cu ore also occurs in the cryst. limestone bounded on the east by quartz keratophyre and on the west by Namama diorite. The chem. nature of the igneous rocks of the Bargousin magmatic province is discussed in detail.
R. S. DEAN

The eruption of the volcano of the Kaménis (Santorini) in 1925. CONST. A. KTENAS. *Bull. volcan.* **4**, 7–49(1927); cf. *C. A.* **20**, 564; **21**, 880; **24**, 2086.—A general description is given of the eruption. Two analyses of fumarole gases and 4 of lavas are given.
H. S. WASHINGTON

Report on studies on the last eruption of the Kaménis (Santorini). CONST. A. KTENAS. *Bull. volcan.* **4**, 171–6(1927).—An addn. is made to previous papers on the eruption without new analyses.
H. S. WASHINGTON

Report on the work of the Laboratory of Petrology of the University of Athens, relating to the study of the volcanoes of the Aegean Sea. CONST. A. KTENAS. *Bull. volcan.* **4**, 182–7(1927)(map).—Brief notes are given on the petrography of some little known Greek island volcanoes The lavas are mostly dacites and andesites. H. S. W.

The basaltic volcanoes of southern Indochina. M. F. BLONDEL. *Bull. volcan.* **4**, 193–4(1927).—Very brief notes are given. No analyses are included. H. S. W.

The chemico-mineralogic characters of the Tertiary intrusive and volcanic rocks of North Africa. A. LACROIX. *Bull. volcan.* **4**, 199–204(1927).—A summary paper Although no analyses are given, the rocks are classified according to the C. I. P. W. system.
H. S. WASHINGTON

First observations on the mineralogic and chemical composition of the Mesozoic and Tertiary lavas of eastern China. A. LACROIX. *Bull. volcan.* **4**, 205–17(1927). Brief petrographical descriptions are given with 20 chem. analyses.
H. S. WASHINGTON

The lithologic constitution of the South Central Pacific. A. LACROIX *Bull. volcan.* **4**, 218–31(1927).—A general petrological description is given; no analyses are included.
H. S. WASHINGTON

Collection of chemical analyses of Russian eruptive and metamorphic rocks. A. NÉMOVA AND F. LOEWINSON-LESSING. *Mem. Com. Geol.* (Moscow), New series, No. **186**, 361(1930).—The collection numbers 1676 analyses. The text is in Russian, except that rock names are also given in French.
H. S. WASHINGTON

Unusual depositional stalactites in a lava-tunnel at Mount Albert, Auckland. J. A. BARTRUM. *New Zealand J. Sci. Tech.* **12**, 188–92(1930).—The material appears to consist of crust-like layers of small white flakes of opal intermixed with kaolin and sepd. irregularly by similar discontinuous thin layers of granular white kaolin.
H. C. PARISH

Slippings of clay territories at Budapest. A. VENDL. *Magyar Mérnök Építészegylet Közlönye* **64**, 65–72(1930).—Slippings are caused by a thin water-contg. layer within the loess covering Kiscelli clay strata.

D. J. DEMOREST, H. W. GILLETT AND RICHARD RIMBACH

Development and present state of metallurgy. F. ALTNÉDER. *Bányás. Kohás. Lapok* **62,** Supplement 3–46(1929).—A historical and descriptive treatise including a bibliography. S. S. DE FINÁLY

Origin of flotation. L. MICHEL. *Rev. financiera salitre y minas* (Santiago) **5,** 702–4(1930).—A historical review. E. I. S.

Properties of the bog iron ore from Hokkaidoh and of the brown iron ore from Chohsen as determined by thermal analysis. KATSUMI INOUE. *Tetsu-to-Hagané (J. Iron and Steel Inst. Japan)* **17,** 99–108(1931).—From thermal analysis of these ores, the heat necessary to expel the combined water was calcd. The amt. of heat required for the bog iron ore was larger than that for the brown ore at the same rate of heating, though the decompn. temp. of the former was lower than that of the latter. I. attributed this to the internal strain in the grains of the Chohsen brown ore. The sintering temp. of the brown ore of Chohsen was higher. M. KURODA

Investigation on the reduction processes of iron ore. III. BERTIL STÄLHANE AND TORE MALMBERG. *Jernkontorets Ann.* **114,** 609–722(1930).—The reduction of Kiruna magnetite in H_2 and H_2-CO mixts. has been investigated. At 950° 0.2 mm. grains were completely reduced by H_2 in 2 min.; 2.0 mm grains in 7 min. and 4.0 mm. grains in 17 min. The rate falls off with the temp. but there is a marked discontinuity at 910°, at which temp. the time required is 2.5 times that at 890°. Addn. of CO to the H_2 slows up the rate quite markedly, the rate in 100% H_2 being 7 times as great as in 100% CO. Pure CO also gives the same discontinuity as H_2 at 910°. Mixts show the same but less markedly. The temp. at which the reduction becomes exceedingly slow, 900°, corresponds to the transition point of α-Fe to γ-Fe. H. C. DUUS

Statistics on the Swedish iron industry during recent years. ARVID JOHANSSON. *Jernkontorets Ann.* **114,** 623–34(1930).—Consumption of charcoal decreased from 2.72 million cu. m. in 1924 to 1.98 million cu. m. in 1929. The production of Fe ore remained sensibly const. at 550,000 to 670,000 tons. The value of the export was 8.5% of the total value of all exports, and the value of imports 4.9% of the total. H. C. DUUS

Superroasting of zinc blende by different methods. E. PROST. *Rev. univ. mines* **72,** 234–40, 269–77(1929). E. I. S.

Free energy of some copper compounds. MERLE RANDALL, RALPH F. NIELSEN AND GEO. H. WEST. *Ind. Eng. Chem* **23,** 388–400(1931).—A review, intended primarily to aid Cu metallurgists, of the equilibria in various reactions of Cu compds. The free energies of various Cu compds. important in the metallurgy of Cu are given. References (102) to articles in the literature used in obtaining the data are given. J. B.

Sand tests in the foundry. J. HIRD. *Foundry Trade J.* **44,** 191–3, 197(1931).—Methods for making sand tests and their application to foundry control are described for both facing and core sands. Data sheets are included showing various phys. properties of many types of sands found in several different districts in England. D. S.

Investigation of furnaces used in rolling mills. L. A. RICHTER. *Stahl u. Eisen* **51,** 377–85(1931).—A review of the operating practice of the furnaces used in rolling mills in Austria. The type of furnaces, the method of operation, the heat balance, the oxidation losses, the dependence of the fuel consumption on the type of material rolled and the ratio of the hearth surface to the total furnace surface are discussed. J. A. SZILARD

Rotary-hearth furnace for heat treating. R. E. BARKER. *Heat Treating and Forging,* **16,** 1189–90(1930).—A rotating hearth mounted on ball bearings in oil and motor-driven is described. It burns producer gas, natural gas, oil or tar, is adaptable to all classes of steel and has proved ideal for "open" annealing of all types of material. J. BALOZIAN

Utilization of slag from blast furnaces in Japan. TAIZOH KURODA. *Tetsu-to-Hagané (J. Iron and Steel Inst. Japan)* **17**, 118–22(1931).—Statistics of the production of pig iron and slag in Japan are given. The main uses for slag are in the production of cement, slag ballast, brick and slag wool. The analyses of slag and its uses in 8 main blast furnace works in Japan are given. M. KURODA

The slag in the basic open-hearth steel furnace. R. BACK. *Stahl. u. Eisen* **51**, 317–24, 351–60(1931).—In 19 melt tests carried out in the basic Siemens-Martin furnace, the basicity of the slag as characterized by the $CaO:SiO_2$ ratio was followed During the melt-down period, with increasing basicity of the slag, the amt. of Fe in the form of oxides increased, while the SiO_2 content decreased. No definite relationship could be found between the Mn content of the slag and the basicity during the melt down period. Increasing amts. of Mn addns. caused increased Mn content in the slag during this period. During the boiling period, which, in the scrap-Fe process, is the time between the end of the melt-down and the addn. of the finishing flux, the Fe and Mn contents increased with the increasing basicity of the slag. Five different types of slag, classified according to the $CaO \cdot SiO_2$ ratio, were investigated: acid slag with a ratio of 1.3–1.5, medium basic 1.5–1.8, good normal 1.8–2.0, basic 2.0–2.4 and highly basic over 2.4. The above ratios refer to the compn. of the slag at the end of the boiling process. For the regeneration of Mn from the slag the acid slags, contrary to expectation, gave very good results. The best results were obtained with the medium basic slags. Even with the good normal slag the Mn had the tendency to go back from the slag into the bath. In the basic slag the tendency for the reduction of Mn was found to be very slight. The highly basic slag gave the poorest results. At very high temps the results with highly basic slag were somewhat better. The Fe content of the slag during the boiling period, as in the melt-down period, is a direct function of the basicity of the slag. The Mn content is governed by the Fe content: with increasing basicity more FeO and Fe ferrite are formed in the slag and these have an oxidizing effect on the Mn in the bath. It is emphasized that the basicity of the slag has a detg role in the transformation of Fe and Mn. The slag test is described; it gives a good indication of the compn. of the slag and is of importance in cases where the P and Si contents of the raw materials are subject to great variations J. A. SZILARD

Method of slag determination. H. KJERRMAN. *Jernkontorets Ann.* **1929**, No. 4, 181–99.—A discussion of (1) the slag of different kinds in steel, (2) its microscopical detn., (3) the relation between slag content and strength and (4) the sulfate content in Cr ball-bearing steel. E. J. S

Some modern tendencies in siderurgy and the establishment of this industry in the Argentine Republic. SVEN WASSMAN *Anales soc. cient. argentina* **111**, 65–92(1931). E. H

The preparation of the raw materials at the Röchlingen Iron and Steel Works in Völklingen (Germany). A. WAGNER. *Stahl u. Eisen* **51**, 217–25(1931).—The parts of the plant for the prepn. of the raw materials, including breaking, screening and sintering, are described and their economies discussed J. A. SZILARD

Choice of raw materials for malleable cast iron. I. II. III. J. V. MURRAY *Metallurgia* **1**, No. 3, 107–9, No. 4, 161–2, 165; **2**, No. 9, 101–2(1930). E. J. C

Statistical evaluation of pig-iron analyses. K. DAEVES *Stahl u. Eisen* **51**, 202–4 (1931).—A method is shown for the evaluation of the daily analyses of 3 blast furnaces and one mixer during 3 months. The deviation from the av. values is greater for the blast furnaces than for the mixer. Curves are given which show the relationship between the S, Mn, Si and P contents. J. A. SZILARD

Advantages of fine-grain over coarse-grain pig iron for production of high-test cast iron. R. STOTZ. *Z. ges. Giessereipraxis* **51**, No. 3, 25–8(1930); cf. *C. A.* **24**, 42.—S seeks to show that 2 pig irons with apparently the same chem. compn. do not necessarily possess the same phys. characteristics. E. I. S

The manufacture of cast-iron rolls. E. PEIPERS. *Stahl u. Eisen* **51**, 345–51 (1931).—The manufacture of loam and chilled cast rolls is described, and also the development of alloyed rolls. J. A. SZILARD

The development of the research program of the steel-making processes on a physicochemical basis. H. SCHENCK. *Stahl u. Eisen* **51**, 197–202(1931).—In the effort to reduce production costs and improve the quality of steel products, comparatively little attention was given to the basic chem. reactions involved in steel making The unsolved problems of steel making are listed and a research plan is developed which would make coöperation between steel plants, exptl. stations and scientific research institutions possible, to obtain a better knowledge of the metallurgical processes J. A. SZILARD

Refining of aluminum and its alloys by treatment with chlorine gas and nitrogen. W. KOCH. *Metallwirtschaft*, 10, 69–72, 85–8(1931).—Lab. expts. were carried out to det. the influence of impurities in Al upon the temp. of chlorination. The samples were heated in a Cl stream in combustion boats, the temp. of the beginning of volatilization was detd. and the volatile matter analyzed. The chlorination should conform with the following theoretical considerations: (1) It is a function of pressure and temp. and subject to the mass law. (2) The chlorination temp. of a pure metal must be reduced by alloying it with another constituent of a lower chlorination temp. The bigger the difference between the chlorination temp. of the base metal and of the alloying constituent, the greater will be the influence of such an addn. (3) The volatility of the chlorides formed is an essential factor in the speed of chlorination. It is increased by the presence of compds. of a lower temp. of volatilization. Impurities act proportionally to the difference between the volatility of their chlorides and those of the base metal. The expts. brought out that the temp. of volatilization of pure Al is reduced by impurities, especially Fe and Si. At the same time the volatility of $AlCl_3$ is being increased. The impurities also interfere with the formation of a protective film, Si to a greater extent than Fe. They form centers of corrosion, thereby rendering the metal less compact and increasing the surface, both of which factors interfere with the film formation and facilitate the attack. Refining tests were made on a technical scale by introducing Cl into the molten metals and finally removing it by blowing N through the melt. Various types of com. Al and of Al-Fe, Al-Si and Al-Cr alloys were thus treated. In alloys contg. 0.8, 1.6 and 1.86% Fe, the chlorination resulted in a fine and dense grain, while the original material was coarsely cryst. The plasticity and toughness of the alloys was also increased. No change in the chem. compn. of the alloys could be ascertained. An alloy contg. 3.52% Fe and 0.43% Si showed the grain-refining effect of the chlorination especially distinctly. In this case the treatment decreased the Fe by 0.37%. In an alloy contg. 11.7% Fe and 0.45% Si no refining effect of the chlorination could be found, except the removal of considerable quantities of gases. The Fe was reduced by 0.67%. In Al-Si alloys contg. 0.8, 1.3 and 2.1% Si the chlorination had a dispersing effect upon the segregations found in these alloys, which consist mainly of Al-Fe-Si compd. The *chlorination of silumin* had a slightly coarsening effect upon the metal grain, because of the chlorination and volatilization of the colloidal Na particles. An Al-Cr alloy contg. 2.8% Cr showed only a slight refinement of the Al-Cr segregation. An alloy contg. 1.9% Cr and 1.4% Fe showed a much more distinct improvement. The eutectic and the Al-Cr segregation were finely divided and the Al grain was considerably refined. Expts. made with com. grades of Al and Al scrap showed in each case that the chlorination had the effect of refining the grain and dispersing the impurities. The chlorination has a favorable effect upon the mech. properties of the treated materials. The ductility and the bending properties are improved and the hardness is increased. The main field of application of the Cl and N treatment will probably lie in the refining of Al scrap. While a selective volatilization of the impurities appears to be impossible, a no. of valuable phys. improvements are obtained, such as: removal of gases, clean grain boundaries, grain refinement and homogenization, and an increase of fluidity. The castings obtained show a dense structure, free of blow holes, and a smooth, shiny surface. Most of the mech. properties show distinct improvements.

LEOPOLD PESSEL

An investigation of core oils. CARL H. CASBERG AND CARL E. SCHUBERT. Univ. Ill. Eng. Expt. Sta., *Bull.* No. 221, 5–22(1931).—The oils investigated were those commonly used in core work, *i. e.*, the drying oils linseed, China wood and perilla, together with the semi-drying and non-drying such as soy-bean and kerosene. The object was (1) to det. any possible relation between tensile strength of the cores and the chem. and phys. properties of the oils and (2) to note the effect of moisture on tensile strength. Tests made on the oils included ash content, sp. gr., flash and fire points, sapon. and I nos. Results showed that no definite relations exist between these properties and the av. original tensile strengths of the finished cores, although the initial tensile strength was found to be proportional to both the sapon. and I nos.

H. L. OLIN

Progress in metallurgical research. C. H. DESCH. *Foundry Trade J.* 44, 105–6 (1931).—The impregnation of solid ores by C must play an important part in the reactions of the blast furnace. Ore so impregnated with C is readily reduced at a higher temp., the fine solid C in the mass being a much more powerful reducing agent at 750° than is CO. The solid C may also form a somewhat impervious layer around the ore granules and hinder the reduction. The exact conditions detg. the form that the C will take have yet to be learned. Endurance tests, rather than short-period tensile

tests, are necessary at high temps. on metals, as creep under prolonged stress bears no const. relation to the mech. properties under static conditions. An abbreviated test, described by W. H. Hatfield has been found useful as an approx. guide. That stress is found which, at the given temp, produces an elongation not exceeding 0.5% in the 1st 24 hrs., and produces no further change of length in the next 48 hrs., when measurements are made such as would detect an elongation of the order of 1 millionth in per in. per hr. The safe stress is then taken as $^2/_3$ of this limit. Both magnetic aging and strain etching are dependent upon the sepn. of nitride from solid soln. There is no direct relation between them. X-ray analysis has greatly assisted in carrying out an immense amt. of research work relating to changes which metals undergo during deformation. App. has been devised for measuring pressures developed at the rolls and at the dies and records have been kept of power consumption with different degrees of reduction. By quenching in a blast of H and by using the string galvanometer cooling curves have been taken during the short period of quenching. The evidence thus obtained indicates that martensite is a heterogeneous mixt. contg. finely divided ferrite and cementite and not a supersatd. soln. of carbide in α-iron. H. C. P.

Literature on the use of the x-ray. II. Victor S. Polansky. *Heat Treating and Forging* 16, 1011–14(1930); cf. *C. A.* 24, 5690.—A bibliography is given of the literature available in the *Carnegie Library of Pittsburgh* on x-ray examn. of ferrous metals and alloys for authors names from F to K, inclusive. The list has been brought up to May, 1930. J. Balozian

The deformation of metals under prolonged loading. I. Flow and fracture of aluminum. D. Hanson and M. A. Wheeler. *J. Inst. Metals*, Advance copy No. 554, 29 pp.(1931).—Al samples were subjected to static loads at room temps. and at 250°. The mode of deformation was detd. by microscopic examn. of the polished and unetched surface of the test specimens. Samples consisting of various sized crystals, including single crystals, were used. Conclusions: "(1) The extension under a prolonged load that will ultimately break the metal may be conveniently considered as consisting of 3 periods: (*a*) a period of primary extension, during which the rate of flow diminishes; (*b*) a period during which flow is very slow or even suspended; (*c*) a period during which the extension again continuously increases until fracture occurs (2) During the first period the flow of the metal is the result of slip within the crystals, and flow diminishes because of the hardening effect of slip. (3) The behavior during the second and third periods varies with different specimens. (4) Three types of failure have been recognized under creep conditions: (*a*) failure by intercryst. cracking; cracks form while the elongation is low, and the metal fails with little reduction of area at the fracture; (*b*) failure by the resumption of slipping within the original crystals, leading to a fracture of the normal type; (*c*) failure through the recrystn. of the metal, removing strain-hardening and permitting further flow of the softened metal; the metal pulls out to a point fracture, with a high elongation. (5) Al can fail to "creep" at room temp. (6) Al consisting of uniform aggregates of crystals fails at 250° by intercryst. cracking. (7) Al aggregates at room temp., and Al single crystal specimens at all temps., fail under creep conditions by shear along the slip planes. (8) In single crystals when flow recommences slip occurs only on some of the surfaces that had previously slipped during the primary flow. (9) The prolonged action of a suitable stress can cause disintegration of a metal either at the junctions of the grains or on the surfaces of previous slip, and failure (*i. e.*, fracture) must be regarded as having commenced when this weakening occurs. (10) Under suitable conditions, *e. g.*, in crystal aggregates with moderate rates of flow at 250°, or with very slow rates of flow in single crystals, slip is distributed over a very large no. of slip surfaces, and a polished surface of the metal may show little or no signs of slip bands. (11) No change in density is believed to occur when a crystal is distorted by moderate amts.: changes in density in crystal aggregates are thought to occur at grain boundaries. (12) The view is expressed that rupture of the crystals commences along slip planes formed at an early stage in the deformation of the metal. (13) The results are consistent with the theory of slip and rupture previously advanced by Gough, Hanson and Wright." Four references are included. J. L. Gregg

The mode of deformation of a single crystal of silver. H. J. Gough and H. L. Cox. *J. Inst. Metals*, Advance copy No. 552, 18 pp.(1931).—A single crystal of Ag was subjected to alternating torsional stresses and the surface examd. to det. the mechanism of deformation. Numerous slip bands were formed on the octahedral planes, but there was no definite evidence of twinning even when the stresses were applied until failure. The slip bands might have been narrow twins, but this appears to be improbable. No twins could be produced by compression. Because of the ease with which twinning

occurs in an aggregate of small crystals, the mechanism of deformation in a single crystal must be essentially different from that in the aggregate. J. L. GREGG

Microstructures of fifteen silver Greek coins (500-300 B. C.) and some forgeries. C. F. ELAM. *J. Inst. Metals*, Advance copy No. 550, 10 pp.(1931).—All of the genuine coins had been struck, while only one of the forgeries showed any indication of striking. Some of the coins had apparently been struck hot. Treatment differed at different mints. Analyses indicate that Cu had been intentionally added. J. L. GREGG

New uses for aluminum. L. JAKÓBY. *Bányás. Kohás. Lapok* **63**, 236–41(1930)—A review. S. S DE FINÁLY

Some properties of metallic cadmium. C. H. M. JENKINS AND G. D. PRESTON. *J. Inst. Metals*, Advance copy No. 556, 32 pp.(1931).—Hardness and tensile values of rolled Cd show that the temp. of working has a pronounced effect on these properties. In ordinary tests the worked Cd appeared to be stronger than the cast, but the conditions were reversed in the long-time ball test. Material in the cold-rolled condition was completely recrystd. In such material appreciable grain growth was found after 5 years. No evidence was found of an allotropic transformation. By x-ray examn. the parameter of the unit cell was found to be $a = 2.9724 \pm 0.0005$ Å. U., with an axial ratio of 1.8854 ± 0.0005. In cold-rolled Cd the $(\bar{1}011)$ plane tends to lie parallel to the surface, and the normals to the basal plane (0001) are inclined at about 65° to the normal to the surface of the sheet. In hot-rolled sheet another preferred orientation is found. Seventeen references are given. J. L. GREGG

Three crystalline modifications of electrolytic chromium. KUMAZO SASAKI AND SINKITI SEKITO. *Trans. Electrochem. Soc.* 59 (preprint) 7 pp.(1931).—See *C. A.* **25**, 1195. C. G. F.

The independence of the hardness and the hydrogen content of electrolytic metals. GUICHARD, CLAUSMANN, BILLON AND LANTHONY. *Compt. rend.* 192, 623–5(1931).—The exceptional hardness of electrolytic Fe, long noted, has been attributed, on the one hand, to the fine state of diffusion of the metal and, on the other, to the presence of a compd. of H and Fe having a characteristic metallographic structure. The authors have repeated the expts. of Hugues (*C. A.* 20, 572) and reached an entirely different conclusion. The results of their expts. indicate that it is necessary to exercise considerable caution before attributing the remarkable mech. properties of electrolytic metals to the presence of occluded gases. O. W. ELLIS

Notched-bar impact tests. E. HÖEG. *1st Communications New Intern. Assoc. for Testing Materials* **1930A**, 213–6.—Notched-bar impact tests of heat-treated steel contg. 0.15% C showed the effect of the superheating after heating for 1, 2 or 3 hrs. at 1100°. Examn. of plates from an exploded boiler showed the energy absorbed in fracture of notched-bar test pieces after various heat treatments and at differen ttemps. of the test bar during the impact test. E. M. SYMMES

Cyaniding and salt-bath working. J. W. URQUHART. *Heat Treating and Forging* 16, 989–93(1930).—The details involved in successful salt-bath hardening, and general heat treatment in salt baths are briefly described. J. BALOZIAN

Heat treatment of non-ferrous metals. A. H. VAUGHN. *Heat Treating and Forging* 16, 1036–8, 1041(1930).—A brief survey is given of the present practice. J. BALOZIAN

Heat treatment of aircraft engine parts. R. R. MOORE. *Fuels & Furnaces* **9**, 279–89(1931).—The importance of proper heat treatment is outlined and methods of heat-treating steel and Al alloy parts are described. The chem. compn. and phys. properties of the Al alloys are tabulated. MORRIS SCHRERO

Variations in hardness of metals and alloys resulting from cold working. GUICHARD CLAUSMANN AND BILLON. *Bull. soc. chim.* [4], **49**, 173–85(1931).—See *C. A.* **24**, 4749. G. G.

Some phases of heat treatment of cylinder and alloy irons. F. J. WALLS AND A. HARTWELL, JR. *Trans. & Bull. Am. Foundrymen's Assoc.* 2, No. 3, 865–96(1931).—Tests were run to det. the relief of stresses in cylinder irons on heating to temps. of 750° to 1150°F. The hardness of the irons as affected by air-, water- and oil-quenching was investigated. Max. relief of stresses is obtained with min. growth and change in hardness by heating to 950°F., followed by slow cooling. Similar tests were made on Cr-Mo and Cr-Ni-Mn cast irons. C. H. LORIG

Wear resistance of nitrided nitralloy. V. O. HOMERBERG AND J. P. WALSTEAD. *Metal Progress* **18**, No. 6, 68–71(1930).—A study of the wear resistance of nitrided nitralloy against itself, gray and white cast Fe, Monel metal and 3 bronzes shows com. possibilities of nitrided materials in engine or machine parts which are subject to severe wear conditions and which are difficult to lubricate. W. A. MUDGE

Tests on the resistance of cast iron to wear. R. SPAZIER. *1st Communications New Intern. Assoc. for Testing of Materials* **1930A**, 64–73(in French).—There is no standard method in use for measuring resistance to wear of cast Fe, and no basis of comparison of results obtained by various methods of testing this property. Tests were made by pressing at 25 kg. pieces of cast Fe shaped like a brake shoe 1 cm. thick and 3 cm. deep against a steel disk 4 cm. in diam. and 1 cm. thick, revolving on an axle at 188 r. p. m., tangential velocity 0.395 m. per sec. Phys. tests of the samples were made previously. It was impossible to recognize any relation between hardness, resistance to traction, resistance to flexure and resistance to shock. In general, wear was inversely proportional to hardness. After a certain period of testing, due to the grinding action of abraded material, less hard cast Fe often showed less wear than harder samples. Wear is faster at first than near the end of the test. Wear of cast Fe is proportional to that of the steel disk. Wear is greater in a continuous than in an intermittent test. Wear increases with increase in graphitic C, and decreases with increasing P content. E. M. SYMMES

Comparison of the physical properties of different sections of cast iron and of the standard arbitration test bar. M. V. HEALEY. *Proc. Am. Soc. Testing Materials* 30, Pt. 1, 206–12(1930).—A hollow box, cast in green sand with a dry sand core was made with one wall 4″ thick, one 2″ and one nominally $^1/_2$″, but actually, from the flexure test table, $^3/_4$″. Standard 1.3″-diam. arbitration bars were cast from the same metal, in dry sand. In the different sections total C ranged from 2.74 to 3.08%; combined, from 0.49 to 0.63%; Si from 1.95 to 2.19%; Mn 0.56%; P 0.37%. In flexure tests on 12″ supports, with bars 1″ wide by 4, 2, 1 and $^3/_4$″ with 1″ dimension vertical, deflection ran from 0.165 to 0.19″ on the specimens from the casting, with no marked effect of size, while the arbitration bars gave 0.12″. The modulus of rupture of the 4″-thick section was 45,000 lb. and for the thinner sections varied from 46,000 to 52,500 with no marked effect of size. Averages showed a decrease with the size of the section but individual figures for each size scattered over about the same range. The arbitration bars, however, gave 68,000. Tensile tests showed 32,000 for the arbitration bar and 23,500–30,000 for the castings with increase in strength as the section diminished. The $^1/_2$″ section was a trifle out of line, probably through insufficient feeding. Brinell tests showed 195 for the arbitration bar and 150–170 for the casting. Brinells showed fair correlation with strength. Micrographs are shown. H. W. GILLETT

Comparative tests on cast iron in Czechoslovakia. F. PISEK *1st Communications New Intern. Assoc. for Testing Materials* **1930A**, 25–34(in French). Strength tests and cutting tests are described. E. M. SYMMES

Nitrogen in technical iron. III. The separation of nitrogen and carbon from α-iron as an example of the decomposition of a doubly supersaturated solid solution. WERNER KÖSTER. *Arch. Eisenhüttenw.* **4**, 145–50(1930); cf. *C. A.* **25**, 671 and following abstr. The tempering isotherms were detd. for a no. of steels of varying N content for different quantities of dissolved C at 100° and the increase of the coercive force measured during the first rise. For any percentage of C there exists a linear relation between the total amt. of N and the coercive force. The isothermic sepn. of N from α-Fe supersatd with it at 100° is interfered with if C in solid soln. is present at the same time. The quantities of N eliminated are smaller the higher the concn. of the dissolved C, and no sepn takes place at all if a certain limit of C is exceeded. These limiting values can be plotted as a curve in the Fe–C–N system. The points along this curve indicate the amt. of N remaining in soln.; these values depend on the amt. of C in soln. and are independent of the total amt. of N. The expts. give an example of the influence exerted by a constituent in a solid supersatd. soln. upon the sepn. of another. L. P.

Nitrogen in technical iron. IV. The combined action of cold working and nitrogen separation on the magnetic properties of technical iron. WERNER KÖSTER. *Arch. Eisenhüttenw.* **4**, 289–94(1930); cf. preceding abstr.—The influence of various heat treatments on the magnetic properties of cold-worked steels (0.012% N) is investigated. The coercive force is detd. of specimens (1) which have been cold-worked (elongated 0–20%) and subsequently annealed at 100° up to 14 days, and (2) which have been treated as in 1 and then re-annealed for 1 hr. at temps. up to 700°. These expts. show that the coercive force is a result of (1) that attributable to cold working (increasing in this case with increasing elongation), and (2) that caused by N sepn. (decreasing here approxly. linearly with the elongation). The relation between the coercive force and the degree of straining is independent of the order of treatment. The change in the magnetic properties of cold-worked steel between 100° and 300° is the result of the sepn. and soln. of N. The observations in the literature are explained on the basis of the results of these expts. J. BALOZIAN

The development of quality thin sheet iron. H. KLEIN. *Stahl. u. Eisen* **51**, 189–96(1931).—A discussion is given of the increased demand for quality thin sheet iron, leading to improvements in the equipment of rolling mills, in the annealing and finishing of sheet iron. The methods of galvanizing and tinning and the properties of rust-resisting steels are also discussed. J. A. SZILARD

Progress of the knowledge regarding slag (solid nonmetallic) inclusions in iron and steel. C. BENEDICKS AND H. LÖFQUIST. *1st Communications New Intern. Assoc. for Testing of Materials* **1930A**, 345–7.—A review with bibliography of the more important progress since the author's 1927 paper (*C. A.* **23**, 75). E. J. C.

Continuous load experiments on various construction steels at high temperatures. ERNST POHL, HANS SCHOLZ AND HUBERT JURETZEK. *Arch. Eisenhüttenw.* **4**, 105–10 (1930).—Normalized flat test pieces of low-C steel (0.1% C), Mo steel (0.15% C, 0.34% Mo) and Ni steel (0.28% C, 2% Ni) were subjected at const. temp., at intervals of 50° between 300° and 500°, to definite loads, successively increased. The max extension reached at each load was recorded as a function of the time, and from the data obtained, curves were plotted giving the relation between load and elastic strain and between load and total extension. Within the range of temps. investigated the Mo steel proved to be most resistant to permanent flow under the loads applied. At 350° under a load of 175 kg./sq. mm. applied for 504 hrs. the Mo steel had not yet attained the condition of plastic flow. The elongation at rupture was 0.172%. H. S. VAN KLOOSTER

Steel hardening. H. ESSER AND W. EILENDER. *Arch. Eisenhüttenw.* **4**, 113–44; *Stahl. u. Eisen* **50**, 1616–7(1930).—After having proved in preliminary quenching tests that the heat effects occurring during the quenching of steel specimens in water cannot be detd. accurately, the quenching was performed by means of gas. The heating and quenching of the samples were performed in a vacuum in a container designed for this special purpose. The specimens used were either thin sheets (0.5 to 1 mm. thick, 1–2 mm. wide) or small balls 1–2 mm. in diam. Quenching curves with varying cooling velocity were taken on C steels from 0.01 to 1.75%. The results permit certain conclusions to be drawn as to the nature of Ar′ and Ar″. The heat effect occurring between 300° and 400° with cooling velocities of about 100° to 200°/sec. is assumed to be a tempering effect due to the essentially decreased cooling velocity within this temp. range. In considering these results, the authors arrive at a new explanation for the causes of temper brittleness. A hardening diagram for a cooling velocity of 1000°/sec is designed, indicating that the heat effects during quenching are similar to the transformations of the Fe–C diagram. It must probably be assumed that martensite is not a pseudo solid soln. but a heterogeneous submicroscopical mixt. of α-iron and cementite. It is furthermore concluded that all Fe-C alloys, even those with very low C contents, are hardenable if they are sufficiently rapidly cooled. The microscopical investigations are in accordance with the results of the thermal analysis. The development of a new theory of hardness is attempted, which explains the hardness in quenching the austenite with crit. velocity by the following 2 factors: (1) the high degree of dispersion of the cementite; and (2) the pronounced distortion of the α-lattice during the γ-α transformation and the cementite pptn. in the temp. range of a decreased plasticity of the steel. Both factors account for the hardness. G. G. NEUENDORFF

Stainless steels used in heavy machining. CHARLES E. HERD. *Metal Progress* **19**, No. 1, 44–9(1931).—Special applications in paper-mill machinery and hydraulic turbines are described. W. A. MUDGE

Steels used in Ford industries. J. L. MCCLOUD. *Metal Progress* **19**, No. 3, 32–9 (1931).—A general review. W. A. MUDGE

Steel and its heat treatment for parts that must resist wear. H. W. MCQUAID. *Heat Treating and Forging* **16**, 1159–62(1930); cf. *C. A.* **25**, 2090.—The different steels and treatments which can be used for obtaining hard surfaces are enumerated, discussed, and classified according to their relative cost. J. BALOZIAN

Creep of steel at elevated temperatures. P. G. MCVETTY. *Mech. Eng.* **53**, 197–200(1931).—The principles underlying the creep of steel at elevated temps. are discussed. The phenomenon of creep is defined, typical creep curves are shown and interpreted, and the metallurgical significance of creep phenomena and its significance to the designer are pointed out. G. G. NEUENDORFF

Some long-time tension tests of steels at elevated temperatures. J. J. KANTER AND L. W. SPRING. *Proc. Am. Soc. Testing Materials* **30**, Pt. I, 110–32(1930).—Very detailed evidence is given to show the value of a logarithmic method of plotting for comparing strain-hardening effects and to bring out the fact that rates of creep are not necessarily const. Long-continued tests often show a decreasing rate because of strain-hardening.

Comparison of short-time tensile and long-time flow tests shows that at the higher temps. the short-time tests do not reliably reflect the properties. At the higher temperatures large grain size, whether obtained in cast as compared with wrought alloys, or by annealing as compared with quenching and drawing, or with rolling without annealing, tends to reduce creep. Step-loading, running awhile at one load and then increasing the load on the same specimen, may give misleading results. The discussion deals primarily with methods, but the curves give much actual data on the flow properties of carbon and Ni-Cr cast steels and on wrought carbon, Cr-Mo, Ni-Cr, stainless and 18–8 Cr-Ni steels. Some of the curves show results from observation of the same specimen for a year or more. H. W. GILLETT

Structural changes in annealed soft steel. W. HEIKE AND W. BRENSCHEIDT. *Arch. Eisenhüttenw.* **4**, 99–103(1930).—Mild steel (0.16% C, 0.02% Si, 0.35% Mn, 0.065% P and 0.007% S) was cold-rolled to different degrees (as far as 60% reduction in area) and annealed in limestone, in air and in a lead bath for periods up to 100 hrs. at temps. between 730° and 800°. Large columnar grains appear on the periphery at a degree of deformation around 3%. The phenomenon disappears when the reduction in cross-sectional area reaches 6%. The columnar growth can be used as an indication of previous cold-work deformation, in conjunction with Fry's method of etching. Grain growth occurs also in the interior but uniformly, as soon as the C has diffused towards the outside. The loss of C, even in an annealing bath of lead, is about 40%. Prolonged annealing slightly below A_3 in an oxidizing atm. at degrees of deformation above 30% produces unusually large grains which originate in spots that are rich in P. When the annealing process is carried out between A_1 and A_3 the C is displaced from the spots that contain a considerable amt. of P and grain growth occurs as a result of the diffusion of P. H. S. VAN KLOOSTER

Thermodiffusion of elements in steel. II. JOHN H. HRUSKA. *Heat Treating and Forging* **16**, 1530-3(1930); cf. *C. A.* **25**, 1200. —The thermodiffusion of C in carburizing and cyaniding, and of O, and of decarburization as a thermodiffusion phenomenon are discussed J. BALOZIAN

Nitrided steel and its properties. J. H. HIGGINS. *Heat Treating and Forging* **16**, 1527–9(1930).—The existing practical conditions confronting the com. nitrider are discussed. J. BALOZIAN

German versus American sheet steel. EDWARD S. LAWRENCE. *Heat Treating and Forging* **16**, 1156-8(1930).—The av. processing of an extra-deep drawing auto-body sheet as manufd. in this country and in Germany is compared. J. BALOZIAN

Characteristics of rimmed steel. EDMUND C. BITZER. *Blast Furnace Steel Plant* **19**, 249–51, 415–7, 422(1931) —Rimmed steel is one which has been partially deoxidized either in the furnace or in the ladle and is poured in this condition. C, Mn and S have a profound effect upon the rimming properties of the steel. Too much Mn and C will cause the steel to grow without any indication of rimming action. 0.06% S would cause the rimming action in an ordinary open-hearth heat to be too weak and the blowholes in the ingots would be too near the surface. Al facilitates the pouring of certain grades of rimmed steel whose C is low. It is added in shot form according to the judgment of the pourer. It makes the metal pour quietly, thus cutting down the pouring time. Segregation is the principal evil in rimmed steels. Since different heats of rimmed steel segregate to different degrees, it seems logical that a more detailed knowledge of the effect of FeO content in the metal would lead to the mfg. of a better grade. A method has been developed for detg. FeO in liquid steel. The importance of temp. in the mfg. of rimmed steel cannot be over-emphasized, as excessive temp. has probably ruined more steel than the total amt. spoiled from other causes. The advantages of rimmed steel are its low cost and use of less deoxidizer; it contains a min. of nonmetallic inclusions; the yield from ingot to finished product is greater because of the absence of pipe in properly made steel Better control is needed to decrease segregation, thin-skinned ingots and over-oxidation. H. C. PARISH

Crystal structure of martensite. E. ÖHMAN. *Nature* **127**, 270–2(1931).—The present knowledge of tetragonal martensite is summarized and results of earlier investigators are reviewed with reference to C content and lattice dimensions. Ö employed Cr K-radiation and obtained photograms of quenched steel specimens in which the line (101) of the tetragonal phase is sepd. from the γ-Fe line (111). It was thus possible to det. the lattice dimensions of the tetragonal structure. Results are in agreement with those of Kurdumoff and Kaminsky that the tetragonal martensite is a supersatd. soln. of C in α-Fe. Ferrite and tetragonal martensite are thus one and the same phase, but as they are often present in one and the same specimen as sep constituents, it seems convenient to denote the tetragonal phase as α'. Westgren and

Phragmen suggested that the C atoms dissolved in γ-Fe do not occupy any points of the face-centered lattice, but are statically distributed in the interstices between the Fe atoms. Seljakow, Kurdumoff and Goodtzow suggested that the same might be the case in the α'-phase, but Ö. thinks this improbable as the space available for the C atoms would be extremely small. Another probable explanation is that there is a complex substitution in such a way that a group of 2 C atoms is substituted for 1 Fe atom in the lattice. These compds. have a tetragonal structure in which the C_2 group is oriented parallel to the tetragonal axis, an explanation which holds equally well for tetragonal martensite. By density measurements, it is shown that the assumption of a complex substitution of C atoms is in good agreement with x-ray intensities. The only suggested structure of tetragonal martensite which explains the observed density, the increase of vol. with the C content, and the elongation of one of the crystallographic axes may be described as follows: In the body-centered lattice groups of 2 C atoms statically distributed replace some of the Fe atoms. The C atoms are most probably oriented in such a way that the axes of the C_2 groups are parallel to the tetragonal axis of the lattice. G. L. CRAIG

Effects of alloys on rolled and cast steels. R. C. GOOD. *Iron & Steel Can.* **13**, 121–2, 141–2(1930); *Can Machinery* **41**, No. 16, 39–40.—A brief summary is given of the reasons for using Cr, Ni, Co, Mo, Mn, V and Si, individually and in certain combinations, as alloys, in rolled and cast steels. DOWNS SCHAAF

Some lesser known facts concerning alloy steels. J. H. ANDREW. *Trans. Inst. Eng. Shipbuilders Scotland* **73**, 166–98(1929).—See *C. A.* **24**, 810. A. N. H.

Relative merits of some different alloy steels with respect to certain mechanical properties. BRADLEY STOUGHTON AND WILBER E. HARVEY. *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 241–57(1930).—Data in the literature are studied by the application of various "quality factors," such as tensile times elongation, elastic limit times reduction of area, tensile times Izod, etc., in an effort to find a quality factor that will pick out superior steels. The data are tabulated in various ways. In one classification such widely varying compns. as C 0.47, Cr 0.51 and C 0.09, Cr 16.0% are classed together as Cr steels. Variations in methods of testing for elastic limit, in notches used on Izod bars, etc., in size of bar from which a test specimen was taken, whether heat-treated in test bar or larger size, etc , are not given and these variations probably affect the tabulations. No attention is paid in quality factors employed, to cleanliness of steel, ease of rolling, response to heat treatment, depth hardening, weldability, machinability or cost, though attention is called to the fact that some of these are important. Numerous data are recorded on Ni, Ni-Cr and Cr-V steels of tensile strengths from 100,000 to 300,000 lb./sq. in. with references to the original sources of the data. No conclusions are drawn as to which, if any, "quality factor" is to be preferred. H. W. G.

Can residual analysis by decomposition with chlorine be applied to alloy steels? ROLAND WASMUHT. *Arch. Eisenhüttenw.* **4**, 155–9(1930).—In order to apply this method to the detn. of metal oxides the alloy and any metal carbides which may be present must be completely decompd at temps at which the oxide is not yet attacked by the Cl. A no. of alloys and metal carbides and also a number of oxides, by themselves as well as in the presence of C, were investigated for their resistance against Cl at various temps. The oxides of W, Mo, Ni, Co cannot be detd. by this method, as they are attacked by the Cl at temps. at which the carbide or the metallic alloy are not yet completely decompd. It seems possible to det. Cr oxide if a decompn. temp. of 500° is chosen. Such residual analyses were made on Cr steels and showed that the materials contained varying quantities of Cr oxide, from which conclusions could be drawn as to the behavior of the alloy. The use of chips or metal pieces as initial material for the analysis is briefly discussed. LEOPOLD PESSEL

Alloy steels in the railroad field. CHARLES MCKNIGHT. *Trans. Am. Soc. Mech. Eng., Railroads* **52**, 81–93(1930).—There is an increasing interest in the use of alloy steels for railroads. They are used purely as a matter of economy. Better work must be done at the same cost or the same work at less cost. The use of alloy miscellaneous castings materially cuts down weight with the same strength and same cost as C steel castings. C steels are used for special applications. Semi-alloy steels are slightly more expensive than C steels and have slightly better properties. Some of the uses include boiler materials, forgings and castings. Corrosion-resisting materials, nitriding and miscellaneous materials are discussed and the economies of each are given. R. RIMBACH

Preliminary report on the behavior of copper steel rails. FRANCESCO ABBOLITO. *Rivista tec. ferrovie ital.* **37**, 292–6(1930).—Cu steel rails (contg. 0.08–0.23% Cu and having 66–83.5 kg./sq. mm. strength) were examd. after 16 yrs.' service: a loss in the

breaking strength of 1.4 kg. was found, and an av. loss of 4.2 sq. cm. on the original section of 47 sq. cm. G. A. BRAVO

Results of laboratory tests and practical experience with rails on Swiss railways. P. LUCCHINI AND M. ROŠ. *1st Communications New Intern. Assoc. for Testing Materials* **1930A**, 190–212(in German).—Simultaneous tests in the Swiss Federal Testing Laboratory and the Swiss Federal Railways on various mild steel rails of known compn., especially with regard to wear, showed that hard steel rails and heat-treated rails of great hardness have a greater resistance to wear than older and newer rails of lower hardness and strength. E. M. SYMMES

Alloy cast iron and high-strength cast iron in the United States of America. F. B. COYLE. *1st Communications New Intern. Assoc. for Testing Materials* **1930A**, 35–48; cf. *C. A.* **23**, 4175.—The extent of development of alloy cast Fe in the U. S. A. is described. The alloying elements are carbide-forming and graphitizing. There is described the general effect of alloying elements on grains, tendency to chill, hardness, machinability, resistance to wear, d. and strength, and the strength limits of plain and ordinary alloy Fe are given. To develop extremely high strength, superheating, partial malleabilization, low-C cupola Fe and white cupola Fe graphitized by ladle addns. may be used. E. M. SYMMES

Alloy additions improve gray iron pressure castings. F. J. MCGRAIL. *Foundry* **59**, 52–5(1931).—Ni and Cr alloys in the form of shots are sprinkled into molten metal. These 2 metals eliminate the use of expensive chills, and the grain structure is uniform to the center of the test pieces. Photomicrographs are shown of test pieces which broke around 5000 lb. on the transverse test. H. C. DUUS

The relations between structure and properties in metallic alloys. A. GUERTLER. *1st Communications New Intern. Assoc. for Testing of Materials* **1930A**, 320–7.—A philosophical discussion of individual crystals of pure metals, of compds., of solid solns. and of aggregates. H. W. GILLETT

Heat-resisting alloys in furnaces. L. J. STANBERY. *Heat Treating and Forging* **16**, 1031–5; 1191–2, 1195–6(1930).—The principles involved, the effect on the properties of the alloy of various chem. elements and of heat treatment are discussed. J. B.

The influence of silicon and manganese on the type of solidification of iron-carbon alloys. OTHMAR VON KEIL AND FRANZ KOTYZA. *Arch. Eisenhüttenw.* **4**, 295–7(1930). The influence of Si and Mn on the type of solidification and the carbide decompn. of Fe-C alloys is investigated metallographically and by cooling-curve detns. The fusions were made at 1350–1400°, and the cooling velocity was 30°/min. (av.). At these cooling velocities Fe-C-Si alloys of hypo-eutectic compn. show metastable solidification with subsequent carbide decompn., and only in the hypereutectic alloys does the stable solidification appear. By addn. of Mn the white solidification is more stable at low C contents, while at approx. eutectic concns. the stable phase is favored. Also, the field of metastable solidification with subsequent decompn. is smaller with increasing Mn content. J. BALOZIAN

The alloys of iron and manganese. V. N. KRIVOBOK. *Heat Treating and Forging* **16**, 1538–40(1930).—The heat treatment and metallography of Fe-Mn alloys are discussed. Micrographs (9) are shown. J. BALOZIAN

Dimensional stability of heat-treated aluminum alloys. J. D. GROGAN AND D. CLAYTON. *J. Inst. Metals*, Advance copy No. 553, 28 pp.; *Engineering* **131**, 371–3(1931).—It was found that the change in length of both cast and forged heat-treated Al alloys over a period of years was inappreciable. Changes in length on machining these alloys, however, may occur. Samples of Y-alloy, duralumin and 25S 3 in. in diam. by 5 in. long were heat-treated and machined into dumb-bell form. As the outer surface was removed appreciable shrinkage occurred in the fully aged alloys. The shrinkage was greatest in those quenched in cold water, less in those quenched in oil and almost negligible in those quenched in boiling water. The decrease in length in some cases amounted to almost 0.020 in. Tensile and hardness tests indicated that the alloys quenched in boiling water were as effectively hardened as those quenched in cold water. Dimensional changes on machining did not occur in annealed alloys. The corrosion resistance of the hot-water quenched alloys may be low, and the greater resistance of the cold-water quenched alloys may result from compressive stresses in layers near the surface, which heal intercryst. corrosion cracks. J. L. GREGG

A note on the silver-rich aluminum-silver alloys above 600°. T. P. HOAR AND R. K. ROWNTREE. *J. Inst. Metals*, Advance copy No. 555, 6 pp.(1931).—Alloys up to 15% Al were studied by thermal and microscopic methods. The results substantiate Petrenko's diagram except that the diagram is shifted to higher temps. The diagram is similar to the Cu-Al diagram. J. L. GREGG

Influence of heat treatment on resistance of aluminum-silicon alloys containing up to 2.5 percent silicon. L. GUILLET AND M. BALLAY. *Rev. métal.* **27**, 398–403 (1930).—See *C. A.* **24**, 5702. E. J. C.

An air-hardening copper-cobalt alloy. CYRIL S. SMITH. *Mining and Met.* **11**, 213–5(1930).—A Cu alloy containing between 1 and 5% Co when quenched sufficiently rapidly from a high temp. remained in the soft alpha condition. The quenched alloy on re-annealing at a suitable temp. was hardened by submicroscopic pptn. of the Co-rich solid soln. in a manner similar to duralumin. The alloy softened again if the annealing temp. was too high, as a result of the coagulation of the ppt. A peculiar scale resulted when the alloy was annealed in an oxidizing atm. Underneath the usual black and red scale, there appeared a layer of tightly adherent metallic "sub-scale" which was detached only when the metal was very severely distorted. It consists of polygonal grains continuous with the underlying metal but containing innumerable black particles of Co oxide. F. W. BOECH

Rolling of alloys of copper and phosphorus containing up to 5 percent of phosphorus. OWEN W. ELLIS. *J. Inst. Metals*, Advance copy No. **551**, 6 pp.(1931).—Contrary to recent reports, Cu contg. as much as 5% P can be rolled. Sheets for brazing have been rolled to 0.015 in. The Cu-P alloys were rolled at a temp. of 450° or above to between 0.02 and 0.04 in., and then rolled cold. A strip of the 5% P alloy 0.018 in. thick had a tensile strength of 88,000 lb./sq.in. and practically no elongation. J. L. GREGG

Nickel alloys. W. R. BARCLAY. *Metal Ind.* **37**, 414–6, 437–40(1930).—A historical review of B.'s 35 years of personal experiences in the manuf. of Ni alloys. The importance of const. study and research is insufficiently realized. O. M. SMITH

Etching nickel and its alloys. W. A. MUDGE. *Metal Progress* **18**, No. 6, 72–3 (1930). W. A. MUDGE

The advantages of lead-antimony and lead-antimony-cadmium alloys over lead in the manufacture of sheaths for telephone cables. H. GODIN. *Rev. univ. mines* [8], **5**, 106(1931).—The failure of cable sheath has been found to be largely a matter of fatigue. On the basis of this property, an alloy of Pb 99.25, Sb 0.5 and Cd 0.25% has been found superior to the 1% Sb alloy and very much better than Pb. R. S. DEAN

Special bronzes. WILLI CLAUS. *Metallbörse* **20**, 1769–70, 1825–6, 1881–2, 1937–8, 1993–4, 2049–50, 2105–6, 2161–2, 2217–8, 2274–6, 2331–2, 2386–7(1930); cf. *C. A.* **23**, 5144.—Special bronzes are defined as alloys contg. at least 78% of Cu and other metals besides Zn. The special bronzes discussed are those contg. Pb, Mg, Cd, Si, Mn, P, Al, Ni, Sb, As, Bi, Co, Ag, Fe, Cr, W, V, Mo, Ti and Be. A complete discussion of the properties of these various special bronzes is given but no new data. R. S. DEAN

Carburizing with gas in underground retorts. W. F. MCNALLY. *Metal Progress* 19, No. 1, 39–43(1931).—Gas carburization with natural gas, propane and dehydrated city gas is superior to solid material carburization because of lower labor, fuel, carburizing media and container costs together with greater uniformity and flexibility. W. A. MUDGE

Pickling of metals. E. GIRARD. *Rev. chim. ind.* **40**, 7–12(1931).—A review. P. THOMASSET

Some practical features of wire pickling. W. G. IMHOFF. *Wire* **5**, No. 3, 77, 79–80, 94–5(1930). E. I. S.

How to select thin plate for deep drawing. H. T. MORTON. *Metal Progress* **18**, No. 6, 54–9(1930).—A discussion is given of chem. compn., slag inclusions, surface decarburization and annealing upon drawing quality. W. A. MUDGE

Coatings, corrosion protection and coloring of aluminum. HERBERT KURREIN. *Metallwirtschaft* **9**, 1009, 1031–2, 1049–50(1930).—A review. LEOPOLD PESSEL

Theory of the rust-protective action of protective coatings. W. BECK. *Korrosion u. Metallschutz* **6**, 229–30(1930); *Gas J.* **193**, 216–7(1931).—By means of colloid-chem. considerations an attempt is made to explain the mechanism of the protective action of protective coatings. An explanation is given of why, in spite of a very distinct lack of elec. insulation, an effective rust protection may exist. Adsorption layers may be formed on the surface of the metal which may have great protective value and yet, on account of their great thinness, only a very small elec. resistance. The impossibility is emphasized of drawing conclusions from the poor insulating qualities of the protective coating as to its protective value. LEOPOLD PESSEL

Selective solution of magnesium corrosion products. L. WHITBY. *J. Soc. Chem. Ind.* **50**, 83–5T(1931).—A boiling 20% soln. of pure CrO_3 may be used to remove corrosion products rapidly from Mg and Mg-base alloys. The soly. of the metal in acid is negligible for most purposes. If Cl^- is present its activating effect may be inhibited

by adding small quantities of Ag_2CrO_4 to the CrO_3 soln. SO_4^{--} exerts no activating action when present in small quantities. B. E. ROETHELI

Initial corrosion rates of metals. R. H. BROWN, B. E. ROETHELI AND H. O. FORREST. *Ind. Eng. Chem.* 23, 350–2(1931).—The initial corrosion rates of Al, Zn, Fe, Cu, Ni, Sn and Ag in oxygenated water were studied. All the metals investigated were shown to have finite corrosion rates. Tendencies of the metals to corrode (calcd. as free energy decreases for the cells:

$$\left(\begin{array}{c|c|c} M(s) & \begin{array}{l} M(OH) \text{ satd.} \\ \text{Satd. soln. } O_2(0.21 \text{ atm.}) \end{array} & O_2(0.21 \text{ atm.}) \end{array}\right)$$

were obtained and found to be in better agreement with the facts than tendencies obtained from consideration of the molal e. m. f. series. Corrosion rates decreased with immersion time. This was attributed to the formation of films which reduced the rate of diffusion of ions and dissolved O_2. B. E. ROETHELI

Metal corrosion. G. CHAUDRON. *La Nature* 1930, I, 172–4; *Wasser u. Abwasser* 27, 171.—The electrochem. corrosion theory as applied to metals and the importance of O_2 in corrosion are explained. Corrosion is best detd. on metals by detg. the loss of wt. during exposure under fixed conditions of temp., etc. Protective alloys and coatings are discussed. C. R. FELLERS

Influence of stress on corrosion. D. J. MCADAM, JR. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. 417, 39 pp.(1931); cf. *C. A.* 24, 2412.—Special attention is given to Ni, Al bronze, stainless Fe, nitrided steel and Muntz metal. Each expt. was in 2 stages: (1) a corrosion stage, in which the specimen was corroded with or without cyclic stress; (2) a fatigue stage, in which the specimen was tested to fatigue failure and the fatigue limit was estd. The lowering of the fatigue limit is used as a measure of the "damage" due to corrosion. Diagrams of 3 types are presented: type 5 illustrating relative influence of stressless corrosion and corrosion under cyclic stresses in causing damage; type 10 illustrating influence of cycle frequency on net-damage; and type 11-a illustrating influence of stress range. These diagrams, in addn. to diagrams for steels, Al alloys and Monel metals presented in previous papers, illustrate the behavior of a great variety of metals under similar conditions of corrosion. The rate of net damage varies as the third to at least the fifth power of the corrosion stress, depending on the metal, cycle frequency and corrosion conditions. The general conditions favoring intercryst. corrosion are discussed. Application of stress-corrosion data to design, construction and operation of machinery and structures is discussed briefly. C. L. MANTELL

The effect of artificial aging upon the resistance of superduralumin to corrosion by sea water. K. L. MEISSNER. *J. Inst. Metals*, Advance copy No. 557, 15 pp.; *Engineering* 131, 406–8(1931); cf. *C. A.* 25, 62.—Specimens of superduralumin (0.8% Si) that had been quenched from 500° and aged for 20 or 40 hrs. at temps. up to 200° were exposed in the North Sea for 3 months. During exposure they were under water for 7 or 8 hrs and in the air for 4- to 5-hr. periods. The corrosion was detd. by appearance, change in weight, change in tensile properties and microscopic examn. The samples aged at 125° and 145° were badly pock-marked. Tensile tests indicated that these samples had been most severely attacked. Microscopic examn. showed that these samples were corroding at the grain boundaries and that the pock-marks were caused by chunks of Al falling off. In such an alloy there is therefore a crit. tempering range between 100° and 150° at which the corrosion resistance is at a min. This range is just below the crit. hardening temp. J. L. GREGG

First report of the corrosion of pipes sub-committee. ALBERT STOKES, *et al.* *Inst. Gas. Eng.* 1930, *Communication* No. 20, 10 pp.—The effects of various coatings on wrought Fe and steel were detd. in 2 types of tests. (*a*) The coated metal was placed in soil and made the anode of a closed elec. system. The source of current was a 6 v battery. The current was measured at different intervals of time and the resistance of the coating calcd. (*b*) The e. m. f. differences between a coated and uncoated specimen were measured at various times. The resistance of the coating decreased with increasing H_2O content while the e. m. f. measurements showed increasing values. Painted pipes showed much greater resistance to the flow of current than bare pipe. Pipes covered with paper wrappings and paints were about 50 times as resistant to the flow of current as paint coatings. Deep pits occurred in the metal surfaces where the coatings were broken. Cement coatings were found temporarily resistant to stray current electrolysis. Also in *Gas J.* 192, 725–9(1930). B. E. ROETHELI

Error of averages and its application to corrosion tests. C. H. HUMES, R. F. PASSANO AND ANSON HAYES. *Proc. Am. Soc. Testing Materials* 30, Pt. II, 448–55 (1930).—If all samples of a given material in a corrosion test failed at the same time,

only one sample would be required. When failures occur over a time range the no. and area of samples that must be tested to give a true measure have to be detd. by the methods of statistics. The mathematics of the procedure needed to arrive at the no. of samples required for reasonable assurance of a given desired accuracy in the mean of the exptl. data are discussed. H. W. GILLETT

Outline of welding and allied processes. F. T. LLEWELLYN. *Metal Progress* **18**, No. 6, 95–104; **19**, No. 1, 51–60(1931).—This is an outline of the practice recommended by the Am. Soc. Steel Treating comm. W. A. MUDGE

Electric arc welding of aluminum. W. M. DUNLAP. *Welding* **1**, 762–6(1930); cf. *C. A.* **24**, 2975, 5277.—A discussion of equipment, flux, electrodes, procedure control and advantageous application. E. I. S.

Metallurgy of the fusion welding process. F. RAPATZ. *Stahl u. Eisen* **51**, 245–53 (1931).—The fusion welding process is reviewed. The desirable qualities of welding rods are: good melting off, that is the rod should form uniform drops in the arc and the cast should be free of pipes; then good fusing together, that is a good alloying of the weld with the rest of the material; the deeper this "burning in" the better the weld. For elec. welding if d. c. is used with the electrode as the neg. pole, bare rods or wires are required contg. non-metallic admixts., best in the form of non-metallic cores. This method is best suited for soft ingot steel. For steel with higher C content and alloy steels this welding on the neg. pole cannot be used. If the pos.-pole welding is used for all types of alloyed steel, good melting off of the rods is obtained. However, the alloying, the "burning in," is poor. This method is best suited for high-C steel. For a.-c. welding, rods with an outside cover, consisting of either asbestos or a mixt. of Fe oxide, materials giving an exothermic reaction and metals readily combining with O, such as Al or ferromanganese, are used. Wires or rods with non-metallic core can be used also. Plain steel rods or wires cannot be used. In d.-c. welding, with well-covered wires or rods, the electrode should be the pos. pole. In gas fusion welding, the rods should be free of non-metallic admixts. The compn. of the weld depends on the compn. of the welding rods, on the gas absorption and oxidation of the various constituents of the material welded and on the alloyed "burnt in" layer. The effect of the alloying elements, such as Ni and Cr, on the characteristics of the welded part is discussed. There is an overheated zone around the weld, then a normal annealed, a slightly affected and in some cases, a blue brittle zone. The area of this heat-affected zone is greater in gas fusion welding than in elec. welding. The Brinell hardness figures for the various zones are given for both cases. In highly alloyed steel a very decided effect on the area around the weld is obtained, because of air hardening. On account of the zones of different hardness, great care should be taken in the evaluation of the results of the various bending and tensile tests. J. A. SZILARD

Ore flotation. A. BORSIG G. M. B. H. Ger. 515,757, July 24, 1926. Addn. to 446,086. App. for sweeping out the slime from clarifying vessels is described.

Flotation apparatus for concentrating ores, etc. FRANK E. ELMORE. Ger. 518,301, Aug. 13, 1927. See Brit. 275,778 (*C. A.* **22**, 2296).

Flotation apparatus for concentrating ores. LÉON C. V. BENETT. Fr. 37,243, July 22, 1929. Addn. to 568,182.

Extracting metals. RUDOLF SCHAUR and KLEMENS SCHUMACHER. Austrian 121,535, Oct. 15, 1930. In extg. metals from oxide ores by blowing reducing gases through the fused ore, *e. g.*, in effecting the reaction $FeO + CO \rightleftharpoons Fe + CO_2$, the metal is continuously withdrawn from the reaction, in order to shift the equil. point in the desired direction. This may be effected by maintaining such a reaction temp. that the ore remains liquid but the metal solidifies. Also, a converter may be used to which the reducing gases are fed at points above the bottom, the metal sinking to the bottom out of contact with the gases. Powd. C may be blown in with the gases.

Extracting metals. RUDOLF SCHAUR and KLEMENS SCHUMACHER. Austrian 121,523, Oct. 15, 1930. In the extn. of Fe and other metals by blowing highly heated reducing gases through molten ore, the temp. of the ore is maintained by passing an elec. current and (or) high-frequency current through it. Suitably, the ore is melted in a hearth furnace and then transferred to a tiltable elec. furnace to which the reducing gases are supplied.

Treating ores or concentrates of copper and nickel, etc. E. A. ASHCROFT. Brit. 338,556, Aug. 20, 1929. Material contg. Cu or Ni sulfides or both, or Cu or Ni oxidized compds., together with added S such as Fe sulfide, is treated with air or O at 600° to convert the Cu and Ni to sulfate (without disturbing or rabbling the materials during the reaction). The heat of reaction is usually sufficient to maintain the temp. after the reaction is started, and the charge may be covered by a thin layer of inert material. When Ni is present, $FeSO_4$ or $FeCl_2$ may be added with advantage. Most of the Fe present remains in the residue as oxide on leaching, together with sulfates of gang materials such as $CaSO_4$. O or air enriched with O may be used to start or assist the reaction, and various other details and modifications of app. and procedure are described.

Leaching copper and nickel sulfide ores. I. BÁLINT. Hung. 101,498, Feb. 15, 1930. The ores are leached at a temp. higher than 100°, under pressure, with FeCl or $CuCl_2$ as solvent.

Leaching copper sulfide ores. I. BÁLINT. Hung. 101,495, Oct. 5, 1929. The used CuCl soln. may be regenerated by sepg. it into part (1), contg. as much Cu as was dissolved out of the ores, and part (2), contg. as much as was originally used for leaching. Cu is sepd. from part (1) by cementation. The remaining soln is united with part (2) and the mixt. transformed to $CuCl_2$ by aeration. The iron hydroxide ppt. formed in the cementation can be sepd.

Combined reduction of ores and hydrogenation of carbonaceous materials. J. L. FOHLEN. Brit. 339,276, July 25, 1929. Ores such as Ni ore are reduced to metals, and carbonaceous materials (such as lignite and its distn. products) are hydrogenated to form volatile fuels, by first reducing the ore in the presence of the carbonaceous material or its distn. products and H heated to about 350–400°, then allowing the temp. to fall to 150–300° and hydrogenating the gaseous products of the reaction by contact with freshly reduced metal. An arrangement of app. and various details of procedure are described, and the process may be applied to the production of hydrogenated products from anthracene, etc.

Treating sulfide ores. NATIONAL PROCESSES, LTD., and T. B. GYLES. Brit. 338,886, Aug. 27, 1929. Sulfide ores are blast-roasted or sintered together with a coarse granular material, such as sintered ore, and a small porportion of sulfate or sulfite of a metal other than Fe or an alkali or alk. earth metal (suitably sinter from a previous operation treated so that it contains $ZnSO_4$ with or without $ZnSO_3$). Sulfurous gases may be passed over the sinter (preferably moistened) as described in Brit. 321,390 (*C. A.* **24**, 2515) or the gas may be passed over the mixt of raw ore and diluent in a mixer from which it is fed to the sintering app. (or $ZnSO_4$ liquors may be used instead of sulfurous gases).

Direct production of metals such as iron from ores. THOMAS ROWLANDS. U. S. 1,795,681, March 10. Ore such as Fe ore is passed through preheating, reduction and cooling zones of a rotary furnace and carbonaceous fuel such as coal is subjected to low-temp. carbonization in the cooling zone by heat from the treated charge that has passed through the reduction zone but without direct contact with the charge; ore reduction in the reduction zone is effected at comparatively low temp. and considerably below melting temp. by the reducing gases and solid fuel from the low-temp. carbonization. App. is described.

Production of pig iron from ores poor in iron and from iron-containing bauxites.

I. PFEIFER. Hung. 100,509, March 12, 1929. Ores contg. 30–35% or less Fe are mixed with slag-forming materials, *e. g.*, silica or alumina, and heated in the presence of CO or hydrocarbons. The iron produced is satd. with C and the m. p. is thus lowered to 1150–1200°. The slag-forming material should be so selected that the slag also melts at this temp. and thus can be easily sepd. from the melted iron. For Fe-contg. bauxites, the slag-forming material should contain alkalies, *e. g.*, Na_2CO_3, which lowers the m. p. of alumina by formation of Na aluminate.

Direct production of cast iron from ore. J. E. FLETCHER. Brit. 338,535, Aug. 19, 1929. Reduction is effected in one or more primary rotary furnaces and the molten product is passed into a secondary furnace in which it is further heated with any accompanying slag and with desired addns. of modifying or alloying materials. Some mention is made of the applicability of the process to production of metals other than iron.

Preparing cast iron from ores. A. G. KHOTYAN. Russ. appl. 24,991, Mar. 27, 1928. A mechanical device is specified.

Extraction of iron from its ores. VEREINIGTE STAHLWERKE A.-G. Ger. 518,392, Sept. 17, 1927. See Fr. 35,306 (*C. A.* **24**, 3746).

Reducing oxide ores of metals such as iron. SAMUEL L. MADORSKY (to Gathmys Research Corp.). U. S. 1,796,871, March 17. A reducing gas is passed through molten ore in part of a furnace (details of construction of which are described), and the waste gas passing from the ore is passed over molten ore in another part of the furnace to effect partial reduction of the ore. Cf. *C. A.* **24**, 4499.

Titanium recovery from ores. OSCAR T. COFFELT. U. S. 1,795,361, March 10. A Ti ore contg. Fe is digested with acid such as 75–90% H_2SO_4 and the sol. salts thus formed are dissolved, the Fe and some of the Ti are reduced (suitably by use of Fe or Zn) and an NH_4 halide such as NH_4Cl is added in an amt. equal to the Ti present, water is added to double the volume, followed by boiling and maintaining the diln. until a ppt contg Ti in combination with O is formed, and this ppt. is removed.

Tungsten from ores. CHARLES V. IREDELL (to Westinghouse Lamp Co.). U. S. 1,796,026, March 10. Alk solns. such as may be formed by treating a W ore with alkali are treated to reduce their alkalinity to 0.3–0.7% free alkali (using phenolphthalein as indicator), and a Ca salt such as $CaCl_2$ is then added to the soln. to ppt. the W content. A product of the formula $CaWO_4.H_2O$ may be obtained.

Acid extraction of metals such as vanadium and zinc from ores. ROYALE H. STEVENS, GERALD C. NORRIS and WM. N. WATSON (to Rhodesia Broken Hill Development Co., Ltd.). U. S. 1,795,412, March 10. The ore is leached with a soln. of relatively low acidity such as a spent electrolyte and the residue is sepd. and releached with acid maintained at a concn. equiv. to not less than 4% H_2SO_4.

Reducing zinc, lead and like ores. FREDERICK L. DUFFIELD. U. S. 1,796,562, March 17. See Brit. 310,252 (*C. A.* **24**, 581). U. S. 1,796,563 relates to an app. similar to the one described in the preceding patent.

Apparatus for reducing ores such as those of zinc. HENRY E. COLEY. U. S. 1,797,130, March 17. Ore is fed into an internally heated reducing chamber provided with an outlet for gang and an inlet for introduction of hydrocarbon material to the ore in the reducing chamber, arranged so that the hydrocarbon material reaches the ore in substantially undecomposed condition; an inlet for combustion air is provided to effect combustion in the reducing chamber of products produced by the cracking of the hydrocarbon material. Various features of construction are described. Cf. *C. A.* 24, 2711.

Obtaining zirconia from ores. CHARLES O. TERWILLIGER (to Ward Leonard Elec. Co.). U. S. 1,796,170, March 10. Finely ground ore is treated with H_2SO_4 and HCl of such strength as to dissolve impurities without dissolving the zirconia, and the soln. is removed and the residue is washed.

Treating metals in ladles (as in an induction furnace). F. KRUPP A.-G. Brit. 339,579, April 30, 1929. When heating molten steel or other metal or alloy in a ladle by the heater described in Brit. 312,063 (*C. A.* **24**, 760), the ladle is placed in a chamber in which a vacuum is created. Cf. *C. A.* **24**, 4468, 4502.

Mold for metal casting. MASCHINENFABRIK ADOLF VIEBAHN. Ger. 502,935, Feb. 3, 1929.

Mold for making tubes by centrifugal casting. SOCIETÀ ALTI FORNI, FONDERIE, ACCIAIERIE E FERRIERE FRANCHI-GREGORINI. Austrian 120,888, Aug. 15, 1930.

Vertical mold for making hollow bodies by centrifugal casting. HEINRICH LENT, HERMANN J. SCHIFFLER and GUSTAV TICHY. Ger. 518,122, Mar. 26, 1929.

Core for centrifugal casting molds. Soc. anon. des hauts fourneaux et fonderies de Pont-a-Mousson. Ger. 518,123, Nov. 6, 1926.

Machines for making hollow bodies by centrifugal casting. Società alti forni, fonderie, acciaierie e ferriere Franchi-Gregorini. Austrian 120,889, and 120,890, Aug. 15, 1930.

Two-part metal founding molds. Henry T. Richardson. Ger. 515,772, May 19, 1928.

Cooling system for casting troughs such as those used in centrifugal casting. Frank G. Carrington (to Ferric Engineering Co.). U. S. 1,796,644, March 17. Various details of app. are described. U. S. 1,796,645 also relates to centrifugal casting app.

Water-cooled die-casting machine. Compagnie générale des conduites d'eau Soc. anon. Ger. 515,799, April 21, 1929.

Metal-casting apparatus. Carl E. Becker. U. S. 1,797,041, March 17. Structural features.

Centrifugal casting apparatus suitable for casting belled pipes. Frank G. Carrington (to Ferric Engineering Co.). U. S. 1,795,637, March 10. Structural features

Centrifugal casting of metal pipes. Soc. anon. des hauts fourneaux et fonderies de Pont-a-Mousson. Brit. 339,095, Dec. 10, 1928. App. and various mech details are described.

Casting metal bushings. Otto Bergner. Ger. 515,801 Sept. 20, 1928.

Casting flanged pipes. Heinrich Nolze. Ger. 515,800, Nov. 10, 1928.

Water-cooled slide-way for ingot-reheating furnaces. Friedrich C. Siemens U. S. 1,795,410, March 10.

Bessemer converter. L. F. Ignatovskii. Russ. appl 67,354, Mar. 30, 1930 Mechanical features

Apparatus for charging the Martin furnace. N. G. Gergesel. Russ. appl 68,282, June 7, 1930. Mechanical details.

Cowl reversible gear for Martin furnaces, etc. O. Reiner. Brit. 338,788, Jan. 10, 1929. Structural features.

Regenerative oven, especially useful as a metallurgical smelting furnace. Walter Alberts and Paul Zimmermann. Ger. 515,855, May 22, 1929.

Oil-fired cupola furnace. Peter Marx. Ger. 515,796, Feb. 2, 1928.

Slag collector for cupola furnace. Friedrich Schinke. Ger. 518,176, Jan. 28, 1927.

Smelting metals such as iron and iron alloys. Carl Brackelsberg. U. S. 1,797,125, March 17. In operating rotatable drum furnaces for melting metals by use of powd. coal as fuel, the fuel is burned directly in the melting chamber of the furnace by the aid of combustion air of such vol. and pressure as to cause the fuel to be burned in suspension and the ashes of combustion to be blown through the outlet of the furnace. App. is described.

Apparatus for charging retorts such as those for zinc production. Walter F. Naylor (to Beardsley & Piper Co.). U. S. 1,796,802, March 17. Structural features.

Modifying the properties of metals. E. G. Herbert. Brit. 338,511, Aug. 16, 1929. Metals (suitably after hardening by working or otherwise) or other substances such as rock salt, sugar or quartz are subjected to the action of a concd. locally generated magnetic field "or like flux or vibration other than heat" (the magnetic field or the like being alternating or rotating).

Fusing refractory metals. Siemens & Halske A.-G. Ger. 518,499, Nov. 2, 1926 Metals such as Ta, W, Th or their alloys are completely fused in strongly cooled crucibles made of materials of lower m. p. than the said metals, *e. g.*, of quartz, Cu or Ag. The metal to be fused may be heated by high-frequency elec. current, and the crucible, if electrically conductive, may be made in a no. of insulated segments.

Metal-reduction bomb suitable for use with calcium and calcium chloride. Wm. P. Kiernan (to Westinghouse Lamp Co.). U. S. 1,795,780, March 10. Various details of stopper construction and fastening are described. The main portion of the bomb may be formed of an alloy resistant to heat and to oxidation such as "nichrome" or "hardite."

Coating metals. Otto Sprenger Patentverwertung Jirotka m. b. H. Fr. 37,112, June 19, 1929. Addn. to 655,786 (*C. A.* 23, 3894). The deposition of MnO_2 on Al, Mg or their alloys is accelerated by adding bi- or ter-valent salts of Mn or ferrous or stannous salts to the baths contg. the permanganate and free acid. Cf. *C. A.* 24, 2097.

Galvanizing pot. O. Middermann. Brit. 339,384, Sept. 20, 1929. Walls of iron

galvanizing-pots which come in contact with the molten Zn are freed from pores by melting their surface layers (suitably with a welding burner or elec. arc).

Rolling thin metal strips or sheets from bars. L. E. BROEMEL. Brit. 338,771, Dec. 18, 1929. Mech. features.

Pointed tubular metal articles such as hypodermic needles. S. J. EVERETT. Brit. 338,592, Aug. 22, 1929. In a process involving swaging, rolling or drawing a tubular billet on a core of metal capable of extreme elongation and retention of tensile strength, such as Ni-Ag or brass (as described in Brit. 210,156), the cored tube is subjected to heat treatment to anneal the core and temper the tube while on the core. Numerous details of procedure for the treatment of different specified metals are given.

Blow-pipe for cutting metals by fusion with the use of oxygen. W. EBERLE. Brit. 339,161, Jan. 15, 1930.

Pickling bath for metals. JAMES H. GRAVELL and ALFRED DOUTY (Gravell to American Chemical Paint Co.). U. S. 1,796,839, March 17. See Can. 302,397 (*C. A.* **24**, 4253).

Bright-annealing metals. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 339,423, Oct. 22, 1928 Various details of app. are described relating to a chamber in which the treated metal is cooled in inert gas the expansion and contraction of which is provided for by connection with a bell gas holder.

Apparatus for annealing sheet-metal strips in coils or bundles. HERMAN C. CAPPEL and OTIS C. GROSS (to Greer Steel Co.). U. S. 1,796,082, March 10. Structural features.

Case-hardening composition. ERNEST C. MOFFETT (to American Cyanamid Co.). U. S. 1,796,800, March 17. See Can. 302,499 (*C. A.* **24**, 4253).

Heat-treating wire and strip material. L. D. WHITEHEAD. Brit. 339,155, Jan. 6, 1930. Wire or strip which is to be subsequently galvanized or otherwise surface-treated is annealed or cleaned (or both) by passing it through a horizontal metal tube arranged in a furnace and contg. molten metal, salts or other suitable liquid material (the 2 ends of the tube being up-turned to retain the contents) Various details of app. are described.

Heat treatment of iron. LINK-BELT Co. Brit. 338,924, May 31, 1929. Malleable cast iron is heated to a temp. (suitably about 800°) sufficient to cause the formation of Fe carbide, cooled or quenched, again heated to a temp. (suitably about 650°) below the C-combining temp., and finally cooled or quenched (after heating to above the galvanizing temp. if the product is to be galvanized by dipping). The first heating may be effected in the presence of a carburizing agent to form a hardened surface on the article. Brit. 338,925 relates to metal similarly treated which is highly resistant to abrasion.

Deoxidizing iron. RUDOLF SCHAUR and KLEMENS SCHUMACHER Austrian 121,730, Oct. 15, 1930. In deoxidizing Fe by blowing reducing gases through the molten metal, the reducing gases are strongly preheated, and the temp. of the metal is maintained by electrically heating, *e. g.*, by means of high-frequency current.

Cementation of iron and steel. HERMANN FREUDENBERG (to Roessler & Hasslacher Chemical Co.). U. S. 1,796,248, March 10. Hardening of ferrous articles is effected by immersing them in a fused salt bath such as soda and NaCl to which is added finely divided C (suitably in the form of charcoal) and an alkali metal hydroxide which serves to enhance the hardening effect.

"Slushing grease" suitable for treating iron or steel to prevent rusting. ARTHUR H. BRANSKY (to Standard Oil Co. of Ind.) U. S. 1,795,993, March 10. A wax such as montan wax is used with Na soaps of sulfonic acid compds. derived from the treatment of hydrocarbon oils with strong H_2SO_4 and with lubricating oil.

Apparatus for heat treatment of steel. V. A. MOZHAROV and I. V. MOZHAROV. Russ. appl. 20,409, Oct. 5, 1927; 32,405, Sept. 10, 1928 and 50,854, July 9, 1929.

Tempering steel strip. ALFRED M. REMINGTON (to Simonds Saw & Steel Co.). U. S. 1,796,304, March 17. The stock is fed slowly through a hardening furnace and the forward end of the stock is fed rapidly into a drawing furnace a distance approx. equal to the effective length of the furnace. App. is described.

Special steel for car wheels, brake shoes, etc. H. J. VAN ROYEN. Brit. 338,528, Dec. 8, 1928. Rails, wheel tires, etc., subjected to hard wear, are made of eutectoid steel contg. double carbides with laminated pearlitic structure. The laminas may contain Fe carbide 75–85 and carbides of metals such as Mn, Cr, W, Mo and V 15–25%.

Steel billets. SAMUEL B. SHELDON. U. S. 1,795,519, March 10. An ingot is formed having an alloy skin which may contain Al alloy and the skin is subsequently removed so that surface imperfections are avoided in the billets formed from ingots thus prepd.

Manganese steel. TAYLOR-WHARTON IRON & STEEL CO. Brit. 339,521, Dec. 31, 1929. For refining the grain structure and improving the properties of Mn steel, it is heated for 12–96 hrs. at 400–600°, slowly cooled, reheated to about 1060° and quenched. Various compns. of steels suitable for this treatment are described.

Heat treatment of alloy irons and steels. P. R. KUEHNRICH and DARWINS, LTD. Brit. 338,912, Aug. 28, 1929. Articles of alloy irons and steels contg. Cr 8–20 and C 1.0–3.5%, with or without up to 6% Co and up to 1% each Ni, V, Mo, Si and Mn, and contg. less than 0.05% each of S and P, are hardened and rendered "stainless" and rustless by heating to 1150–1250° and then cooling at a definite rate corresponding to the rate at which steel in sheet form of about 18 gage cools in water at normal temp. Various details are given for treating spoons or other articles.

Alloys. SIEMENS & HALSKE A.-G. (Bruno Fetkenheuer, inventor). Ger. 515,798, May 16, 1926. A speculum for medical use is made of an alloy contg. Co or Ni 20–60, W or Mo 15–50, Cr 30 and C, Si or B 1–5 parts.

Alloy for armoring alternating current cables. FELTEN & GUILLEAUME CARLSWERK A.-G. Brit. 339,383, Sept. 25, 1929. See Ger. 504,318 (*C. A.* **24**, 5281).

Alloys for sheathing electric cables. VEREINIGTE TELEPHON- UND TELEGRAPHEN FABRIKS-A.-G. CZEIJA, NISSL & Co. Austrian 121,525, Oct. 15, 1930. An alloy contg. Cu 10–50 and Sb 90–50% is fused with so much Pb and, if desired, unalloyed Sb, that a product contg. Pb up to 0.5 and Sb 0.8–1.2% is obtained.

Alloys resistant to acids. SOC. ANON. DES ANCIENS ÉTABLISSEMENTS SKODA A. PLZEN. Fr. 37,433, Sept. 12, 1929. Addn. to 681,578 (*C. A.* **24**, 4254). Alloys of low content of Ti and Si are used.

Alloy for belt conveyors for high-temperature service. WICKWIRE SPENCER STEEL Co. Brit. 338,951, Aug. 26, 1929. Various structural details are given of belts suitable for use up to temps. of about 870° which may be made of an alloy contg. C 0.16–0.21, Cr 17–18, Ni 25–26, Si 2–3 and Fe 55.84–52.76%.

Bearing alloy. EMIL ABEL (to Jacob Neurath). U. S. 1,795,633, March 10. In forming a bearing alloy of Pb, Sb, Sn and Ni in which the Ni is present in the α-form, the Ni content is restricted to less than about 1% and Cu is added in an amt. at least 1.5 times that of the Ni content.

Antifriction alloy and its production. J. E. ENSLÉN and F. STEIN. Hung. 101,303, May 14, 1928. In an antifriction alloy contg. less than 50% Sn harder Sn-Sb-Cu crystals embedded in the eutectic Cu may be partly replaced by one or more metals of the 3rd group. Also graphite or simliar substance can be added in fine dispersion. To the melted Cu or its alloys with the metals of the 3rd group are added first Sn, then Sb and Pb; the liquid mixt. is cooled with stirring; graphite is added; and finally the alloy is solidified.

Aluminum alloys. H. J. GARRARD. Brit. 338,923, May 30, 1929. In the production of an Al alloy contg. Zn and Mg, with or without Bi, a preliminary alloy of part of the Al with the Zn and Mg is added to the remainder of the Al, and the Bi, if used, is subsequently added. Various details of proportions and procedure are given.

Aluminum alloys. O. KAMPS. Brit. 339,469, Nov. 25, 1929. Alloys are formed of Al together with Ni 0.3–1.5, Th 0.05–0.9, Mn 0.4–0.8 and up to 6.8% of a Cu-Ce alloy contg. 90% Cu. The alloy is quenched from 480–535° to room temp. in a BaCl$_2$ bath and reheated to 50–300°.

Protecting aluminum alloys. ALADAR PACZ. Fr. 695,155, Aug. 14, 1929. Al alloys are protected by colored layers obtained by treating the alloys in alk. solns. of chromates or dichromates contg. not more than 0.25% by wt. of dichromates calcd. as $K_2Cr_2O_7$ and at least 1.5% of alk. substance calcd. as Na_2CO_3.

Alloys of iron and aluminum. BRITISH & DOMINIONS FERALLOY, LTD., and J. W. BAMPFYLDE. Brit. 338,688, Oct. 21, 1929. In making or remelting alloys of Fe and Al, fluorspar or SrF_2 is added. Various details and modifications of procedure are described.

Iron alloys. FERRANTI, LTD. Ger. 515,700, July 11, 1925. An elastic alloy suitable for wire for low-frequency windings of telephones consists of Fe 60.5, Ni 25.99, Cr 11.60 W 1.6 and C 0.36%.

Iron alloys hardened by nitridation. H. A. DE FRIES (to Nitralloy, Ltd.). Brit. 338,655, Oct. 9, 1928. Alloys suitable for hardening by nitridation (suitably as described in Brit. 174,580; *C. A.* **16**, 1738) contain Fe together with C 0.05–2, Al 2.1–6% and a total of 0.2–8% of one or more of the elements Si, Mn, Ni, Cr, Cu, Mo, W, V, Ti or Zr (the C content being about one-third the Al content and the Si content not exceeding the Al content).

Acid-resistant iron alloy. V. F. DONAT and K. V. VLADIMIROV. Russ. appl.

31,146, Aug. 9, 1928. An acid-resistant alloy is prepd. from a 70–80% ferrosilicon and a 60–70% ferrochromium and iron scrap proportions to yield about 18% Si and 2–3% Cr in the alloy. Cast iron melted in another furnace is then added to the above alloy.

Iron and its alloys for chemical apparatus. I. G. FARBENIND. A.-G. Fr. 37,362, Aug. 23, 1929. See Brit. 334,926 (*C. A.* **25**, 1213).

Copper alloys. G. H. WHITEMAN and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 338,676, Oct. 14, 1929. Alloys suitable for tubes contain Cu together with Ni 30 and 4% or less (suitably 2.5%) of Cr. Some mention is also made of the use of larger proportions of Cr.

Copper-aluminum alloys. ALADAR PACZ. Ger. 515,805, Dec 4, 1927. See Brit. 318,802 (*C. A.* **24**, 2421).

Lead alloys for bearings, etc. METALLGES. A.-G. Ger. 518,395, May 19, 1927. Li 0.03–0.05, Na 0.58–0.66, Ca 0.65–0.73, and Al less than 0.2%, the remainder being Pb.

Acetylene. I. G. FARBENIND. A.-G. Ger. 515,916, Aug. 12, 1927. C_2H_2 for autogenous welding is stored and shipped in pressed solid form.

Autogenous welding. I. F. KUBARZHEVSKII. Russ. appl. 49,743, June 21, 1929. An explosive gas mixt. is admitted into the burner simultaneously with acetylene.

Welding composition. JOHN A. HEALY. U. S. 1,796,329, March 17. A compn suitable for use in welding cutting tips to shanks comprises fused borax 30, ferro-Mn 60, ferro-Si 10 parts, together with high-speed steel filings.

Solder. WILHELM REUSS. Fr. 37,159, June 28, 1929. Addn. to 645,549 (*C. A.* **23**, 1866). The solder described in the prior case is used for soldering steel, Fe, Cu, etc.

Treating flux-cored solder. PERRY C. RIPLEY (to Kester Solder Co.). U. S. 1,796,163, March 10. To prevent leakage of flux in storage, solder having a liquid flux core is subjected to a temp. higher than that to which the solder will normally be exposed prior to actual use, to effect an expansion of the liquid flux, and the ends of a strand of the solder are sealed while the liquid flux is in the expanded condition. App is described.

Soldering flux. DANA W. BOWERS (49% to Charles T. Asbury). U. S. 1,797,124, March 17. Beeswax 6–10, oleic acid 25–40 and Ag oxide 1–3 parts are used with a quantity of finely granulated solder about equal to the other ingredients.

Electrical resistance heating device suitable for use in soldering irons, pipes, etc. EDWIN L. WIEGAND. U. S. 1,795,628, March 10. Structural features.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Recent advances in science: organic chemistry. J. N. E. DAY. *Science Progress* 25, 389-92(1931).—A review is given of recent work in org. chem. J. S. H.

Oxidation of methane. I. The homogeneous oxidation of methane under ordinary pressure. KIYOSHI YOSHIKAWA. *Bull. Inst. Phys. Chem. Research* (Tokyo) **10**, No. 3, 251-5(1931)(*Abstracts* 30-1(in English), *published with Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, Nos. 289-91).—CH_4 is oxidized in the presence of air at 600° to CO, CO_2, CH_2O and HCO_2H. At 700° H_2 is formed. HNO_3 promotes the start of the reaction to 500°, yielding more CH_2O. $PbEt_4$ has the opposite effect. The reaction is a homogeneous gas reaction of the chain type. ALFRED BURGER

The reaction of methane and lower homologs with carbon monoxide and dioxide at various catalysts. FRANZ FISCHER AND HERBERT BAHR. *Ges. Abhandl. Kenntnis Kohle* **8**, 279-81; *Chem. Zentr.* **1930**, I, 31.—A repetition of Berthelot's expt., in which C_4H_8 was formed on conducting 1 vol. CO and 2 vols. CH_4 through a glowing glass tube filled with pumice, yielded the same phenomenon. It was impossible to identify the hydrocarbon on account of the small quantity obtained. In another expt. F. and B. conducted the same mixt. of CH_4 and CO over various catalysts at different temps. CO was decompd. with formation of CO_2, and CH_4 dissocd. partly into C and H, but a reaction between CH_4 and CO was scarcely detectable. When the waste gas from a catalyst for the synthesis of mineral oil was conducted over metallic sponge Fe at 900°, the greatest part of the CO_2 was reduced to CO; gasol, heavy hydrocarbons and a fraction of H disappeared, and a large quantity of water was formed. G. SCHWOCH

The decomposition of methane at various temperatures at various catalysts. FRANZ FISCHER AND HERBERT BAHR. *Ges. Abhandl. Kenntnis Kohle* **8**, 27–94; *Chem. Zentr.* **1930**, I, 31.—When a gas mixt. rich in CH_4 (natural gas from Altengamme with 92.5% CH_4) was conducted through a heated quartz tube or through a heated porcelain

tube which was empty or filled with porcelain fragments, the decompn. started at 850° with deposition of C on the tube walls and with the formation of H, tar mist and a slight quantity of small $C_{10}H_8$ crystals. When moist CH_4 is employed, the quantity of the H formed is almost twice that with dry CH_4 (34.3:19.1%). With finely distributed graphite as a catalyst no tar and only very little $C_{10}H_8$ is formed. With $BaSO_4$ as a catalyst H_2O and H_2S are formed at 630–650°; in this case also traces of an unsatd. hydrocarbon were noticed. The latter was also obtained when BaO was used. CH_4 is also decompd. when its presence in the gas current amounts to only 15%; in this case traces of C_6H_6 were noticed, which was identified as $PhNO_2$. When ZnO with addn. of 1% K_2O in the form of K_2CO_3 was used, the CH_4 decompn. began at 700°; at 850° the increase in vol. of the gas was 50.9% and remained the same when the velocity of the current was reduced from 2–5 l. per hr. to 0.5 l. per hr., but it was considerably lessened when the velocity of the current was increased to 6 l. per hr. G. SCHWOCH

The synthesis and spectrochemistry of normal alkanes. A. KARVONEN. *Acta Chem. Fennica* 3, 101–11(1930)(in German).—Normal pentane (I) and heptane (II) were prepd. synthetically and their optical refraction and dispersion compared with those of naturally occurring I and II. I was prepd. by condensation of HCO_2Et with EtMgBr. The resulting Et_2CHOH was treated with I and red P, and the Et_2CHI formed was treated with HI and Zn dust at 0°. Steam distn., washing with NaOH, and drying with $CaCl_2$ and finally with Na gave 66% I, $b_{758.8}$ 36.3° (cor.). II was prepd. from $C_6H_{13}CHO$ by reduction with HCl and amalgamated Zn. Steam distn., washing with $NaHSO_3$, and drying with Na gave II, b_{741} 96°. II was also prepd. in purer form from HCO_2Et and PrMgBr. The Pr_2CHOH (b. 154°) was converted with I and red P to Pr_2CHI, which was treated with Zn dust and HI in glacial AcOH at 0°. Purification gave II in good yields, b_{761} 98.0–98.2° (cor.). The consts. for I and naturally occurring I from petroleum, resp., were: d_4^{20} 0.62783, 0.6249; n_α^{20} 1.35650, 1.35465; n_D^{20} 1.35828, 1.35638; n_β^{20} 1.36267, 1.36080; n_γ^{20} 1.36630, 1.36440. The consts. for II compared in the same way were: d_4^{20} 0.68480, 0.6842; n_α^{20} 1.38734, 1.38584; n_D^{20} 1.38939, 1.38777; n_β^{20} 1.39416, 1.39251; n_γ^{20} 1.39794, 1.39636. When the mol. and sp. refractions, resp. were compared with the dispersions normal values were obtained which were identical for both natural and synthetic I and II. This offers a means for detg. the purity of alkanes. S. A. KARJALA

Transformation of butylenes into liquid hydrocarbons. A. MAILHE AND RENAUDIE *Compt. rend.* 192, 429–31(1931); cf. *C. A.* 24, 5283; 25, 1795.—1-Butene and methylbutene when passed over silica gel at 700° give CH_4, ethylene hydrocarbons, and aromatic hydrocarbons. 2-Butene gives, besides these, $C_{10}H_8$ and anthracene. J. W.

Preparation of some allyl derivatives. R. BRECKPOT. *Bull. soc. chim. Belg.* 39, 462–9(1930).—Allyl chloride is prepd. with a quant. yield, and in a very short time from allyl formate or allyl alc. and concd. aq. HCl. The presence of water does not harm the reaction. CuCl is used as a catalyst, together with a small quantity of H_2SO_4. Very pure vinylacetonitrile is obtained with almost quant. yield, from allyl chloride and CuCN or from a mixt. of CuCN, concd. aq. HCl and allyl alc., or allyl formate, or both. The reaction is fast. Exptl. directions are given. A. L. HENNE

The couples of stereoisomeric ethylenic normal monochlorobutenes. L. NAVEZ. *Bull. soc. chim. Belg.* 39, 435–43(1930).—This reports the prepn., and sepn. by fractional distn., of the following *new* compds. *trans*-MeClC:CHMe (I), b. 62.4–2.8°, d_4^0 0.9361, d_4^{15} 0.9185, $n_\alpha^{13.4}$ 1.4190, $n_D^{13.4}$ 1.4217, $n_\beta^{13.4}$ 1.4289; *cis*-form (II), b. 66.6–7.0°, d_4^0 0.9420, d_4^{15} 0.9246, $n_\alpha^{13.4}$ 1.4225, $n_D^{13.4}$ 1.4250, $n_\beta^{13.4}$ 1.4326; CH_2:CClCH$_2$Me (III), b. 58.4–8.6°, d_4^0 0.9288, d_4^{15} 0.9107, $n_\alpha^{14.1}$ 1.4138, $n_D^{14.1}$ 1.4166, $n_\beta^{14.1}$ 1.4235; *cis*-ClCH:CHEt (IV), b. 63.4–3.6°, d_4^0 0.9329, d_4^{15} 0.9153, n_α^{15} 1.4168, n_D^{15} 1.4194, n_β^{15} 1.5265, *trans*-form (V), b. 68.0–8.2°, d_4^0 0.9376, d_4^{15} 0.9205, $n_\alpha^{14.6}$ 1.4197, $n_D^{14.6}$ 1.4225, $n_\beta^{14.9}$ 1.4296; CH_2ClCHClEt (VI), b. 124°, d_4^0 1.1382, d_4^{15} 1.1224, d_4^{25} 1.1116, n_α^{15} 1.4450, n_D^{15} 1.4474, n_β^{15} 1.4533; inactive MeCHClCHClMe (VII), b. 115.9°, m. −80.4°, d_4^0 1.333, d_4^{15} 1.1147, d_4^{25} 1.1025, n_α^{15} 1.4420, n_D^{15} 1.4445, n_β^{15} 1.4502; *dl*-MeCHClCHClMe (VIII), b. 119.5, d_4^0 1.1366, d_4^{15} 1.1183, d_4^{25} 1.1051, n_α^{15} 1.4433, n_D^{15} 1.4458, n_β^{15} 1.4517 The azeotropic mixts. formed with abs. alc. are as follows (the last figure indicates the % of chlorobutene by wt.): I, b. 56.8–7.2°, d_4^0 0.9131, d_4^{15} 0.8960, 84.6%; II,

b. 60.0–0.4°, d_4^0 0.9139, d_4^{15} 0.8964, 81.6%; III, b. 53.6–4.0°, d_4^0 0.9119, d_4^{15} 0.8945, 88.5%; IV, b. 57.8—8.2°, d_4^0 0.9121, d_4^{15} 0.8946, 85.2%; V, b. 61.2—1.6°, d_4^0 0.9081, d_4^{15} 0.8912, 79.8%. A. L. HENNE

Aliphatic diazo compounds. II. ALEXANDER SCHÖNBERG AND TH. STOLPP (IN PART WITH J. TSCHOLAKOFF AND E. WILLNER). *Ber.* **63B**, 3102–16(1930); cf. *C. A.* **25**, 931.—CH_2N_2 itself reacts with arylsulfur chlorides like diaryldiazomethanes to give hemimercaptole halides: $CH_2N_2 + RSX = CH_2(SR)X$ (I) or $[CH_2(SR)]X + N_2$ (II). The aromatic hemimercaptole halides form mercaptoles with mercaptans and give "free" radicals with Hg and other heavy metals. In C_6H_6 they react instantaneously with BzOAg to give $R_2C(SR')OBz$; the rapidity of the reaction makes it probable that the structure II must be considered along with I. With H_2O they give the corresponding ketone and mercaptole, probably through the hemimercaptole, $R_2C(SR')OH$. With NH_3 in C_6H_6 they do not give the expected $R_2C(SR')NH_2$ (which is probably an intermediate product) but the mercaptole and ketone imide. It had been found that diaryl thioketones react with 1 mol. of certain inorg. metal compds. and it had been concluded that the products are mol. compds. (*e. g.*, $R_2C{:}S\ldots..HgCl_2$). This investigation has been concluded and the results are reported here because these products are now thought to be complexes and very closely related to the aromatic hemimercaptole halides. • A systematic study of the action of aromatic thioketones on $HgCl_2$, $HgBr_2$, $AgNO_3$ and $AgClO_4$ has shown that reaction takes place in every case, although the products cannot always be obtained in cryst. form, and sometimes, although cryst., they decomp. so rapidly that they cannot be isolated in analytically pure form. The following *complex compds.*, however, were obtained in cryst., analytically pure form: $[R_2C(SHgCl)]Cl$: R = *o*-$MeOC_6H_4$, red; *p*-$MeOC_6H_4$, orange. $[R_2C(SHgBr)]Br$: R = *p*-$MeOC_6H_4$, orange; *p*-$EtOC_6H_4$, orange; 3,4-$MeO(EtO)C_6H_3$, orange. $[O(C_6H_4)_2C(SAg)]ClO_4$, blood-red. $[O(C_6H_4)_2C(SHgCl)]Cl$, orange. The color of these compds. is in every case lighter than that of the thioketones from which they are derived, probably because of the disappearance of the C:S group. Some of the compds. are quantitatively converted into the thioketones by covering them with Et_2O and shaking out with aq. KI; this is explained by assuming in the Et_2O phase the equil. thioketone + $HgCl_2 \rightleftharpoons$ complex compd., which is disturbed by the aq. KI. A continuation of the study of the action of diaryldiazomethanes on aromatic disulfides has shown that the formation of mercaptoles in this way is also a general reaction, although it is of significance as a method of prepn. only for asym. mercaptoles which, for some reason or other, cannot be prepd. by other methods, and in connection with the study of the reaction mechanism. *Diazothioxanthene*, $S(C_6H_4)_2CN_2$ (I), was obtained from thioxanthone, $S(C_6H_4)_2CS$ (II), by conversion with N_2H_4 into the hydrazone and oxidation of the latter with HgO or treatment with $S(C_6H_4)_2CCl_2$. Attempts to prep. diazoxanthene (III) in the same way were unsuccessful; the $O(C_6H_4)C{:}NNH_2$ was unchanged by yellow HgO in the cold, and on heating there was obtained the ketazine, $[O(C_6H_4)_2C{:}N]_2$ (IV), the decompn. product of the intermediate III. IV is also obtained from the hydrazone and $O(C_6H_4)_2CCl_2$. Chromone hydrazone could likewise not be converted into the diazo compd. *(o-Nitrophenylmercapto)chloromethane*, from $O_2NC_6H_4SCl$ and CH_2N_2 in Et_2O, yellow, m. around 95°, shows green halochromism with red fluorescence in concd. H_2SO_4, the soln. soon becoming brown. *Diphenyl(o-nitrophenylmercapto)bromomethane*, from $O_2NC_6H_4SBr$ and Ph_2CN_2, red-brown, m. about 108°, fumes in the air (HBr) and gradually becomes smeary. *Diphenyl(p-chloro-o-nitrophenylmercapto)chloromethane*, yellow, m. 121°, evolves HCl on long standing in moist air. *Diphenyl(phenylmercapto)methyl benzoate*, from $Ph_2(PhS)CCl$ and AgOBz in Et_2O, m. 148–9°, shows red-yellow halochromism in concd. H_2SO_4. *Diphenyl(o-nitrophenylmercapto)methyl benzoate* (4.5 g. from 4 g. of the chloride), faintly yellow, m. 132°, shows red-orange halochromism in concd. H_2SO_4. *Diphenylene(phenylmercapto)methyl benzoate* (2 g. from 4 g. $(C_6H_4)_2C(SPh)Cl$), faintly yellow, m. around 132°, shows yellow-brown halochromism with concd. H_2SO_4. *Diphenyl(phenylmercapto)-(o-nitrophenylmercapto)methane* (0.1 g. from 5 g. $O_2NC_6H_4SSPh$ and Ph_2CN_2 refluxed in C_6H_6), yellow, m. 134°. *Di-β-naphthyldiphenylmercaptomethane*, from $(C_{10}H_7)_2CN_2$ and Ph_2S_2, m. 160°, shows deep red halochromism and splits off PhSH in concd. H_2SO_4. The mercaptole could not be isolated from the products of the reaction of (*p*-$MeC_6H_4)_2CN_2$ with Ph_2S_2 and of Ph_2N_2 with (*p*-$MeC_6H_4)_2S_2$ but that it was formed was indicated by the fact that after removal of the ketazine the residual products turned blue at about 210°, and in concd. H_2SO_4 showed halochromism and split off PhSH and MeC_6H_4SH, resp. *Xanthone hydrazone*, from xanthione and $N_2H_4.H_2O$ in abs. alc., light yellow, m. 128–30°, sol. in concd. H_2SO_4 with light yellow color. *Ketazine* (IV), red-yellow,

m. 285°, sol. in concd. H_2SO_4 with orange-yellow color. *Thioxanthone hydrazone*, yellowish, m. 115°, sol. in concd. H_2SO_4 with orange-red color. I, green, m. 105°, sol in ether, petroleum ether and C_6H_6 with violet color and green fluorescence, in H_2SO_4 with orange-red color. *Thioxanthone ketazine*, from the hydrazone with $S(C_6H_4)_2CCl_2$ in C_6H_6, yellow-red, m. 284°, sol. in H_2SO_4 with bright red color. *Chromone hydrazone*, m. 96°, was obtained in 4.5 g. yield from 5 g. chromone with $N_2H_4.H_2O$ in alc. and in 80% yield from 4-thiochromone. C. A. R.

***n*-Butyl ester of phosphoric acid.** A. Arbuzov and I. Arbuzova. *J. Russ Phys.-Chem. Soc.* **62**, 1533–6(1930).—By acting with PCl_3 on BuONa was obtained tri-Bu phosphite, $P(OBu)_3$ (I), identical with the product prepd. by Milobedzki and Sachnowski (*C. A.* **13**, 2865) by the interaction of BuOH, PCl_3 and C_5H_5N. The action of BuI on I gives the isomeric di-Bu butanephosphonate, $BuPO(OBu)_2$, (II), which when sapond. with HCl produces butanephosphonic acid, (III). *Exptl. part.*—First was prepd. BuONa by heating on the water bath 950 g. of freshly distd. *n*-BuOH, b 117°, with 70 g. of metallic Na, then, while cooling, were added Et_2O and PCl_3, the Et_2O was expelled, and the reaction product on distn. gave at 9 mm and 180° (temp. of glycerol bath) 174 g. (68.6%) of crude I. Close fractionation being impossible, the fraction b_7 116–39° (97 g.) was added to 4.5 g. of Na wire suspended in dry Et_2O, then heated 1 hr. on the water bath, poured off from unchanged Na, and redistd., producing 27.6% of I b_8 119.5–20°, d_0^0 0.9309, d_0^{17} 0.9201. In the distg. flask there remained P(OBu)ONa. When 1.28 g. of Br is added to 2 g. of I and then distd. there is obtained 1.83 g. (91.5%) of C_4H_9Br, b. 98°. The isomerization of I to II is effected on heating 8 hrs. at 150–60° in a sealed tube a mixt. of 20 g. of I and 12 g. of freshly distd. BuI (b. 129–31°); the reaction product on redistg. gives 11.80° g. of II, b_{10} 150–51°, d_0^0 0.9634, d_0^{17} 0.9520, colorless and odorless liquid. II is sapond. to III on heating 5 hrs. at 170° in a sealed tube a mixt. of 6.3 g. of II and 2 vols. of HCl (1:1); the upper layer of BuCl, in theoretical yield, was sepd., and the aq. soln. was repeatedly evapd. with H_2O on a water bath, the heavy mass was treated with H_2O, the sepd crystals filtered off, boiled in H_2O with animal charcoal, filtered, and evapd. to dryness; yield of crude III 3.55 g., m. 89–99°; recrystd. from ligroin and dried over H_2SO_4 it m. 101–3°; the acid is dibasic. Chas. Blanc

2-Methyl-2-buten-4-al. F. G. Fischer, L. Ertel and K. Löwenberg *Ber* **64B**, 30–4(1931); cf. *C. A.* **24**, 595.—In connection with the building up of terpene-like substances with open and closed chains it was of interest to prep. and characterize *2-methyl-2-buten-4-al* (I). In a note on the rearrangement of tertiary acetylenecarbinols with HCO_2H, Rupe and Kambli (*C. A.* **20**, 3443) state that dimethylethinylcarbinol gives in poor yield "isopropylidenacetaldehyde" (I), the m. p. of whose semicarbazone is given as 244° in Engl. pat. 267,954. In agreement with them, the authors find that this method is ill adapted to the prepn. of I; after short heating of the carbinol with HCO_2H there is obtained a small amount of a C:O compd. whose semicarbazone, however, m. 221–2° and *p*-nitrophenylhydrazone m. 161–2°. After other methods of prepg. I from Me_2CO had failed, the following method was devised: iso-AmOH ⟶ Me_2CHCH_2CHO ⟶ $Me_2CHCHBrCH(OEt)_2$ (II) ⟶ Me_2C:CH-$CH(OEt)_2$ ⟶ Me_2C:CHCHO (I). The use of fermentation amyl alc. as the starting material has the disadvantage that the Me_2CHCH_2CHO is accompanied by the isomeric EtCHMeCHO, which, however, is removed in the last step of the above reaction, it is probably present as $EtC(:CH_2)CHO$ in the first runnings of the fractionated crude I. The C_4H_8CHO, b. 90–2°, $[\alpha]_D^{29}$ 5.5° (and therefore contg. about 75% Me_2CHCH_2-CHO) in $CHCl_3$ at —25° slowly treated with Br in the light of an Osram lamp and then with abs. EtOH gave 75% of the II, b_{13} 88–9°, d_4^{20} 1.1772, n_D^{20} 1.4489, which, heated 4 hrs. in N with fused KOH, yielded 65–70% of the *methylbutenal di-Et acetal*, b_{13} 163–5°, d_4^{20} 0.8555, n_D^{20} 1.4201, decolorizes only about 0.1 of the calcd. amt. of Br in $CHCl_3$, a slight excess quickly giving a dark green color changing to blood-red on addn. of NaOH; Br water is also decolorized but without the play of colors; anhyd $(CO_2H)_2$ gives a grass-green color and changes the acetal into a viscous liquid converted by heating into a brittle amber-like resin insol. in the ordinary org. solvents but swelling markedly under C_6H_6. Hydrolysis of 53 g. of the acetal with cold satd aq. tartaric acid gives 5 g. b_{60} 26–8°, b. 77–80°, of an unsatd. aldehyde, probably $EtC(:CH_2)CHO$ (*semicarbazone*, m. 183–4°; *p-nitrophenylhydrazone*, golden yellow, m. 141–2°), and 18 g. of I, b_{60} 62–3°, b_{730} 132–3°, d_4^{20} 0.8722, n_D^{20} 1.4526, is easily autoxidizable but stable for a long time in sealed vessels; *semicarbazone*, m. 221–2°; *p-nitrophenylhydrazone*, violet-red, m. 161–2°. Hydrogenation of I with Pd-$CaCO_3$

gives Me_2CHCH_2CHO (semicarbazone, m. 126–7°; *p*-nitrophenylhydrazone, m. 116°). C. A. R.

Absorption and reactivity of the ketone group. Mme. Ramart-Lucas and Mme. Bruzau. *Compt. rend.* **192**, 427–9(1931).—Variations in the chem. activity of the hexaalkyl-substituted ketones can be explained by the rate of absorption of ultra-violet light. This is due to a mutual influence between the alkyl radicals present and the ketone group. Julius White

Catalytic hydrogenation of azines. V. Hydrogenation of ketazines. Determination of affinity capacities of methyl and ethyl groups. K. A. Taipale and P. V. Usachev. *J. Russ. Phys.-Chem. Soc.* **62**, 1241–58(1930); cf. *C. A.* **20**, 3282.—The speed of the reaction of catalytic hydrogenation of aldazines makes possible an estimation of the relative consumption of affinity by various radicals at the C atom in the azimethylene grouping of aldazines (*C. A.* **19**, 3478). If the affinity capacity of the Me group is 100, the relative values of the affinity capacity of hydrocarbon radicals and the H atom for this C atom can be deduced, as follows: H 12, Me 100, Et 135, Pr 200, iso-Pr 555, iso-Bu 700, Ph 600. Other investigators, detg. the affinity capacity of radicals in relation to C, found that the Me group absorbs a greater amt. of affinity than the Et group. Therefore it is desirable to compare the affinity capacities of Me and Et groups in another example than that previously obtained by hydrogenation of the aldazines of AcH and PrH. The following ketazines are considered: bis(dimethyl)azimethylene, $Me_2C{:}NN{:}CMe_2$ (I), bis(methylethyl)azimethylene, (II), bis(diethyl)azimethylene, (III). From the speed of hydrogenation of I and II, and of II and III, we are able to study the different influences of Me and Et groups on the speed of addn. of H to the azimethylene group $>C{:}NN{:}C<$, and from that of I and III the difference in the influence of 2 Me and 2 Et groups, the resulting relations of speeds of hydrogenation enabling us to make an estimate of the relative values of affinity capacities of these 2 radicals. The expts. show that the speeds of hydrogenation of II and I in the presence of Pt black are to each other as 1 to 1.3, those of III and II as 1 to 1.7, and those of III and I as 1 to 2.6; *i. e.*, an azimethylene group joined with Et groups combines with H less readily than the one joined with Me groups. Considering that the speed of hydrogenation of a double bond depends on the magnitude of the residual affinity of the atoms constituting this bond, and that the magnitude of the residual affinity in turn depends on the degree of consumption of the affinity by the radicals combined with these atoms, the conclusion is made that the Et group possesses a higher affinity capacity than the Me group. Having previously assumed the affinity capacity of Me as 100, that of Et then is 140, which corresponds with the value of 135 derived from the speeds of hydrogenation of the aldazines (cf. Kindler, *C. A.* **21**, 1453). The catalytic hydrogenation of ketazines led also to investigation of the properties of the fatty hydrazo compds. formed in the reaction. The properties of hydrazo compds. depend on the size and structure of the radicals attached to the hydrazo group, which influence its reactivity, and are noticeable in their basicity, the reactivity of the H of the imino group, and, probably, in the stability of the hydrazo grouping against decompn. into amines by further addn. of H. T. (*C. A.* **18**, 3049) has shown that $(NHCHMe_2)_2$, obtained by hydrogenation of I, possesses a considerably lower basicity than $(NHMe)_2$, $(NHEt)_2$, $(NHPr)_2$ and $(NHCH_2CHMe_2)_2$. The $(NHCHMe_2)_2$ forms a di-HCl salt, which, however, easily loses 1 HCl; moreover, only the H of 1 imino group is capable of reacting, giving mononitro-, mono-Bz derivs. and the corresponding derivs. of $(NH_2)_2CO$ and $(NH_2)_2CS$, while the other above named hydrazo compds. give disubstituted derivs. Hydrazo-α-methylpropane (IV) and hydrazo-α-ethylpropane (V) obtained, resp., from II and III, behave also like $(NHCHMe_2)_2$. Their di-HCl salts are even less stable: the stability decreasing with the increasing wt. of the radicals. The more affinity is consumed by the radicals from the hydrazo group, the less of the residual affinity remains with the latter, the lower it seems, is its basicity, and also the lower is the stability possessed by the HCl salts. The hydrazines also form only mono-substitution products with BzCl and PhNCS. IV and V and their homologs are very readily oxidized in the air, forming azo compds., which are isomerized with acids and alkalies to hydrazones, and the latter are decompd. with acids into ketones and primary hydrazines. The hydrogenation of ketazines in Ac_2O proceeds differently than in other solvents. After addn. of 1 mol. of H as in the case of AcOH, the addn. of the next mol. of H is very slow. This is explained from a study of the hydrogenation of II, by assuming that the azo compd formed in the first phase of the reaction is isomerized to the hydrazone, which is readily acetylated, and the Ac deriv. of the hydrazone under the influence of the Ac group is more difficultly hydrogenated than the free hydrazone or the azo compd. (Skita and Rolfes, *C. A.* **14**, 3667). *Exptl. part.*—The ketazines were prepd. by the known

methods (K. and C., *C. A.* **15**, 2879). I b_{761} 131–3°, b_{16} 38°, d_4^{20} 0.8389, n_D^{20} 1.45318, calcd. MR_D 36.11, found MR_D 36.16. II b_{760} 171–2°, b_{10} 72°, d_4^{20} 0.8404, n_D^{20} 1.4511, calcd. MR_D 45.35, found MR_D 45.27. III b_{758} 196–7°, b_{37} 110.5–11°, b_{11} 82°, d_4^{20} 0.8419, n_D^{20} 1.4574, calcd. MR_D 54.58, found MR_D 54.44. For the method of hydrogenation see *C. A.* **20**, 3282. Results of hydrogenation: I adds H 1.3 times more readily than II, II 1.5 times more readily than III. The products of hydrogenation of the ketazines were isolated from alc. either by drying the filtrate with K_2CO_3 and then redistg. in H, or by satg. the filtrate with HCl, whereby 60–70% of the mono-HCl salt of the hydrazine is pptd. The mother liquor evapd. *in vacuo* deposits the di-HCl salt contaminated with amino-HCl. The hydrogenation in AcOH produces a 100% yield with no formation of amines (*C. A.* **17**, 3015). IV b_{760} 168.5–9°, b_{11} 100–1°, d_0^0 0.8214, d_4^0 0.8050, n_D^{20} 1.4283, calcd. MR_D 46.28, found MR_D 46.05. The di-HCl salt, loses 1 HCl in the air or H_2O, giving the mono-HCl salt, m. 147°. Diisobutylsemicarbazide, $NH_2CON(C_4H_9)NH(C_4H_9)$, obtained by the action of 1.5 mols. of concd. KCN on 1 mol. of the HCl salt, m. 48–9°. Diisobutyl-4-phenylthiosemicarbazide, $PhNHCSN(C_4H_9)NHC_4H_9$, prepd. by mixing 1 mol. of the base with 1 (or 2) mols. of PhNCS, evapg. and filtering, m. 78–8.5°. Azo-α-methylpropane (VI) was prepd. by adding the calcd. amt. of HgO to 7.5 g. of IV in Et_2O, while cooling; after 24 hrs.' standing the mass was heated on the water bath, filtered, dried with BaO, the Et_2O expelled and redistd., yielding 5.2 g. (70%), b_{758} 140–1°. It is also prepd. by adding 3.5 g. of $NaNO_2$ in H_2O to 6 g. of the HCl salt of IV in H_2O, then a few drops of AcOH is added, allowed to stand 24 hrs., neutralized with Na_2CO_3, extd. with Et_2O, dried with K_2CO_3, b_8 31°, d_0^0 0.7904, d_4^{20} 0.7748, d_{20}^{20} 0.7757, n_D^{20} 1.4127, MR_D (calcd.) 45.81, MR_D (found) 45.72. The isomerization of VI to the hydrazone was carried out by refluxing 3 hrs. with NaOH, fractionating, taking up the part b. 155–64° in Et_2O and satg. with HCl, giving about 50% of isobutylhydrazine-2 HCl, which heated *in vacuo* at 50° goes over to the mono-HCl salt. Dibenzoylisobutylhydrazine, $C_4H_9N_2(BZ)_2$, prepd. by refluxing several hrs. on the water bath a mixt. of 3 g. of VI in C_6H_6, 4 g. of BzCl and some calcined Na_2CO_3, m. 169–70°. Isobutylsemicarbazide, $NH_2CO·N(C_4H_9)NH_2$, was obtained by heating in a water bath a mixt. of the hydrazine-HCl with KCN in soln., extg. with C_6H_6, m. 97.5–8°. V, obtained by hydrogenation of III, b_{753} 193–3.5°, d_4^{20} 0.8210, n_D^{20} 1.4388, MR_D (calcd.) 55.51, MR_D (found) 55.16. The di-HCl salt crystallizes with 1 H_2O, the mono-HCl salt is prepd. from the di-HCl salt on warming. Benzoyldiamylhydrazine, AmNBzNHAm, was obtained by heating the mono-HCl salt of the base with BzCl and dry Na_2CO_3 in C_6H_6, b_{18} 184–5°. Diamylsemicarbazide, $NH_2CONAmNHAm$, prepd. by the action of KCN on the HCl salt of the base, m. 57–57.5°. Azo-α-ethylpropane, obtained by oxidation of the hydrazo compd. with HgO in Et_2O, b_{755} 182°, b_{13} 70°. Amylhydrazine-2 HCl, $Et_2CH·NHNH_2.2HCl$, was obtained by the action of HCl on the azo compd. or hydrazone in Et_2O; the mono-HCl salt is formed on heating the di-HCl salt at 60–70°. Dibenzoylamylhydrazine, $Et_2CHNH_2Bz_2$, prepd. by heating the azo compd. in Et_2O with an excess of BzCl, m. 199.5–200°. Amylsemicarbazide, $NH_2CONAmNH_2$, prepd. from a concd. soln. of HCl salt of the primary hydrazine on heating with an excess of KCN, m. 107–8°.

CHAS. BLANC

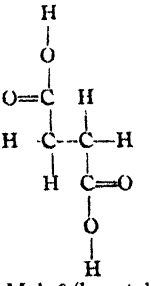
A few derivatives of propylene glycol. A. DEWAEL. *Bull. soc. chim. Belg.* **39**, 395–401(1930).—The following *new* compds. have been prepd. $CH_2ClCH(OMe)Me$, obtained by methylation of $CH_2ClCH(OH)Me$ (I) with Me_2SO_4, b. 103–4°, d_4^{20} 1.009, n_D^{20} 1.41372. $CH_2ClCH(OEt)Me$, prepd. by ethylation of I with Et_2SO_4, b. 117°, d_4^{20} 0.9965, n_D^{20} 1.41902. The dehydration of I by H_2SO_4 gives $(CH_2ClCHMe)_2O$ b_{761} 187–8°, d_4^{20} 1.103, n_D^{20} 1.45046, which reacts with KOAc and HOAc to give $(CHMeCH_2OAc)_2O$, b_{761} 248°, d_4^{20} 1.050, n_D^{20} 1.42654. $EtOCH_2CH(OH)Me$, obtained from alc. and propylene oxide with 2 drops of H_2SO_4, b. 136°, d_4^{20} 0.9028, n_D^{20} 1.4. $EtOCH_2CHMeOAc$ b. 158–60°, d_4^{20} 0.9461, n_D^{20} 1.40968. $CH_2(OH)CH(OEt)Me$, obtained from I through the acetin, b_{761} 140–1°, d_4^{20} 0.9044, n_D^{20}. $CH_2(OMe)CH(OH)Me$ b. 126–7°, d_4^{20} 0.9260, n_D^{20} 1.40696, is obtained from MeOH and propylene oxide, with H_2SO_4. $MeOCH_2CH(OAc)Me$ b_{761} 147°, d_4^{20} 0.9709, n_D^{20} 1.40449. $Me_2CHOCH_2CH(OH)Me$, b_{765} 142–3°, d_4^{20} 0.9059. The condensation of $HOCH_2CHClMe$ and propylene oxide with H_2SO_4 gives $MeCHClCH_2OCH_2CH(OH)Me$, b_{762} 204–5°, d_4^{20} 1.059. $CH_2(OCOPr)CHClMe$ b_{761} 184°, d_4^{20} 1.031, n_D^{20} 1.42875. $AcOCH_2CH(OAc)Me$

b_{758} 190–1°, d_D^{20} 1.059, n_D^{20} 1.4173, treated with HCl gives a mixt. of $ClCH_2CH(OH)Me$ (preponderant) and $CH_2(OH)CHClMe$ while HBr gives a mixt. of the 2 corresponding Br derivs. A. L. HENNE

Ether-like compounds. III. Polyether acids of the type $R.O.(CH_2.CH_2.O)_n.CH_2CO_2H$. M. H. PALOMAA AND T. A. SITONEN. *Ber.* 63B, 3117–20(1930); cf. *C. A.* 13, 2863.—The mono- and di-ether acids of the above type (n = 1 and 2) are readily obtained by converting the com. "alkylglycols" and "alkylpolyglycols" into the corresponding Na alcoholates, adding $ClCH_2CO_2H$ and liberating the acids from the resulting Na salts. The Na alcoholates are very sol. in ether or the corresponding ether alc. and on evapn. of the solvent yield crystals which have not yet been investigated. The poly-ether acids are also relatively easily sol. in H_2O and their extn. (especially of the MeO derivs.) from H_2O with ether is a time-consuming operation. The MeO compds. exchange the Me for H with HI. *(β-Methoxyethoxy)acetic acid* (yield, 80%, based on the $ClCH_2CO_2H$), thick oil miscible with water in all proportions, b_4 121-2°, d_D^{20} 1.1634, n 1.43375, 1.43592, 1.44129, 1.44556 at 20° for α, D, β and γ; *Et ester*, from the acid in abs. alc. with $CuSO_4$ and a few drops concd. H_2SO_4, miscible with water in all proportions, b_{10} 90°, d_4^{20} 1.0369, n 1.41697, 1.41908, 1.42412, 1.42836. *(β-Ethoxyethoxy)acetic acid*, b_4 125–6°, d_4^{20} 1.1103, n 1.43349, 1.43572, 1.44100, 1.44534. *(β-Propoxyethoxy)acetic acid* (from *ethylenglycol mono-Pr ether*, b. 150–0.5°, d_4^{20} 0.9106), b_4 131°, d_4^{20} 1.07415, n 1.43432, 1.43652, 1.44186, 1.44604. *(β-Butoxyethoxy)acetic acid* (from redistd. com. "butylglycol," b_{758} 168–9°, b_4 50°, d_4^{20} 0.9015, n 1.41711, 1.41980, 1.42493, 1.42901), miscible with water, b_6 141°, d_4^{20} 1.04635, n 1.43605, 1.43823, 1.44360, 1.44797. Repeatedly refractionated $MeOCH_2CH_2OCH_2CH_2OH$ (com. "methyl polyglycol"), b_4 65°, d_4^{20} 1.02695, 1.42475, 1.42686, 1.43197, 1.43620, gave *[β-(β'-methoxyethoxy)ethoxy]acetic acid*, miscible with water, b_4 155–6°, d_4^{20} 1.1492, n 1.44351, 1.44575, 1.45112, 1.45553. C. A. R.

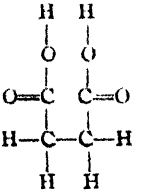
Itaconic anhydride and itaconic acid. R. L. SHRINER, S. G. FORD AND L. J. ROLL. *Org. Syntheses* 11, 70–2(1931).—Heating citric acid until it melts and then rapidly distg. gives 37–47% of itaconic anhydride; the free acid is obtained by refluxing with H_2O for 1 hr. C. J. WEST

Resolution of synthetically prepared isoleucine into its four optically active components, namely *l*- and *d*-isoleucine and *d*- and *l*-alloisoleucine. EMIL ABDERHALDEN AND WALTHER ZEISSET. *Z. physiol. Chem.* 195, 121–31(1931).—Isoleucine, $EtCHMeCH(NH_2)CO_2H$, contains 2 asym. carbons, and its synthetic prepn. should therefore consist of 2 pairs of optical isomers. The 2nd pair has hitherto been overlooked. Isoleucine was prepd. by the previously described method (*C. A.* 4, 172) in which $EtCHMeCHBrCO_2H$ is aminated with NH_4OH. The sepn. of the isomeric pairs was effected by repeated pptn. of the aq. soln. by EtOH in which *dl*-isoleucine is insol., and recovery of *dl*-alloleucine from the mother liquor by distn. of the Et ester and sapon. of the distillate by boiling with H_2O. Sepn. of the optical isomers was effected by converting the *dl*-mixt. into the formyl deriv. and crystg. the brucine salt of the latter. The properties of the 4 individual isomers and their HCO, $PhSO_2$, PhNCO and α-$C_{10}H_7NCO$ derivs. are described. *l-Isoleucine* m. 285–6 (decompn.), $[\alpha]_D^{20}$ in H_2O 30.7°, in 20% HCl 40.8°; *l-alloisoleucine* m. 278° (decompn.), $[\alpha]_D^{20}$ in H_2O 14.0°, in 20% HCl 38.1°; *d-isoleucine*, m. 283–4° (decompn.), $[\alpha]_D^{20}$ in H_2O —10.7°, in 20% HCl —41.6°; *d-alloisoleucine*, m. 274–5° (decompn.), $[\alpha]_D^{20}$ in H_2O —14.2°, in 20% HCl —38.0°; *formyl-l-isoleucine*, m. 155°, $[\alpha]_D^{20}$ in EtOH 26.6°; *formyl-l-alloisoleucine* m. 126°, $[\alpha]_D^{20}$ in EtOH 24.2°; *formyl-d-isoleucine*, m. 156°, $[\alpha]_D^{20}$ in EtOH —26.8°; *formyl-d-alloisoleucine*, m. 126°, $[\alpha]_D^{20}$ in EtOH —25.2°; *benzenesulfonyl-l-isoleucine* m. 153°, $[\alpha]_D^{20}$ in *N* NaOH —14.4°, in EtOH 25.3°; *benzenesulfonyl-l-alloisoleucine*, m. 147-8°, $[\alpha]_D^{20}$ in EtOH 30.7°; *benzenesulfonyl-d-isoleucine*, m. 153–4°, $[\alpha]_D^{20}$ in *N* NaOH 14.3°, in EtOH —25.5°; *benzenesulfonyl-d-alloisoleucine*, m. 147–8°, $[\alpha]_D^{20}$ in EtOH —30.7°; *l-isoleucine phenyl isocyanate deriv.*, m. 121°, $[\alpha]_D^{20}$ in *N* NaOH 14.9°, in EtOH 37.5°; *l-alloisoleucine phenyl isocyanate deriv.*, m. 151°, $[\alpha]_D^{20}$ in NaOH 16.9°, in EtOH 30.8°; *d-isoleucine phenyl isocyanate deriv.*, m. 119–21°, $[\alpha]_D^{20}$ in NaOH —15.0°, in EtOH —36.3°; *d-alloisoleucine phenyl isocyanate deriv.*, m. 151°, $[\alpha]_D^{20}$ in NaOH —16.8°, in EtOH —30.6°; *l-isoleucine α-naphthyl isocyanate deriv.*, m. 178–9°, $[\alpha]_D^{20}$ in EtOH 30.1°; *l-alloisoleucine α-naphthyl isocyanate deriv.*, m. 165–6°, $[\alpha]_D^{20}$



in EtOH 25.1°; *d-isoleucine α-naphthyl isocyanate deriv.*, m. 177–8°, $[\alpha]_D^{20}$ in EtOH —29.5°; *d-alloisoleucine α-naphthyl isocyanate deriv.*, m. 168°, $[\alpha]_D^{20}$ in EtOH —25.5°. *Formyl-dl-isoleucine*, m. 120–1°; *formyl-dl-alloisoleucine*, m. 117–8°; and *dl-alloisoleucine Et ester*, b_{15} 85–8° (7–8° lower than the recorded b. p. of *dl*-isoleucine Et ester).

A. W. Dox



Action of thionyl chloride on some anilic acids. W. H. Warren and R. A. Briggs. *Ber.* **64B**, 26–30(1931).—By the action of PCl_5 on $HO_2CCONHPh$ Aschan obtained $ClCOCONHPh$ which on heating readily lost HCl and CO and yielded about 85% PhNCO. He suggested that oxanil (I) was possibly an intermediate product, but the properties of I are so characteristic that it could not have escaped detection if it had been formed; moreover, it is not affected by PCl_5. In attempting to prep. PhNCO by this method but with $SOCl_2$ instead of PCl_5 W. and B. obtained I instead of PhNCO, and they found that a no. of other anilic acids react in the same way with $SOCl_2$. The anils were obtained by refluxing the anilic acid with 8 parts $SOCl_2$ in an all-glass app. until the evolution of HCl and SO_2 ceased, distg. off the excess of $SOCl_2$, washing with petroleum ether (dried over Na) or C_6H_6, extg. the last traces of anilic acid with boiling H_2O and crystg. from an appropriate solvent. I, crystd. from $PhNO_2$, does not m. 320°, mol. wt. in boiling $PhNO_2$ 154.4, unchanged by most dil. or concd., hot or cold mineral acids but sol. in hot concd. H_2SO_4 with decompn. into $PhNH_2$, CO and CO_2, decompd. by hot NaOH with evolution of a PhNC odor, converted by boiling $Ba(OH)_2$ into $PhNH_2$ and $(CO_2)_2Ba$, by alc. NH_3 in sealed tubes into $(CONHPh)_2$ and $(CONH_2)_2$ and by excess of boiling $PhNH_2$ into $(CONHPh)_2$. *Malonanil*, light yellow, m. 249°, similarly obtained from $HO_2CCH_2CONHPh$, is apparently not affected by concd. HNO_3 or HCl, decompd. by hot concd. H_2SO_4 into $PhNH_2$, CO_2 and AcOH, converted by alc. NH_3 in sealed tubes into $CH_2(CONHPh)_2$ and $CH_2(CONH_2)_2$ and by boiling NaOH into $PhNH_2$ and $CH_2(CO_2Na)_2$. In the same way were prepd. succinanil, m. 156°, *glutaranil*, does not m. 320° (possibly a polymer of Bödtker's compd., m. 144–5°, obtained directly from glutaric acid and $PhNH_2$ (*Diss. Leipzig*, 1891)), phthalanil, m. 203°, camphoranil, m. 116°, and *diphenanil*, m. 199° (*diphenanilic acid*, from diphenic anhydride and $PhNH_2$, m. 176°).

C. A. R.

The polymorphism of the saturated diacids of the aliphatic series as a function of temperature. F. Dupré la Tour. *Compt. rend.* **191**, 1348–50(1930).—Two forms of succinic acid have been studied under the microscope and by x-rays. β-Succinic acid, stable at low temps., is triclinic pinacoidal with *a* 5.04 A. U., *b* 7.58 A. U., *c* 9.75 A. U. At about 137° a transformation to the α-form occurs The α-acid is monoclinic prismatic with *a* 5.03 A. U., *b* 8.75 A. U., *c* 7.48 A. U. The mol. structure appears to be modified thus in the cryst. change:

Mol. β (less stable)

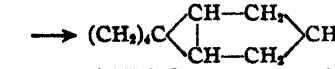
H. W. Walker

Additive heteropolymerization. Theodor Wagner-Jauregg. *Ber.* **63B**, 3213–24 (1930).—In the investigation of highly polymerized org. natural products Staudinger and his pupils have made use of model compds. prepd. by polymerization, or addn. to each other, of several identical mols. of low mol. wt. It is now shown that 2 unlike units of low mol. wt., each contg. a C:C union, can likewise be combined into a large mol. by polymerizing addn. The name *additive heteropolymerization* is suggested for such a process. The present paper deals with the prepn. of addn. heteropolymerizates without the use of catalysts from 2 ethylene components, 1 of which was maleic anhydride (I). I alone shows no tendency to polymerize but has a pronounced additive capacity. When it is boiled with stilbene (II) in xylene, there seps. 45–70% of a white, amorphous, infusible *substance* (III) insol. in most org. solvents, sol. colloidally, with preliminary

swelling, in others (including camphor). Because of its slight soly., its mol. wt. could not be detd., but it is doubtless very high, for the accompanying polymer homologs extd. in very small amount by boiling xylene have in molten camphor an av. particle size of about 4200, corresponding to an av. content of 15 mols. each of I and II. On dry distn. with or without $Ba(OH)_2$ it decomps. with regeneration of II. From its compn. it consists very nearly of equal nos. of I and II mols., irrespective of the relative proportions of the 2 components in the original reaction mixt. (the ratio II:I in the product obtained from a 2:1 mixt. is 1:1, and in that obtained from a 1:2 mixt. it is 0.95:1). The constancy of the stoichiometric compn. would seem to point to a product built up according to a definite plan, such as —$\left[\begin{matrix}\text{CHPh.CHPh.CH}\text{——}\text{CH}\\ \qquad\qquad\qquad\quad\ \ \text{CO.O.CO}\end{matrix}\right]_x$—. A soln. of the product in $(CHCl_2)_2$ absorbed Br only after long boiling and in very small amount. Along with the III there is formed a very small amount (about 10% of the wt. of the III) of very slightly more sol. polymerization products; the rest of the original materials remains unchanged. The polymerization does not take place in the lower-boiling C_6H_6 and PhMe, but there also seems to be a sp. solvent factor, for the yield is much smaller in $(CHCl_2)_2$ which boils about 6° higher than xylene and even less in the molten mixt. at the temp. of boiling xylene. Conversely, benzalfluorene (IV) and I give in good yield in the fused mixt. at 130°, but not in xylene, a white amorphous *heteropolymer* very similar to III, insol. in the fused mixt. of the components; no intermediate products of lower mol. wt. were observed; the ratio IV:I is 1:1 and 0.9:1, resp., in the products obtained from 2:1 and 1:2 mixts. of IV and I. The fused mixt. of anisalfluorene and I at about 130° also deposits an amorphous *polymer*. The *heteropolymers* of $PhCH_2CH_2CH:CHPh$ (V) and I are likewise sol. in the fused mixt. of the nonomers. The ratio V:I is not 1:1 but shifted in favor of I (1:1.5 and 1:1.3–1.25); the V are relatively easily sol. Attempts to prep. heteropolymerizates of bromostilbene, $Ph_2C:CPh_2$, $(PhCH_2CH:)_2$ and other unsatd. compds. with I were unsuccessful, indicating that the nature of the substituents on the C:C union has an influence on the tendency to heteropolymerization. Steric influences also play a role, for isostilbene with I gave a polymer in only very poor yield. While the hydrocarbons which are well adapted to heteropolymerization show no marked tendency to homopolymerization, the easily polymerized $Ph_2C:CH_2$ forms with 2 mols. I a well crystd. *compd.* (VI) having the calcd. mol. wt. 376. Succinic anhydride cannot be substituted for I in these reactions but $(PhCH_2)_2$ gives, although in very poor yield, a 1:1 heteropolymerizate with I. Amylene and styrene heated with I give viscous, gummy masses. Styrene and di-Me maleate gave a white amorphous powder which, from its compn., contained 4–5 styrene mols. to each ester mol. and gave di-Me fumarate on dry distn. Some substances with a C:N union also seem to form heteropolymerizates with I; I boiled with fluorenone-imine in C_6H_6 or with benzal- or cinnamalazine, in PhMe or xylene gives yellow to brown, amorphous products; benzalazine, in addn., gives a cryst. addn. *product* (VII) contg. 2 mols. I, and, with di-Me maleate in xylene, an analogous product (VIII). VI, $C_{32}H_{16}O_6$, m. 279–81° (cor., decompn.), mol. wt. in camphor 373–8, sol. in hot 2 *N* NaOH and boiling 2 *N* Na_2CO_3, gives a green color with cold alk. $KMnO_4$, decolorizes $KMnO_4$ in Me_2CO only very slowly, does not decolorize Br in boiling AcOH VII, $C_{32}H_{16}O_6N_2$, m. 243–4° (cor.). VIII, $C_{36}H_{28}O_6N_2$, m. 232–4° (cor.). C. A. R.

Glucomannan from "konjak." I. Kitsuji Nishida and Hideo Hatori. *J. Agr. Chem. Soc. Japan* **6**, 991–5; *Bull. Agr. Chem. Soc. Japan* **6**, 78–80(1930).—The mannan was liquefied by boiling with H_2O or by enzymes and pptd. with alc. The mannan still contains the other impurities such as inulin, pectin, galactan, fructan, xylan, araban, etc. The powd. crude mannan was heated with H_2O under 1–1.5 atm. in an autoclave. It was pptd. by Fehling soln. and decompd. by alc. HCl. Pure mannan was pptd. by alc. and Et_2O. It is a white powder which has no I reaction and does not reduce Fehling soln. Its ash content is 0.10–0.45%. II. *J. Agr. Chem. Soc. Japan* **6**, 1065–77; *Bull. Agr. Chem. Soc. Japan* **6**, 80–2(1930).—The mannan was hydrolyzed by mineral acids of various concns. The hydrolysis was complete with 2% HCl after 25 hrs. The ratio of mannose to glucose was 1:1 from the detn. of mannose as the phenylhydrazones and 2:1 by calcn. from the rotation. The difference is due to the incomplete pptn. of mannose phenylhydrazone. When a large amt. of $PhNHNH_2$ was added, the ratio was 2:1. Glucomannan of "konjak" consists of 2 mols. of mannose and 1 mol. of glucose. Y. Kihara



A mannan from the bulb of Lilium. I. Teizo Takahashi. *J. Agr. Chem. Soc. Japan* **6**, 791–9(1930).—The water ext. of the lily bulb powder was filtered and

pptd. with alc. The ppt. was hydrolyzed by dil. HCl. Only mannose and glucose were identified, resp., as phenylhydrazone and osazone in the hydrolyzate. The mannan obtained was named "yurl-mannan." Tri-Ac deriv. is a white powder, sol. in AcOH, CH_2Cl, acetone, AcOEt and pyridine, m. p. about 245°, $[\alpha]_D^{14}$ —17.61°. II. *Ibid* 861–9.—The mannose and glucose ratio is 2:1. The aldose detn. method of Willstätter and Schudel was examd. for mannose, galactose, glucose, fructose, arabinose and xylose. When 3.5–5 times the 0.1 *N* I theoretically required was used, mannose was detd. quant. In "yurl-mannan" no ketose is present. Y. KIHARA

The dispersion of the refraction of cyclic hydrocarbons. MARCEL GODCHOT AND (MLLE.) G. CAUQUIL. *Compt. rend.* 191, 1326–8(1930).—From $n_D^{13.5}$ and $n_\alpha^{13.5}$ and $d_{13.5}$ the sp. dispersion $\Delta n/d$ has been calcd. for a no. of satd. and unsatd. cyclic hydrocarbons of C_6, C_6, C_7 and C_8. Δn increases with increasing mol. wt. and the value for the unsatd. compds. is more than 20 units greater than that for the corresponding satd. compd. $\Delta n/d$ has the nearly const. value of 124×10^{-4} for the satd. compds. and 151×10^{-4} for the unsatd. compds. It is independent of the nature of the ring, being the same for methylcyclopentane, cyclohexane and methylcyclooctane and likewise the same for cyclooctene and methylcycloheptene. Aromatic hydrocarbons with $\Delta n/d$ about 250×10^{-4} may be detd. in oils in the presence of cyclic hydrocarbons. H. W. WALKER

Cyclopentylidenecyclopentane and its relation to catalytic hydrogenation. N. D. ZELINSKI AND N. I. SHUIKIN. *J. Russ. Phys.-Chem. Soc.* 62, 1343–54(1930); cf. *C. A.* 25, 1513.—After the failure to obtain 1,1-dihydroxydicyclopentyl (pinacol of cyclopentanone) for the prepn. of spirocyclodecane (*C. A.* 24, 76), the attempts to obtain the pinacol from cyclopentylidenecyclopentane (I) by oxidation with BzO_2H, or to convert I into the glycol with $KMnO_4$, have also met with negative results. The hydrogenation of I in presence of Pt-C produced a satd. hydrocarbon different from the expected dicyclopentyl (II). These 2 negative results have led to an investigation of the starting product, cyclopentylidenecyclopentanone (III). III was prepd. by Wallach's method (*Ber.* 29, 2955(1896)), and by dehydrating cyclopentanone (IV) vapors with Al_2O_3 at 200°. Of interest is a large increment in the mol. refraction of III, while I derived from III shows considerable optical decrement. The high coeff. of refraction of III may indicate that a considerable part of III is present in tautomeric (enol) form The relation of the structures of III and I may be elucidated by decompn. of the hydrazone of III in the presence of Pt, whereby instead of substitution of H_2 for N at the C bearing O, the reaction probably proceeds by way of an intermediate pyrazoline to a tricyclic spiro-hydrocarbon:

1,1-Tetramethylenebicyclohexane (V) reacts with Br and $KMnO_4$ as an unsatd. compd., and with BzO_2H not at all. By catalytic reduction must be formed a satd. hydrocarbon $C_{10}H_{18}$, spirocyclodecane, $(CH_2)_4C(CH_2)_4CH_2$ (VI), which evidently undergoes isomerization to methylspirocyclononane, $(CH_2)_4C.CHMe.CH_2.CH_2.CH_2$ (VII). The phys. properties of V are almost identical with those of IV, and greatly different from those of II. *Exptl. part.*—The prepn. of III from IV with such agents as alc. EtONa (Wallach), solid KOH, alc. KOH, or KCN gives up to 40% of higher condensation by-products, while passing vapors of IV over Al_2O_3 at 200° results in a 41% yield of III with practically no formation of by-products. A mixt. of IV and concd. alc. KOH is allowed to cool, then heated 1.5 hrs. on the water bath, treated with H_2O, the oily layer extd. with Et_2O, dried with solid KOH, the Et_2O expelled, and distd. *in vacuo*, b_{10} 116–8°, n_D^{20} 1.5211, d_4^{20} 1.0172; oxime m. 122–3°; semicarbazone, m. 167–70° (decompn.); hydrazone, m. 88–94° (decompn.). III obtained by heating IV 4 hrs. with 10% solid KCN, n_D^{20} 1.5186, d_4^{20} 1.0172, b_{11} 119–21°, b. 252–4°. The fraction b_{10} 185–200° on recrystn. from EtOH m. 83–4° and analyzes for a compd. to which Wallach ascribes the m. p. 76–7°, and the formula $(CH_2)_4C:C.CO.C:C(CH_2)_4$.

V, obtained by distg. the hydrazone of III in presence of KOH and Pt, treating with dil. AcOH, washing with H_2O to a neutral reaction, drying with K_2CO_3, and twice distg. over metallic Na, colorless liquid, reacting with $KMnO_4$ and Br, $b_{744.5}$ 189–90°, n_D^{17} 1.4864, d_4^{17} 0.9134. V produces with $KMnO$

no pinacol, and does not react with BzO_2H. By passing V 3 times over Pt-C at 190° and subsequently distg. over Na is obtained VII, b_{739} 184–5°, n_D^{19} 1.4708, n_D^{20} 1.4701, d_D^{20} 0.8728, which reacts with $KMnO_4$ very slowly, and on dehydrogenation over Pt-C at 300° shows no change. 1-Cyclopentenylcyclopentane, (VIII), was obtained by dehydrating cyclopentyl-2-cyclopentanol (IX), prepd. by reduction of III with Na in aq. Et_2O. VIII, b_{741} 189–91°, n_D^{20} 1.4853, d_4^{20} 0.8898, reacts with $KMnO_4$ and Br, and when reduced over Pt-C at 190° gives II. Cyclopentyl-2-cyclopentanone (X), obtained when 38 g. of IX is mixed with 80 cc. of 80% AcOH, to which is added 17 g. of CrO_3 in 80 cc. of H_2O, the whole is heated 30 min. on the water bath, dild. with H_2O, the oily layer sepd., washed with H_2O, dried with calcined K_2CO_3, and redistd., b_{10} 111–3°; semicarbazone, m. 210°, d_4^{22} 0.9748, n_D^{22} 1.4793. *Prepn. of* II. The hydrazone was prepd. by heating on the water bath 23 g. of X with 11.5 g. of $N_2H_4.H_2O$ in alc., the crude product was decompd. with KOH in presence of Pt powder, dried with $CaCl_2$ and redistd. over Na, b_{744} 188–89.5°, d_4^{21} 0.8652, n_D^{21} 1.4638. CHAS. BLANC

A hydrocarbon from pine oil essence and the stereoisomeric 1,2-dimethylcyclopentanes. G. CHAVANNE. *Bull. soc. chim. Belg.* 39, 402–11(1930).—A fractional distn. of C_7H_{12}, prepd. by dehydration of 1,2-dimethyl-1-cyclopentanol, gives about 10% of MeC:CMe.CH_2.CH_2.CH_2, b. 96–7°, d_4^{20} 0.783, n_α^{20} 1.4321, n_β^{20} 1.4415, n_γ 1.4472, n_{H_α} 1.4349, m. —124.8°, and 90% of HC:CMe.CHMeCH_2.CH_2, b. 105.0–5.2°, d_4^{20} 0.7952, d_4^{15} 0.7998, n_α^{20} 1.4412, n_β^{20} 1.4511, n_γ^{20} 1.4571, n_{H_α} 1.4442, viscosity η_{15} 0.00537, m. —90.4°. These synthetic hydrocarbons are compared with C_7H_{12} from pine oil, and it is concluded that the natural product is probably the isomer b. 105°, with a small amount of impurity which affects its d. and n, but not its b. p. The hydrogenation of C_7H_{12} with Pt black gives the 2 stereoisomeric forms of 1,2-dimethylcyclopentane, one of which b. 91.8° ± 0.1°, b_{741} 90.95°, d_4^{20} 0.7495, d_4^{15} 0.7541, m. 120°, n_α^{20} 1.4093, n_β^{20} 1.41659, n_γ^{20} 1.42077, $n_{H_\alpha}^{20}$ 1.41155, while the other b. 99.25 ± 0.1°, b_{741} 98.40°, m. —62°, d_4^{20} 0.7718, d_4^{15} 0.7764, n_α^{20} 1.42014, n_β^{20} 1.42748, n_γ^{20} 1.43180, $n_{H_\alpha}^{20}$ 1.42202. The spatial configuration is discussed. A. L. HENNE

β-Enines and β-diines. V. GRIGNARD AND L. LAPAYRE. *Compt. rend.* 192, 250–3(1931).—The influence of 2 triple bonds; or 1 triple and 1 double bond, in the β-position, on the acidity of the central CH_2 group was investigated. For this purpose the reactions of *1,5-diphenyl-1,4-pentadiine* PhC:CCH_2C:CPh (I), *1-phenylpent-4-en-1-ine*, PhC:CCH_2C:CH_2 (II), and *dec-1-en-4-ine* Me$(CH_2)_4$C:CCH_2CH:CH_2 (III) with Na, $NaNH_2$, EtMgBr were studied. By heating I with EtMgBr, 1 mol. of C_2H_6 is evolved at 35°, 2 mols. at 70°. II and III show monoacidity at 70°, III does not evolve 2 complete mol. equivs. of C_2H_6 at 175°. $NaNH_2$ evolves more than one NH_3 from I and III, in consequence of a partial rearrangement to derivs. of C_2H_2 with free active H. The triple bond exerts a more negativating effect on the CH_2 group in these systems than the double bond; the aromatic substituents reënforce this action. I, prepd. from CH_2I_2 and Mg phenylacetylide (IV), m. 88–90°; yield 8%. Allyl bromide (V) and IV yield 70% of II, a liquid, b_{20} 103–5°, d_{16}^{16} 0.940, n_D^{18} 1.558, exaltation of the mol. refraction 1.9. Mg pentylacetylide and V yield III, a liquid b_{18-20} 82–5°, d_{11}^{11} 0.806, n_D^{16} 1.459, exaltation 0.4. It becomes resinous on standing. ALFRED BURGER

Sulfides and polysulfides of organic bases. T. G. LEVI. *Gazz. chim. ital.* 60, 975–87(1930).—A review of the literature shows a great scarcity of expts. on the prepn. of polysulfides of org. bases. In view of this, several polysulfides were prepd. and their properties studied. Phenylbiguanide-H_2S (I) was prepd. by the method of Romani (cf. *C. A.* 18, 1066), and its analysis, not undertaken by R., confirmed its compn. Phenylbiguanide sulfide could not be obtained as indicated by R. (who did not analyze it), *i. e.*, by slow conversion of I in air, or rapid conversion on heating, with loss of H_2S; and even by the action of concd. aq. $(NH_4)_2S$ on phenylbiguanide only I is formed, and on the other hand when aq. I is heated gently, H_2S is eliminated, but no neutral sulfide is formed. All attempts at the prepn. of diphenylguanidine sulfide were without success. Alc. *o*-tolylbiguanide treated with H_2S, and Et_2O added, ppts. in good yield *o-tolylbiguanidine hydrosulfide* $C_9H_{12}N_5.H_2S$, m. 123–6°, stable at room temp. when kept dry, decomps. slowly in cold water. Benzylamine polysulfide, $(PhCH_2NH_2)_2.H_2S_6$ (II), was prepd. in a different way from that described by Bruni and Borgo (cf. *C. A.* 2, 2058). Addn. of S to $PhCH_2NH_2$ (III) gives the orange color characteristic of poly-

sulfides; if at the same time H_2S is passed in, there is an abundant ppt. of II, but it is so unstable that it cannot be washed and dried to const. wt. without loss of H_2S. When dil. aq. III-HCl is poured into excess NH_4 polysulfide (approx. compn. $(NH_4)_2S_{3.6}$ prepd. from NH_4OH of d. 0.92), II is pptd. and under these conditions it is more stable, and it can be washed with water without losing H_2S, but when it is dried in a desiccator or in air, it decomps. slowly. Since it was impracticable to obtain II dry enough to analyze, it was analyzed in the wet state. This analysis indicated $(PhCH_2NH_2)_2.H_2S_6$. Further attempts to isolate polysulfides of other aliphatic and heterocyclic bases, particularly secondary bases, were unsuccessful, though the formation of the polysulfides was proved. When S is added to $C_5H_{10}NH$ (IV) the liquid turns more intensely orange than with III, and heat is evolved (cf. Bedford, U. S. Pat. 1,719,920 (*C. A.* 23, 4376). To isolate the IV polysulfide (V), the reaction product was washed with Et_2O and with CS_2, but during this it decompd. with evolution of H_2S. The reaction mixt. was therefore extd. with cold water, but the yellow water ext. let stand rapidly became turbid and S sepd. With acids it forms H persulfide, which proves the formation of V. V is readily decompd. by excess PbO, in which case the liquid becomes colorless, and IV probably forms a polythioamine. By filtering off the PbS, spontaneous evapn., soln. in EtOH and partial pptn. with water of the residue from the evapn., the polythiopiperidine seps., and can be purified by recrystn. from EtOH. The reactions are: (1) $2\,IV + xS \longrightarrow (C_5H_{10}N)_2S_{x-1} + H_2S$, and (2) $2\,IV + H_2S + xS \longrightarrow (C_5H_{10}NH)_2.H_2S.S_x$. Data on *N*-polythioamines higher than the dithio derivs. are to be published in a forthcoming paper. Et_2NH and S behave similarly at ordinary temp. With all these bases, attempts to sep. the polysulfides from solns. of salts of the corresponding bases and $(NH_4)_2S_x$ were not successful. The method of Romani (*loc. cit.*) for the prepn. of phenylbiguanide polysulfide, $(C_8H_{11}N_5)_2.H_2S_2$, *viz.* by boiling aq. I with S, was not considered satisfactory, because, as was verified by expt., there is too great a loss of H_2S and sepn. of phenylbiguanide (VI). Accordingly concd. alc. VI contg. S was treated with H_2S, under which conditions a mixt. of I and a polysulfide (VII) pptd., and the latter alone could not be obtained because I is insol. and seps. immediately, and then is transformed slowly and incompletely into VII. In contrast to this, $(PhHN)_2C{:}NH$ does not form directly a sulfide or H_2S deriv., and in general this method of prepn. of polysulfides is of greater advantage where the base forms only the polysulfide. A mixt. of I and VII was also obtained when the starting material was alc. $(NH_4)_2S$. In contrast to this, cold satd. aq. pure (approx. 5%) VI (m. 143°) (100 cc. + 10 cc. addnl. water) and aq. $(NH_4)_2S_5$ (100 cc. prepd. by satg. NH_4OH (100 cc. of d. 0.920) with H_2S, adding 100 cc. more of NH_4OH and heating in the absence of air with 70 g. of S) let stand several days in a sealed vessel, the ppt. (low yield) removed, pulverized in a mortar, washed successively with water, EtOH, CS_2, EtOH, and Et_2O, and dried *in vacuo*, yields *phenylbiguanide hexasulfide*, $(C_8H_{11}N_5)_2.H_2S_6$ (VIII), orange-yellow, m. 130–5°, stable when dry (did not lose H_2S when kept all summer at 26–30°), decomps. very slowly in cold water and rapidly in hot water (liberation of S), and decomps. slowly in EtOH (liberation of H_2S). Under no conditions was the disulfide of Romani isolated. Thus with $(NH_4)_2S_x$ contg. less S (prepd. as above but with 30 instead of 70 g. of S per 200 cc. of NH_4OH) only I was obtained. On increasing the quantity of S to 45 g., a mixt. of I and VII was obtained. To obtain VIII, it is necessary to adhere strictly to the proportions noted above; otherwise mixts. are obtained. These mixts. with HCl evolve H_2S and H persulfide seps., whereas pure VIII and HCl give only H persulfide. This difference is strictly analogous to the behavior of strychnine hexasulfide (IX) with acids. Besides the orange-red IX obtained by Hofmann (cf. *Ber.* 1, 1868; 10, 1087) from cold satd. alc. strychnine (X) and alc. $(NH_4)_2S_x$, the IX prepd. by Schmidt (cf. *Ann.* 180, 287) from alc. X and H_2S was also obtained, and in this latter case the compn. of the IX is, contrary to Schmidt, identical with that obtained by the method of Hofmann. Cold satd. (8%) alc. $(PhHN)_2C{:}NH$ (4 g.) and S (3 g.) in suspension treated with H_2S, let stand in a sealed vessel, filtered, the residue washed successively with EtOH, CS_2, EtOH and Et_2O, and dried *in vacuo*, yields *diphenylguanidine hexasulfide* $(C_{13}H_{13}N_3)_2.H_2S.S_5$ (XI), m. 100–10° (to a red liquid), stable when kept dry, decomps. slightly in cold water and more so in EtOH. When the S in the prepn. is diminished even as low as 0.5 g. of S (*loc. cit.*), XI is still obtained but the yields are smaller. XI is also obtained from aq. $(PhHN)_2C{:}NH.H_2SO_4$ or other salts and aq. $(NH_4)_2S_{2.5}$ (from NH_4OH of d. 0.92). Unlike VIII, XI liberates H_2S and S when treated with acids. Therefore either it first forms a persulfide, and this is unstable, or its structure is like that of strychnine polyiodide (the more probable hypothesis). Prepd. like XI, though the passage of H_2S must be much longer, *di-o-tolylguanidine heptasulfide* $(C_{15}H_{17}N_3)_2H_2S.S_6$ (XII), is stable when kept dry, decomps.

slowly in cold org. solvents, and with acids liberates H_2S and S. Since di-*o*-tolylguanidine (XIII) is only slightly sol. in cold EtOH (3% at 25°), it may be preferable to pass H_2S into boiling satd. alc. XII. XII is also formed when XIII·HCl or other XIII salt soln. is poured into excess of aq. $(NH_4)_2S_{2.5}$. XII is the 1st heptasulfide of an org. base described in the literature. Di-*p*-tolylguanidine and di-*m*-tolylguanidine give with H_2S and S sed solns., which probably contain the corresponding polysulfides, but in neither case could the polysulfide be isolated by evapn. *in vacuo* with a current of H_2S. Prepd. in the same way as XI and XII, *asym. triphenylguanidine hexasulfide* $(C_{19}H_{17}N_3)_2.H_2S_6$ is canary-yellow, decomps. in org. solvents (with evolution of more H_2S than from XI and XII); with acids it liberates H_2S and H persulfide. *Sym. triphenylguanidine polysulfide* is readily formed in the same way, but the orange-yellow product which seps. is unstable, and liberates large quantities of H_2S when it is being washed with CS_2. It also loses H_2S *in vacuo* and could not, therefore, be analyzed. Brucine polysulfide, $(C_{20}H_{22}N_2O_3)_3.2H_2S_6$, prepd. by Schmidt (*loc. cit.*) from 1% alc. brucine and H_2S, was formed whether or not air was excluded, but its formation was more rapid in air. Contrary to Schmidt, the product is stable. The yellow hydrated polysulfide, $(C_{20}H_{22}N_2O_3)_3.H_2S_6.6H_2O$, was also obtained by the method of Schmidt, and his data were confirmed. All attempts to isolate polysulfides of other alkaloids in a pure state were without success. From alc. quinine, quinidine, cinchonine and codeine, passage of H_2S in the presence of S for several days pptd. the corresponding polysulfides, but in no case could the product be purified sufficiently for analysis. The *detn. of H_2S in sulfides and hyposulfites* can be made conveniently by the ordinary volumetric method by means of standard I solns. but in sealed tubes, *i. e.*, putting the sample in a tube into another tube contg. excess I and HCl, and sealing this latter tube. When the reaction is completed, the tube is let stand 12 hrs. before opening and titrating back with $Na_2S_2O_3$ (which is carried out with addn. of CS_2 to dissolve the I mixed with the sepd. S). C. C. DAVIS

Oxidation of sulfides with benzoyl hydrogen peroxide. IV. L. N. LEVIN AND I. CHULKOV. *J. prakt. Chem.* **128**, 171–9(1930).—Correction. Benzoyl peroxide in (*A* **25**, 911 should read benzoyl hydrogen peroxide. L. T. C.

Isonitriles. XVII. Reactions with nitroso derivatives. MARIO PASSERINI WITH NICOLETTA ZITA. *Gazz. chim. ital.* **61**, 26–33(1931); cf. *C. A.* **21**, 3197.—The present paper begins a study of the behavior of isonitriles with aromatic nitroso and isonitroso derivs., and deals with nitrosonaphthols. In hot C_6H_6, PhNC (I) reacts easily with α,β-$C_{10}H_6(NO)OH$ (II), but the product is a black pitchy mass from which no definite compd. could be isolated. On the other hand, *p*-$CNC_6H_4N_2Ph$ (III) (cf. P., *C. A.* 15, 2279) is particularly well adapted for a study of the reaction. Concd. III (20.7 g.) in anhyd. C_6H_6, II (17.3 g.) and $CaCl_2$ (5 g.) refluxed 6 hrs. (CO, CO_2 and H_2O are evolved), concd., let stand several hrs., the ppt. filtered, washed with C_6H_6 and then with water (16.5 g. of crude product), and recrystd. from C_6H_6, yields *p-benzeneazoanilcarbonyl-α-amino-β-naphthol* (IV), $O.C_{10}H_6.NH.C\,NC_6H_4N{:}NPh$, yellow, m. 241–3° (decompn.), has a tendency to entrain C_6H_6 in the crystn. Omission of the $CaCl_2$ gives lower yields, and the product is contaminated with secondary products which give it a black color with violet reflection. IV in a great excess of concd. HCl and excess of Sn heated 40–50 min. on a water bath until the mixt. (at first intensely red) becomes colorless, a great excess of KOH added, cooled, the ppt. filtered, washed with water (the white color tends to become violet, and the wash waters contain $PhNH_2$), dried *in vacuo* over H_2SO_4, extd. with boiling C_6H_6, the ext. decolorized with charcoal, filtered, concd. to a small vol., cooled, and the ppt. recrystd. from C_6H_6, yields *p-aminoanilcarbonyl α-amino-β-naphthol* (V), m. 220–1° (decompn.) (yield, 6 g. from 10 g. of III), sol. in aq. acids (repptd. by alkalies); treated in EtOH with alkalies, it gives a violet-blue color, and with $FeCl_3$ an intense blue, holds C_6H_6 tenaciously when crystd. (must be dried at 120° *in vacuo*). The C_6H_6 mother liquors from the prepn. of V contain a small quantity of an unidentified compd., m. approx. 165°. V moistened with a little MeOH, a slight excess of BzH added, heated until homogeneous, cooled, filtered, the residue washed with MeOH, then with water contg. a little Na_2CO_3, and recrystd. from C_6H_6, yields *p-benzalaminoanilcarbonyl-α-amino-β-naphthol* (VI), yellow, m. 205–8°. Following the same reduction of IV with Sn and HCl but prolonging the heating for 2 hrs., decanted hot, the soln. evapd. to a small vol., the residue boiled in excess 20% aq. NaOH, the ppt. dissolved in C_6H_6, and fractionally crystd. yields V and an identified *basic compd.*, turns brown at 77°, m. 92–5°, could not be purified sufficiently for analysis. The NaOH mother liquor acidified with HCl, the ppt. dried, dissolved in hot C_6H_6, decolorized with charcoal, filtered, and recrystd. yields carbonyl-α-amino-β-naphthol

(VII) (cf. Meyer, *C. A.* 10, 594). An intimate mixt. of V and excess solid KOH heated over a flame, the vapors collected as an oil, allowed to solidify, and recrystd. from C_6H_6, yields *p*-$C_6H_6(NH_2)_2$. By the same procedure as with I, β,α-$C_{10}H_6(NO)OH$ (VIII) and III yield 4,4'-formamidineazobenzene (cf. P., *C. A.* 17, 1632), m. 196–7°. When evapd., the C_6H_6 mother liquor yields formyl-*p*-aminoazobenzene. In dissolving the solid product from the reaction of VIII and III, a small quantity of an unidentified brown-black *compd.*, insol. in all solvents, remained undissolved. Further expts. have been started on the reaction of isonitriles with true NO derivs., *e. g.*, PhNO. I and PhNO boiled in C_6H_6 form, besides resinous products, $(PhNH)_2CO$ and a red *compd.*, m. 212–3°, which analysis indicated as an integral condensation product of 3 mols. of I, with no PhNO in combination. It is therefore not a trimer, but a true condensation compd. With PhNO, III reacts like I. This investigation is to be published in more detail in a forthcoming paper. C. C. Davis

Derivatives of *m*-xylenols. II. Intermediate products from *m*-2-xylenol (2-hydroxy-1,3-dimethylbenzene). F. M. Rowe, S. H. Bannister and R. C. Storey *J. Soc. Chem. Ind.* 50, 79–80T(1931); cf. *C. A.* 25, 930.—2,6,4-$Me_2(NH_2)C_6H_2OH$ (I) was prepd. in 92% yield from 2,6-$Me_2C_6H_3OH$ (II) by coupling with PhN_2Cl and reducing with $Na_2S_2O_4$, and in 79% yield by reducing the corresponding NO compd. with $Na_2S_2O_4$. I, leaflets from H_2O or C_6H_6, m. 137–8° (decompn.), gives a di-Ac deriv., m. 160°. With 2,4-$(NO_2)_2C_6H_3Cl$ in the presence of Cu, I gave 2,4-dinitro-4'-hydroxy-3',5'-dimethyldiphenylamine, m. 193°. 2,6-$Me_2C_6H_3OMe$ (III), b. 182–3°, was prepd. from II and Me_2SO_4. III was best nitrated by gradually adding 103 cc. of 70% HNO_3 to 50 g. III in 75 cc. of AcOH and warming at 60–70°. This gave 2,6,4-$Me_2(NO_2)C_6H_2OMe$ (IV) in 50% yield, m. 92°, which was hydrolyzed with 60% H_2SO_4 to give 2,6,4-$Me_2(NO_2)C_6H_2OH$, m. 169–70°. Reduction of IV to 2,6,4-$Me_2(NH_2)C_6H_2OMe$ (V), m. 66°, was best done with Fe; $SnCl_2$ gave hydrolysis. V gave an Ac deriv. (VI) m. 136–7°. IV and $Na_2S_2O_4$ gave 89% of 2,6,4-$Me_2(NH_2)C_6H(OMe)SO_2Na$(3), from which the SO_2H group can be easily hydrolyzed to give V. V reacts with β-hydroxynaphthoic acid in the presence of PCl_3 to give 99% of the 3,5-dimethyl-4-methoxyanilide needles from EtOH. This gives red colors on coupling with diazo compds. VI is easily nitrated in AcOH, giving 96.5% of 2 nitro-3,5-dimethyl-4-methoxyacetanilide, pale yellow, m. 128°. The Ac group can be hydrolyzed off with NaOH or HCl, producing 1-methoxy-2,6-dimethyl-3-nitro-4-aminobenzene, m. 47°, which is converted to the corresponding 3,4-isoxadiazole oxide, m. 96°, by boiling with NaOCl. G. R. Yohe

Preparation of salicylyl chloride. A. Kirpal. *Ber.* **63B**, 3190(1930).—By adding a little $AlCl_3$ *o*-$HOC_6H_4CO_2H$ can be made to react with $SOCl_2$ at a temp at which secondary reactions do not occur; when 10 g. of the acid, 7 cc. $SOCl_2$ and 0.02 g. $AlCl_3$ are kept at 45–50° the reaction is complete in 1.5 hrs. if the acid was sufficiently finely divided. Removal of the excess of $SOCl_2$ *in vacuo* leaves a mobile liquid solidifying in ice and showing, without further purification, the m. p. 18° given by Kopetschni and Karczag for *o*-HOC_6H_4COCl. C. A. R.

Constituents of the volatile oil from the leaf of Chamaecyparis obtusa, Sieb. et Zucc., **F. Formosana, Hayata or Arisan-Hinoki. I.** Kinzo Kafuku, Tetsuo Nozoe and Chuta Hata. *Bull. Chem. Soc. Japan* **6**, 40–53(1931).—Steam distn. of leaves of *Chamaecyparis obtusa* gave 0.3% of oil, slightly yellow changing to red on standing, d_{28} 0.8988, n_D^{25} 1.4878, $[\alpha]_D^{25}$ —5.83°, acid value 0.96, ester value 12.63, ester value after acetylation 54.81. From 5 kg. of oil, 12 g. of acids and 1.5 g. of phenols were obtained by extn. with 5% KOH and subsequent regeneration of the ext. in the usual manner with CO_2 and H_2SO_4. On vacuum fractionation of the acids the main portion was an unsatd. acid apparently of the aliphatic terpene group, $C_{10}H_{16}O_2$, b_8 133–5°, d_4^{20} 0.9544, n_D^{20} 1.4732, $[\alpha]_D$ 0°, mol. refraction 49.40. The remainder of the acid fraction consisted apparently of *hinokic acid*, m. 165–6°, lower fatty acids and traces of phenols. The oil remaining after extn. of the acids on vacuum fractionation yielded 34.1% of terpenes and 11.4% of terpene alcs. Of the terpenes 50% was *d-sabinene*, $[\alpha]_D^{17.5}$ 86.4°, and 20–30% *chamene* (I), a new terpene, b_{10} 86–8°, b_{760} 168 70°, d_{45}^{2} 0.8228, n_D^{25} 1.4686, $[\alpha]_D$ 35°, mol. refraction 46.00. Satn. of the cold ether soln. of I with dry HCl gas gave the hydrochloride, b_{11} 80–90°, d_{25} 1.0196, n_D^{25} 1.4783, mol. refraction 58.09. Shaking 20 g. of I with 20 cc. H_2SO_4 (1:3) at room temp. gave *isochamene* (II), b_{10} 88–90°, d_4^{25} 0.8222, n_D^{25} 1.4726, $[\alpha]_D^{25}$ —0.27°, mol. refraction 46.42, and, contrary to chamene, fairly stable to atm. oxidation. II with alc. H_2SO_4 (1:1) polymerized to *diisochamene*, b_4 155–6°, d_4^{20} 0.9150, n_D^{20} 1.5134, $[\alpha]_D^{20}$ —0.7°, mol. re-

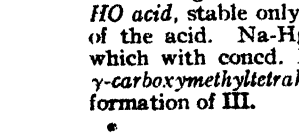
fraction 89.40. II with HNO_2 in benzene gave *α-terpinene nitrosite*, apparently by rearrangement of isochamene nitrosite. I gave a deep red color in Ac_2O on addn. of 1 drop of H_2SO_4. Other terpenes found were *α-pinene*, *α-thujene*, *p-cymene*, *α-terpinene*, *γ-terpinene* and dipentene. The terpene alcs. consisted of *d-Δ-terpineol-4*, *borneol*, *l-linaloöl*, and its esters, and an octenol, $C_8H_{16}O$, d_4^{30} 0.8454, n_D^{30} 1.4441, $[\alpha]_D^{30}$ —10.62°, and its esters.

R. C. ELDERFIELD

Bitolyl series. I. A. ANGELETTI WITH A. BRAMBILLA. *Gazz. chim. ital.* **60**, 967–74(1930).—The growing interest and importance of the Ph_2 group induced A. to start a systematic series of expts. on bitolyl compds. Of these, the 2,2'- and 6,6'-dimethylbiphenyl derivs. are of special importance because of the cases of optical stereoisomerism without asym. atoms (cf. Mascarelli, *C. A.* **22**, 68; **23**, 2962, 3694; *Atti III congresso naz. chim. pura applicata* Firenze 249–62(1930); Meisenheimer and Höring, *C. A.* **21**, 2892). 4,5-Cl(O_2N)C_6H_2Me was converted to *o,o'*-dinitrobitolyl by the reaction of Ullmann and Bielecki (cf. Mascarelli and Pirani, *Gazz. chim. ital.* **41**, i, 70(1911)) and this was partially reduced with alc. $(NH_4)_2S$ by the method of Mascarelli and Gatti (*C. A.* **24**, 2121) to 2-amino-2'-nitro-4,4'-dimethylbiphenyl (I). I (5 g.) in 7% H_2SO_4 (200 cc.) diazotized at 4° with aq. $NaNO_2$ (1.6 g. in 25 cc.), poured slowly into a large excess of KI in 10% H_2SO_4 at 100° (cf. Gelmo, *Ber.* **39**, 4175(1906)), decolorized with SO_2, the semi-oily product dried *in vacuo*, extd. with Et_2O (a small quantity of insol. black residue is probably bitolyleneiodonium iodide (II), for treated with moist Ag_2O at 60°, filtered, KI added to the filtrate, and the yellow powder recrystd. from boiling water, it yields a yellowish compd. which turns brown at 198° and m. 204–5° (decompn.), while Mascarelli and Pirani (*loc. cit.*) give a m. p. of 206° for II), the ext. extd. with aq. NaOH, the residue evapd., steam-distd., the 1st portion of the distillate (a small yield of 4,4'-dimethylbiphenylene oxide (III) (cf. *Ber.* **34**, 3336(1901)) the later portion (oil which solidifies to a yellow mass) dissolved in petr. ether (b. p. 70–80°), concd., and the cryst. ppt. recrystd. from 80% EtOH yields 0.70 g. of *2-iodo-2'-nitro-4,4'-dimethylbiphenyl* (*o*-iodo-*o'*-nitrobitolyl), pale yellow, m. 83–4°. The same procedure was used in an attempt to prep. the corresponding Br deriv., but only resinous products which could not be purified were formed. A very small yield was obtained by diazotizing I-HBr in presence of CuBr, following, in general, the method of Dobbie, Fox and Hoffmeister (cf. *C. A.* **5**, 3048; **6**, 593) for the prepn. of 2,2'-dibromobiphenyl. I (12 g.) and hot water (100 cc.) added to aq. HBr (45 cc. of d. 1.49) and freshly prepd. CuBr (16 g.), all air removed from the flask by CO_2, heated on a water bath, diazotized with aq. $NaNO_2$ (4 g. in 50 cc.), (maintained at approx. 100°), heated 1 more hr. at 100°, cooled, dild. with water, the product (a black pitch contg. a yellow solid), washed with water, dried *in vacuo*, extd. with Et_2O (the black residue contg. Cu will be studied later), the ext. washed with aq. NaOH, dried, evapd., the semi-oily residue (5 g.) steam-distd., yields 2 portions: (1) a white substance (2 g.) of agreeable odor and (2) brown pitch. Portion (1) recrystd. from 95% EtOH (very sol.) and then from 80% EtOH, yields 0.40 g. of III, which in this case is difficult to purify because of contamination with the chief product. The 95% alc. mother liquor from the 1st crystn. of III contains a trace of 4,4'-dimethylcarbazole. Portion (2) steam-distd. again yields an oil which partially solidifies, and which crystd. from 70% EtOH yields after long standing 0.25 g. of *2-bromo-2'-nitro-4,4'-dimethylbiphenyl* (*o*-bromo-*o'*-nitrobitolyl) (IV), pale yellow, m. 73–4°. The most convenient method for prepg. the Cl deriv., though the yield is very low, is the following. I (12 g.) in a mixt. of concd. HCl (50 cc.) and water (200 cc.), diazotized hot with aq. $NaNO_2$ (4 g. in 50 cc.) and fresh CuCl (16 g.), the black resin extd. with Et_2O, the ext. washed with aq. NaOH, dried, evapd., the oily residue (approx. 4 g.) steam-distd. (III first distils in small quantity as before), and the later oily distillate crystd. repeatedly from 70% EtOH, yields 0.22 g. of *2-chloro-2'-nitro-4,4'-dimethylbiphenyl* (*o*-chloro-*o'*-nitrobitolyl), light yellowish, m. 85–6°. Attempts were made to prep. 2-hydroxy-2'-nitro-4,4'-dimethylbiphenyl (V), but the product could not be purified. In one case the soln. of diazonitro deriv., decompd. by bubbling in steam in the presence of urea, yielded a small quantity of III, while the chief product (also a very small yield of acidic nature) repeatedly dissolved in aq. NaOH and repptd. with HCl, yielded a brown-red, amorphous product which could not be steam-distd., sublimed or otherwise purified. Likewise no success was had in decompg. the diazo deriv. by pouring the soln. in hot dil. H_2SO_4. Finally attempts were made to acetylate the reaction product, but starting from 3 g. of product (from 20 g. of I) there was obtained, after acetylation, by crystn. from 80% EtOH, a red-yellow cryst. *compd.*, m. 99–100°, mixed with a yellowish powder. The yield was so low that it could not be identified. If II is formed from small quantities of diamino deriv. as an impurity, the same explanation does not apply to the formation of

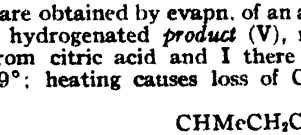
III, for the yield of III in the prepn. of IV is too great to be accounted for thus. In the decompn. of the diazonitro deriv., the hydroxynitro deriv. 4,6-Me(HO)C_6H_3-$C_6H_3(NO_2)$Me-2,4 (VI) is formed initially, and this by elimination of 1 mol. of HNO_2 passes to III. This hypothesis is supported by the fact that it was impossible to obtain V in the attempts in which III was formed. Furthermore it is possible that, by the action of water, the NO_2 group in VI is replaced by OH, a reaction which occurs in polynitro derivs. (cf. Claessen, *Ger. pat.* 289,446). The di-HO deriv. thus formed passes readily by elimination of water, to III (cf. *Ber.* **25**, 2745(1892)). The tendency of the Ph_2 derivs. to form heterocyclic, pentatomic nuclei is observed in numerous other cases (cf. Mascarelli, *C. A.* **3**, 781; **23**, 3694; Treche, *Thesis Bologna* **1911**; Dobbie, Fox and Hoffmeister, *loc. cit.*, Mascarelli and Gatti, *loc. cit.*). C. C. DAVIS

Remark on the work on "aromatic thio ketones." E. BERGMANN. *Ber.* **63B**, 3225(1930).—In connection with the statement in the paper abstracted in *C. A.* **25**, 1239, that aromatic thio ketones react with Na apparently differently from the O analogs, Schönberg has drawn B.'s attention to the fact that he (S.) first observed the reactivity of thio ketones toward Na (*C. A.* **20**, 364). C. A. R.



Stereochemical structure. II. Optically active α- and β-methylhydrobenzoin. ROBERT ROGER. *Biochem. Z.* **230**, 320-9(1931); cf. *C. A.* **24**, 3000.—*d*(+)-PhAcCHOH (I) was prepd. by Neuberg's carboligase method (*C. A.* **17**, 1484) and also from *d*(−)-mandelamide and MeMgI. I and PhMgBr give *d*(+)-*methylhydrobenzoin* (*α-form*) (II), m. 92–3°, $[\alpha]_{5893}$ 31° in acetone, 40° in EtOH. *d*(+)-Methylhydrobenzoin(*β*-form) (III), m. 80–1°, $[\alpha]_{5893}$ 31° in acetone, 21° in EtOH, prepd. from *d*(−) benzoin and MeMgI, is not identical with II as shown by mixed m. ps. The compd. Neuberg prepd. from I and PhMgBr, which he called III is not identical with II or III, but may be a phys. modification of II. *d*(+)-*2-Methyl-2-hydroxy-1,1-diphenyl ethanol* (IV), m. 92–3°, $[\alpha]_{5893}$ 133° in acetone, was prepd. from PhMgBr and Et *d*(+)-lactate. IV is not identical with II or III as shown by the color with concd. H_2SO_4, and mixed m. ps. Hence I reacts as such and does not rearrange to BzMeCHOH

D. S. SEARLE



Synthesis of munjisthin. P. C. MITTER AND HAROGOPAL BISWAS. *Nature* **126**, 761(1930).—Munjisthin is a dihydroxyanthraquinonecarboxylic acid occurring in *Rubia munjistha*. It has been synthesized from 2,6-Cl(MeO)C_6H_3Me and $C_6H_4(CO)_2O$.

A. L. HENNE

Partially hydrogenated lactones of naphthalenes. GEORG HUPPMANN. *Süddeut Apoth.-Ztg.* **71**, 137-9(1931).—In the present study it is shown that relatively good yields of partially hydrogenated lactones are obtained by condensation of *ar-β*-tetralol (I) with HO acids or *β*-ketone acid esters in the presence of concd. H_2SO_4. Thus, malic acid and I give CO + 3 H_2O + *tetrahydronaphtho-α-pyrone* (II), m. 131°. Similarly, $AcCH_2CO_2Et$ and I give *γ-methyltetrahydronaphtho-α-pyrone* (III), m. 154°. On heating with alkalies the lactone ring is opened with formation of the corresponding *HO acid*, stable only in the form of its salts which are obtained by evapn. of an alk. soln. of the acid. Na-Hg converts the acid into the hydrogenated *product* (V), m. 107°, which with concd. H_2SO_4 gives the lactone. From citric acid and I there resulted *γ-carboxymethyltetrahydronaphtho-α-pyrone* m. 189°; heating causes loss of CO_2 with formation of III.

W. O. EMERY

Conjugated double bonds. XV. Constitution of indolenine yellow. RICHARD KUHN, ALFRED WINTERSTEIN AND GEORG BALSER. *Ber.* **63B**, 3176-84(1931); cf. *C. A.* **25**, 1513.—As a rule, replacement of methine groups, =CH—, in a polyene chain by =N— has practically no influence on the color. Deviations from this rule occur in the initial members of homologous series and seem always to lie in the direction of stronger absorption by the N-contg. compds. An apparent exception was afforded by the violet indolenine red (I) (pure red in soln.), obtained from the methylene base (II) and salts or esters of HCO_2H, and the greenish yellow compd. (III) (called *indolenine yellow* in the present paper), obtained according to Ger. pat. 459,616 from II and HNO_2 and which, by analogy, was assigned the structure IV. It has been found, however, that in the condensation of bases of type II with HNO_2 in the presence of Ac_2O not only H_2O but also 1 mol. HCN is split off. The yellow dye is therefore given

the structure III, which makes it a lower vinylene homolog of I and most satisfactorily explains its color. Attempts to obtain III by condensing 1,2,3,3-tetramethylindolenium salts with 1,2,3-trimethylindolinone (V) were unsuccessful. If, however, II in cold AcOH is slowly treated with 1 mol. $NaNO_2$ in a little water and then pptd. with $HClO_4$, there seps. an *oxime perchlorate* (VI) which with II in Ac_2O yields III but also decomps., when heated in Ac_2O, into V, $HClO_4$ and HCN; in the absence of II this decompn. is very smooth and affords a better method of prepg. V than does oxidation of II with $KMnO_4$. If the formula III is correct, the condensation of II with the *1,3,3;5,7-penta-Me homolog* (VII) of VI on the one hand, and of the 1,3,3,5,7-penta-Me homolog of II with VI on the other hand, should give 2 different di-Me derivs., but as a matter of fact the same dye (VIII) was obtained in both cases. This can be explained on the basis of König's theory that in dyes of this type the anion is not arrayed with the one or the other N atom but with both simultaneously, giving rise to a system of "fluid heteropolar unions," as represented by formula IX. The derivation of an electronic formula, in which this equivalence of the two N atoms is brought out, is briefly discussed. *1,3,3-Trimethyl-2-formoxime-indolinium 1-perchlorate* (VI) (96% yield), m. 215° (Berl block, cor.) with decompn. *Perchlorate* of III, m. 267° (Berl block, cor.) with decompn. Free III, m. 147°. VII, m. 210° (decompn.). *5,7-Di-Me deriv.* (VIII) of III, isolated as the *perchlorate*, yellow, m. 250.5° (decompn.).

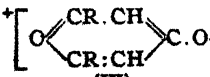
C. A. R.

Relationships between dipyrylenes and *meri*- as well as *holo*-dipyrylium salts. Action of halogens on fulvenes. F. Arndt and L. Lorenz. *Ber.* **63B**, 3121–32(1930).—The results of these expts., which were completed 4 yr. ago (L., *Diss. Breslau* **1927**) were to be published later in connection with others and are now given separately only on account of the appearance of the paper by Bergmann and v. Christiani (*C. A.* **25**, 1236–7). They assign to the hexabromide of dixanthylene (I), which A., Scholz and Nachtwey had represented as a dixanthonium or dixanthylium perbromide (II), the structure $O(C_6H_4)_2C(Br.Br_2)C(Br.Br_2)C(C_6H_4)_2O$ (III), but A. and L. believe that II is in better agreement with the known facts, such as the existence of those other dixanthylium salts with the same cation but different anions described by Werner, the formation of an analogous hexabromide by dithioxanthylene (IV) but not by the *disulfone*, the behavior toward Br of tetraphenyldipyrylene (V) and dipyrylenetetracarboxylic ester (VI). From all these it follows that the behavior of the xanthenes and dipyrylenes toward halogens is not comparable with that of open and carbocyclic fulvenes; the Br addn. product (II) of I contains all its Br in the form of 2 anions, $BrBr_2$, and the manner and ease of such Br addn. depends materially on the possibility of a change from a quinoid pyrone to a benzenoid pyrylium form. This does not mean that formula II completely represents the actual state of the compd. If it be assumed that the Bergmann formula III is changed only in that the $BrBr_2$ groups are represented as anions, there results a dicarbenium salt in the cation of which all the at. nuclei occupy the same relative positions as in the dioxonium cation of II, the 2 salts differing from each other only in the distribution of the "bonds" and "charges." Between these 2 extreme forms there conceivably exists that "intermediate stage" recently discussed (*C. A.* **25**, 2145), and it may be assumed that in the hexabromide of I the "intermediate stage" lies far on the side of the pyrylium or oxonium form (II) but that there is still present a residue of carbenium unsaturatedness which plays a role in the color of the hexabromide. The expts. described in this paper were based on the following line of reasoning. γ-Pyrones $O(CR:CH)_2O$ (VII), like ordinary ketones, add the H nucleus of an acid at the C:O group but instead of an unsatd., positively charged



carbenium group they form a satd. positive oxonium group and an aromatic ring, the resulting salts (VIII) therefore being colorless and much more stable than ordinary ketone salts. A. and L. assume that such inner satn. in the direction of the betaine form (IX) has already begun in the free γ-pyrones which therefore do not behave like unsatd. ketones; in VIII and IX the electron-seeking γ-O atom has attracted an electron from the C, as manifested by the replacement of the "double bond" in VII by the "single bond" in VIII and IX. The excess negative charge which the O atom thereby acquires is compensated for in VIII by the newly introduced H nucleus but is still present in IX. A diperylene system $O(CR:CH)_2C:C(CH:CR)_2O$ (X), however, can of itself not undergo such an inner satn. since there is no electron-seeking atom on the central or γ-O atoms, and such a system (insofar as it is not condensed with C_6H_6 rings as in I) is a true fulvene system and intensely colored. Its latent tendency to pyrylium formation can be brought out only by (1) introduction of an electron-seeking atom or group on the one γ-C atom or (2) complete removal of 1 of the 2 pairs of electrons (*i. e.*, of 2 electrons) of the double bond. The simplest example of (1) is where the newly introduced atom is the H nucleus of a strong acid, with formation of the *meri*-dipyrylium salt (XI). (2), on the other hand, is equiv. to an oxidation and from X or from XI, in the absence of the necessary anions, there results the *holo*-dipyrylium salt (XII). The XI are more deeply colored than the X themselves and the XII are in general considerably less deeply colored. The XII are most simply prepd. from the X with Cl or Br, the halogen acting as an oxidizing agent and also furnishing the anion (the Br anion adds another mol. of Br_2 to give II). The resulting dichlorides exist in 2 forms (red and black) which rearrange into each other with extreme ease in a non-controllable manner. It is assumed that the red forms are the *holo*-salts while the black forms have the structure XIII, the Cl_2 splitting into Cl^- and Cl^+ and the latter adding at 1 of the central C atoms. I, faintly greenish yellow, m. 325°, dissolves in hot *o*-$C_6H_4Cl_2$ with blue-green color (light yellow in the cold), forms a blue-green melt, shows intense light-blue fluorescence under the quartz lamp. Thioxanthone, very faintly yellow, m. 213°, shows yellow fluorescence in ultra-violet light. Thioxanthione, dark needles with green surface luster, m. 176°, sol. in C_6H_6 with red color (by transmitted light, green by incident light or in thin layers), in $CHCl_3$ with pure green, in concd. H_2SO_4 with dark orange color. IV, m. 365°, shows blue fluorescence in ultra-violet light. Thioxanthone gives on reduction according to F. Mayer a compd. m. 346° but behaving toward Br like IV. *Dithioxanthylene disulfone*, from IV and H_2O_2 in AcOH, gradually darkens between 380° and 500°, melts at red heat on Pt, does not react with Br soln. or vapor even on heating. *Dixanthionium perbromide*, crimson, darkens 220°, decomps. 245°, regenerates IV with Zn dust and AcOH. *meri-Perchlorate* from V, obtained by boiling finely divided V (pptd. from C_5H_5N with water) in AcOH under CO_2, filtering and adding 70% $HClO_4$, brown-black, decomps. 287–8° with considerable violence. *holo-Perchlorate*, from V and $HClO_4$ at about 200°, red, deflagrates vigorously when heated. *meri-Perchlorate* from VI, red needles, changes in hot concd. H_2SO_4 or 70% $HClO_4$ or on treatment in cold AcOH with $HClO_4$ and Br from deep red to green. Tetraphenyldithiopyrylene (XIV) in $CHCl_3$ adds only 2 atoms Cl in CCl_4, forming 2 mutually interconvertible *dichlorides* (red and black); the red form darkens around 80°, both sinter 100° and decomp. 300–10°. *Dichlorides* of V; the red rapidly changes into the black form which sinters around 100°, m. 305°. With Br in $CHCl_3$ XIV gives a *hexabromide*, golden yellow, loses Br at 80–100° on slow heating, becomes smeary at 120°.

C. A. R.

Some 2,4-substituted derivatives of pyridine. RODERICH GRAF (WITH ERNST

LEDERER-PONZER AND LEOPOLD FREIBERG). *Ber.* **64B**, 21–6(1931); cf. *C. A.* **23**, 837.—**4-Chloro-** (I) and **4-iodopicolinic acid** (II) were degraded by the Curtius method through the hydrazide and azide to *4-chloro-* (III) and *4-iodo-2-aminopyridine* (IV). Attempts to convert the I by the Naegeli method through the chloride directly into III failed because of the slight reactivity of the chloride with NaN_3. In C_6H_6 the chloride with $N_2H_4.H_2O$ gave *di-4-chloropicolinic hydrazide* (V). The simple *hydrazide* (VI) was best prepd. by converting the I with $SOCl_2$ into the chloride, then with excess of MeOH into the Me ester which gave the VI almost quant. Attempts to degrade the VI directly to the urethan, without isolating the azide, by boiling in abs. alc. with AmONO gave a difficultly sol., unreactive *substance* which carbonized at 272° without melting. On the other hand, the azide boiled with dil. AcOH gave III directly. By the Schotten-Baumann method, III gives the di-Bz deriv., converted by long boiling with alc. into the mono-Bz deriv. I, faintly yellowish, m. 180–1°, was obtained in 50–5% yield by refluxing anhyd. picolinic acid-HCl in $SOCl_2$ for 10 days and decompg. the resulting chloropicolinyl chloride-HCl with H_2O. V, faintly yellowish, m. 269–71° (decompn.). VI, from the *chloride* (m. 46°), m. 167–8° (18 g. from 18.5 g. of I); *benzal deriv.*, m. 178°. *Azide*, from VI in cold *N* HCl with aq. KNO_2, m. 92°, deflagrates on rapid heating, gives with 1:1 AcOH on the water bath N, CO_2 and III (3.2 g. from 7.4 g. VI), m. 130–1°, easily volatile with steam; *picrate*, yellow, m. 243–4°. *N-Carbethoxy deriv.* of III, from the azide and boiling abs. alc., m. 161°, best hydrolyzed by const.-boiling HI, which gives III. *HI*, m. 206–7°, soon turns yellow in the air. *N,N-Di-Bz deriv.* m. 165–6° *N-Bz deriv.*, m. 120–1°. *N-Ac deriv.*, from III and boiling Ac_2O, m. 115–6°. *2-HO compd.*, from III in dil. H_2SO_4 with the calcd. amount of KNO_2, m. 184°, only slightly sol. in dil. acids. *2,4-Dichloropyridine*, from III by the Sandmeyer method (about 1 g. from 5 g. III), b. about 184°, m. 0°, almost insol. in dil. acids, exceedingly volatile with steam, forms a cryst. double salt with $HgCl_2$ but no picrate. II from I refluxed in HI (d. 1.7) with some red P, m. 169° (decompn.), cannot be converted into the chloride with $SOCl_2$ because of exchange of the I for Cl. The Me ester, from II and MeOH-H_2SO_4, yielded with concd. alc. NH_3 the *amide*, m. 158°, and with alc. $N_2H_4.H_2O$ the *hydrazide*, m. 160–1° (*benzal deriv.*, m. 207–8°). IV (through the *azide*, m. 89° (foaming)), m. 163–4°; *picrate*, yellow, m. 253–4°; *N-carbethoxy deriv.*, m. 167°; *N,N-di-Bz deriv.*, m. 176–7°; *N-Bz deriv.*, m. 167–8°; *N-Ac deriv.*, m. 150°; *2-HO compd.*, m. 195°. C. A. R.

Imide and amide chlorides of non-aromatic acids. VI. A new way in the quinoline series. JULIUS V. BRAUN AND ALBRECHT HEYMONS (WITH L. SCHNITZSPAHN). *Ber.* **63B**, 3191–203(1930); cf. *C. A.* **24**, 2999.—Wallach assigned the structure $MeC(:NR)CH_2CCl:NR$ to the compds. obtained by condensation, with loss of 1 HCl, of 2 mols. of the imide chlorides, $MeCCl:NR$, derived from AcOH, but it was later shown that they are amidines, $MeC(:NR)NRCCl:CH_2$, *i. e.*, that the condensation takes place between a C and N atom. It was thought that imide chlorides of the type $R'CH_2CCl:NR$ undergo a similar condensation, since Wallach, and later Bischoff and Walden, had found that $ClCH_2CONHPh$ gives a compd. $C_{16}H_{12}N_2Cl_2$ (I), whose formation through an intermediate imide choride, $ClCH_2CCl:NPh$, could readily be explained by the equation $2\ C_8H_7NCl_2 = I + HCl$. I, however, is characterized by an unexpectedly strong, bright yellow color and by the surprising ease (treatment with cold Na_2CO_3) with which it loses another mol. of HCl, and in addn. to the Wallach formula, $ClCH_2C(:NPh)CHClCCl:NPh$, Bischoff and Walden suggested the structure of a HCl salt $ClCH.C(:NPh).CHCl.CH:NPh$ HCl. Recently, in connection with the prepn. of imide chlorides from chloroacetanilides with substituents in the *o*-position to the N (*C. A.* **24**, 2999), similarly bright yellow compds. were obtained, and although analysis showed they were formed by loss of 1 mol. HCl from 2 mols. imide chloride the difference in color between the AcOH and $ClCH_2CO_2H$ derivs. was too great to be explainable on the basis of the amidine structure for both. A more thorough study has now shown that I is indeed a HCl salt of a colorless base $C_{16}H_{12}N_2Cl_2$ (II) which when heated with mineral acids under pressure splits off only 1 mol. $PhNH_2$; on less-energetic treatment with concd. HCl it yields a weakly basic substance $C_{10}H_6NCl_3$ (III) and on more vigorous treatment a phenolic compd. $C_{10}H_6(OH)NCl_2$ (IV) which regenerates III with PCl_5. III with HI and P loses all its Cl and gives pure quinaldine. The imide chlorides derived from the chloroacetarylides therefore condense with 2-fold elimination of HCl to give, not amidines like the acetarylides, but quinolines. It has thus far been impossible to force the PCl_5 reaction with $ClCH_2CONHPh$ in the amidine direction and that with AcNHPh in the quinoline direction. Derivs. of $EtCO_2H$ and $PhCH_2CO_2H$ also yield quinolines. The new reaction should prove to be one of the

most fruitful for the prepn. of quinolines, for the ring formation takes place very readily and in part quantitatively and the products can undergo numberless further transformations. *2-Chloromethyl-3-chloro-4-anilinoquinoline-HCl* (I), decomps. 222° (B. and W. give 212°), is obtained in 90–5% yield from $ClCH_2CONHPh$, cooled in running H_2O, treated with 1 mol. PCl_5, allowed to stand 12 hrs. and washed with Et_2O; the free *base* (II), m. 134°, is obtained by taking I up in a little cold C_5H_5N and quickly pptg. the II with dil. NH_4OH or Na_2CO_3. The course of the reaction of II with aq. HCl under pressure depends on the length of heating, the temp. and the amt. of HCl, for not alone is the NHPh group replaced by Cl and the latter by HO but the Cl in the CH_2Cl side chain can independently be replaced by HO. The *2-chloromethyl-3-chloro-4-hydroxyquinoline* (IV), m. 303°, is obtained in about 80% yield from II and 4 parts concd. HCl heated 12 hrs. at 160–5° and 1 hr. at 175–80°; it dissolves only in excess of concd. acid and is repptd. by diln. with H_2O. Along with the IV is formed the alkali-insol. III, the amt. of which is the greater the shorter the length of heating (46% each of III and IV after 14 min. at 170–80°). With only 1.5 parts by wt. of concd. HCl at 165°, II gives 77% IV and the H_2O-sol. *2-hydroxymethyl-3-chloro-4-hydroxyquinoline*, m. 283°, readily obtained by boiling IV several hrs. with aq. alkali. The *2-chloromethyl-3,4-dichloroquinoline* (III), m. 119–20°, is readily obtained by heating IV a few min. at 130–40° with somewhat more than 1 mol. PCl_5 and a little $POCl_3$. The 4-Cl and still more the Cl atom in the side chain are reactive and therefore heating III in aq. alc. a few hrs. with 1 mol. alkali gives the alkali-insol. *2-hydroxymethyl-3,4-dichloroquinoline*, m. 44°, $b_{0.2}$ 150–4°. The compd. obtained by Bischoff and Walden from I with Zn dust and AcOH, which they believed to have the compn. $C_{16}H_{15}N_2Cl$, is in reality *3-chloro-4-anilinoquinaldine;* it is best obtained from II with excess of Sn and concd. HCl on the H_2O bath and m. 172°; *picrate*, yellow, m. 229°. *3-Chloro-4-hydroxyquinaldine*, from IV in much boiling AcOH with 10 parts Zn dust, m. 340°, converted by PCl_5-$POCl_3$ into *3,4-dichloroquinaldine*, m. 322°. With 30 atoms Na and alc. II yields *py*-tetrahydroquinaldine, b_{12} 125°. Short warming of II with aq. alc. KOH gives *2-hydroxymethyl-3-chloro-4-anilinoquinoline*, m. 93–4°; with KCN in aq. alc. is obtained the *2-cyanomethyl compd.*, m. 156°, which readily condenses with BzH in alc and a few drops of alkali to form a *compd.* $C_{24}H_{16}N_3Cl$, yellow, m. 192°. With $PhNH_2$, II gives *2-anilinomethyl-3-chloro-4-anilinoquinoline*, m. 192°, isolated as the yellow *HCl salt*, and acetylated on the new N atom by hot Ac_2O, giving an *Ac deriv.* m. 209° With 3 mols. $NHMe_2$ in alc. II gives *2-dimethylaminomethyl-3-chloro-4-anilinoquinoline*, $b_{0.2}$ 215–20°, m. 93°; *picrate*, m. 190–3°; with 24 atoms Na and alc. the base gives $PhNH_2$ and *2-dimethylaminomethyl-py-tetrahydroquinoline*, yellowish, b_{15} 148–52°. *2-Dimethylaminomethyl-3,4-dichloroquinoline*, similarly obtained from III, m. 62°, *picrate*, red-yellow, m. 177°. *2-Piperidinomethyl-3-chloro-4-hydroxyquinoline*, from IV, m. 233–5°, sol. in both acids and alkalies. II and III also react with tertiary bases through the reactive CH_2Cl group. II with C_5H_5N gives the quaternary *compd.* $C_{21}H_{17}N_3Cl_2$, deep yellow, m. 245°; *isoquinoline compd.*, $C_{25}H_{19}N_3Cl_2$, m. 258°. Both give with aq. alkali slimy ppts. of the corresponding pseudo bases which, when fresh, redissolve in HCl to form the original salts but undergo change on standing. The yellow *compd.* $C_{18}H_{17}N_2Cl_3$, m. 272°, obtained by Bischoff and Walden from *p*-$MeC_6H_4NHCOCH_2OH$ and PCl_5, is readily obtained from *p*-$MeC_6H_4NHCOCH_2Cl$. *N*-(*Chloroacetyl*)-*p-iodoaniline*, m. 193°, likewise gives with PCl_5 a yellow magma which, pptd. from cold C_5H_5N with dil. Na_2CO_3, yields the *di-I analog*, $C_{16}H_{10}N_2Cl_2I_2$, of II, m. 184° (*HCl salt*, yellow, m. 232°; *picrate*, m. 202°); *2-diethylaminomethyl compd.*, $C_{20}H_{20}N_3ClI_2$, faintly yellow, m. 152° (*picrate*, yellow, m. 178°). *m*-$ClC_6H_4NHCOCH_2Cl$ gives practically only 1 *product*, $C_{16}H_{10}N_2Cl_2$, m. 179°, reacting smoothly with *p*-$EtOC_6H_4NH_2$ to form *2-p-phenetidinomethyl-3-chloro-4-m-chloroanilino-7-chloroquinoline*, m. 131°. Likewise, 3,4-$ClMeC_6H_3NHCOCH_2Cl$ gives a practically homogeneous *quinoline* $C_{18}H_{14}N_2Cl_4$, m. 174°. These results with $PhNH_2$ and its *m*- and *p*-substituted derivs. showed that the compds. recently isolated in very small amounts along with the imide chlorides from *o*-substituted chloroacetanilides are quinolines and not amidines. These compds. have the following m. ps.: from *o*-toluidine, 160°; *o*-anisidine, 196°, *o*-$ClC_6H_4NH_2$, 116°; *o*-$BrC_6H_4NH_2$, does not crystallize well (*HCl salt*, m. 135°). *2-Ethyl-3-methyl-4-anilinoquinoline-HCl*, from EtCONHPh and PCl_5 (yield, more than 50%), yellow, m. 217–20°; free *base*, m. 178°; *HCl salt*, yellow, m. 219–20°; *picrate*, m. 221°. The base heated 2.5 hrs. at 155° with 10 parts concd. HCl gives $PhNH_2$ and *2-ethyl-3-methyl-4-chloroquinoline*, m. 40–3°. If the temp. during the heating is raised to 180–90° there is obtained the *4-HO compd.*, only slightly sol. in alkalies but easily sol. in dil. mineral acids, m. 284°, converted back into the 4-Cl compd. by PCl_5-$POCl_3$ at 140° and reduced by Na-EtOH to the *py*-tetrahydro-2-ethyl-3-methyl-

quinoline, b_{12} 136–40° (HCl salt, m. 193°). *2-Benzyl-3-phenyl-4-anilinoquinoline-HCl* (80% yield), yellow, m. 209°; free *base*, m. 172°; *picrate*, m. 188°. Heated 6 hrs. at 170–200° with concd. HCl the 4-Cl compd. gives the *4-HO deriv.*, m. 308°. *2-Benzyl-3-phenyltetrahydroquinoline*, light yellow, $b_{0.3}$ 190–2°, non-volatile with steam.

C. A. R.

Azo compounds from trimethylmethyleneketopyrazine. VII. E. PRINCIVALLE. *Gazz. chim. ital.* **60**, 963–6(1930); cf. *C. A.* **24**, 3792.—2,5-Dimethyl-6-keto-1,6-dihydropyrazine couples easily with diazonium salts (cf. *C. A.* **23**, 3472), but if the formation of a lactimic group is prevented by substitution of the iminic H by a radical, no coupling takes place (cf. *C. A.* **24**, 3792). Azo compds. are also formed by the reaction of 1,2,4-trimethyl-5-methylene-6-keto-1,6,4,5-tetrahydropyrazine (I) (cf. *C. A.* **24**, 1383) and diazonium salts, since diazonium salts react easily with compds. which contain multiple aliphatic bonds (cf. Meyer, *C. A.* **14**, 1330; Quilico, *C. A.* **23**, 597, 3675). The reaction takes place by addn. to the $C:CH_2$ group, with subsequent elimination of H_2O thus: $OC\langle NMe.CMe:CH\rangle NMe.C:CH_2$ (I) + $PhN:NOH \longrightarrow -NMe.C(OH)CH_2N:NPh \longrightarrow -NMe.C:CHN:NPh$. I reacts also with $PhHNNH_2$ (II), with formation of the same azo compd. as that by the action of PhN:NCl, and the reaction takes place in a similar way. The basic products are stable compds., in general of an intense red color, and with H halides form salts; the structure is not certain (see later). I and II (equimol. quantities) heated in 20% AcOH for 48 hrs. at 50°, cooled, neutralized with NaOH, and the product recrystd. from EtOH, yields *1,2,4-trimethyl-5-phenylazomethylene-6-keto-1,6,4,5-tetrahydropyrazine* (III), red, m. 201° (decompn.). A better yield of III is obtained with PhN_2Cl though the procedure is more tedious, *i. e.*, sufficient NaOH is added to 1,2,5-trimethyl-6-keto-1,6-dihydropyrazine-MeI soln. to liberate the base, the mixt. is cooled, PhN_2Cl (calcd. quantity) is added dropwise, the product is let stand until sepn. is complete, the ppt. (a mixt. of III-HCl and IV) recrystd. from dil. HCl, decompd. with NaOH, and the III recrystd. from EtOH, dil. HCl or dil HI. III and dil. HI allowed to crystallize yield the *HI salt* $C_{14}H_{17}ON_4I$ (IV), red, m. 228° (decompn.). By the same procedure as in the previous prepn., there is obtained from *p*-$MeC_6H_4N_2Cl$, after recrystn. from EtOH, *1,2,4-trimethyl-5-p-tolylazomethylene-6-keto-1,6,4,5-tetrahydropyrazine* (V), red, m. 214° (decompn.). V and dil. HI yield the *HI salt* $C_{15}H_{19}ON_4I$ (VI), brilliant green, m. 226° (decompn.). Likewise from V and dil. HCl is obtained the *HCl salt*, $C_{15}H_{19}ON_4Cl$ (VII), green, m. 205° (decompn.). The salts IV, VI and VII may have either or both of two structures, *viz.*, $OC.NMe.CMe:CH.NHMeI.C:CHN:NPh$ (VIII) or $OC.NMe.CMe:CH.NMeI:CCH:NNHPh$ (IX). VIII would be formed by the normal addn. of the halogen acid, with conversion of N from tervalent to quinquevalent. IX would be formed from VIII by subsequent isomerization. It is very probable that IX represents the form of IV, VI and VII, which means that they have a structure analogous to those formed from 2,3,3-trimethylindolenine-MeI (cf. Rosenhauer and Feilner, *C. A.* **21**, 407). Further expts. are in progress to settle this problem.

C. C. DAVIS

Strychnos alkaloids. LVII. Oxidation of tetrahydrostrychnine and some derivatives. HERMANN LEUCHS (IN PART WITH FRITZ KRÖHNKE). *Ber.* **63B**, 3184–9(1930); cf. *C. A.* **25**, 705.—Whereas in the oxidation of brucine, the aminostrychnines, strychnine and strychnidine (I) by CrO_3 only products which had been attacked in the C_6H_4 nucleus could be isolated, the oxidation of tetrahydrostrychnine (II) proceeded differently. While here, too, there was obtained a *compd.* $C_{17}H_{20}O_4N_2$ (III), analogous to diketonucidine, isolated in 7.4% yield as the perchlorate, there was also obtained 14% of an amino acid $C_{21}H_{32}O_4N_2.4H_2O$ (IV), whose compn. shows that the C_6H_4 nucleus is still intact. IV had already been observed in the oxidation of I, but in such small and widely varying yields that its formation was probably due to the presence of II in the crude I. The oxidation of the II consists in the taking up of two O and loss of four H atoms; since a CO_2H group is formed, there may have occurred the change $CH_2(OH)$ into CO_2H, with which would have to be related that of $-CH_2.NH-$ into $-CO.NH-$ or $-C(OH):N-$. For in strychninic acid, with the same groups $-CH_2.NH-$ and HO_2C-, these are anhydrized by mineral acids. The negative semicarbazone test would indicate that the compd. is not a ketone. Oxidation of a (b):$N.CH_2-$ residue would still leave a salt-forming group in (a):NH.CH= but would not explain the lactam ring remaining open. To test these views, the Ac derivs.

of II were studied. The *O,N*-di-Ac deriv. (V) is quite stable toward CrO_3; it consumed less than 19 equivs., giving chiefly, with loss of the *O*-Ac group, an *amino acid* $C_{23}H_{28}O_4N_2$ (VI), isolated as the perchlorate in 55% yield. From the compn. of VI, the reaction must have been limited to sapon. and conversion of $—CH_2(OH)$ into $—CO_2H$, *i. e.*, VI must be *N*-acetylstrychninic acid; attempts to prep. it from Ac_2O and an alk. soln. of the acid gave only strychnine. The sapon. precedes the oxidation, and the *N*-Ac deriv. likewise gives VI (in 77% yield, with only 14 equivs. CrO_3); 10 equivs. KMnO in Me_2CO at 0° gave no cryst. products. Attempts to oxidize II with Br gave first an aromatic *di-Br deriv.* (*o*, *p* to the (a)N) (VII) which then changed into resinous substances. *Perchlorate* of I, needles and prisms with 1 H_2O, $[\alpha]_D^{17}$ —10.1°/d. (H_2O); HCl salt, $[\alpha]_D^{17}$ —13.5°/d. *Perchlorate* of II, $[\alpha]_D^{15}$ —74.9°/d.; HCl salt, $[\alpha]_D^{15}$ —86.6°/d.; free base, needles with 2 H_2O, m. 202° (vacuum); *N*-Ac deriv., prisms with 1 H_2O, m. 157–9° and, anhyd., 197–9° (vacuum); *perchlorate*, $[\alpha]_D^{15}$ 104–6°/d.; HCl salt, $[\alpha]_D^{15}$ 122.3°/d. V, tables and prisms with 1 H_2O, m. around 100° and, anhyd., 135–42° $[\alpha]_D^{15}$ in 1 mol. 0.1 *N* HCl 112.2°/d.; *perchlorate*, prisms with 1.5 H_2O, $[\alpha]_D^{15}$ 96°/d VII, sinters 238°, m. 248–50° (250–2° *in vacuo*), shows no basic reactions and does not react with $FeCl_3$, dissolves in CrO_3–H_2SO_4 with red-violet color, is unchanged by boiling $Ba(OH)_2$; *HBr salt*, needles losing 10.1% in wt. at 100° and 15 mm.; *HCl salt*, $[\alpha]_D^{15}$ —23.2°/d. IV, needles or leaflets with 4 H_2O (erroneously given as 3 H_2O in an earlier paper (*C. A.* **25**, 705)), sol. in *N* $KHCO_3$ but not in *N* NaOAc, does not m. 320°; HCl salt, $[\alpha]_D^{15}$ —24.0°/d. *Perchlorate* of III, tables and octahedrons with 2 H_2O, $[\alpha]_D^{15}$ 73.8°/d.; free *base*, faintly yellow prisms, losing (under 15 mm.) 1.5% in wt. at 75° and 2.3% at 115°, sinters 230°, m. 243–5° (245–7° *in vacuo*). Oxidation with 24 equivs. CrO_3 gave more than 10% IV and less than 5% salt of III; pretreatment of the II with $FeNH_4(SO_4)_2$ decreased the yields. *Perchlorate* of IV, $[\alpha]_D^{20}$ 118.5°/d. (H_2O), free *acid*, prisms with neutral reaction, sinters 180–200°, becomes foamy 220°, decomps. 305°. C. A. R

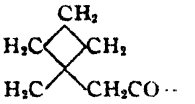
Sinomenine and disinomenine. XXIII. The identity of β-tetra-hydrodesoxy-codeine and dihydrothebacodine. KAKUJI GOTO AND SHINGO MITSUI. *Bull. Chem. Soc. Japan* **6**, 33–9(1931).—Kondo and Ochiai (*C. A.* **24**, 3243) obtained desoxytetra-hydrosinomenine, the *d*-form of dihydrothebacodine (I), by Clemmensen reduction of sinomenine (II) whereby the phenolic OH group is apparently removed and the CO group reduced to a secondary alc. Goto (*C. A.* **24**, 1385) attempting to repeat this obtained desoxydemethoxydihydrosinomenine (III), the *d*-form of β-tetrahydrodesoxy-codeine (IV). The retention of the phenolic OH and reduction of the CO group to CH_2 is now confirmed by reduction of demethoxydihydrosinomenine to III by means of PCl_5 and subsequent catalytic reduction of the ketone dichloride. By subjecting various derivs. of II to the Tafel electrolytic reduction G. and M. were able in no case to remove the phenolic OH and obtain an alc. base corresponding to the dihydrothebacodine of Speyer and Siebert. The identity of I and IV is further supported by the identity of the des-*N*-Me bases, m. 147–8°, and the N-free bases, m. 107–8°, from both sources. It is proposed to substitute the name *dihydro-eu-thebainan* for K. and O.'s *dihydrothebainan*, designating I, III and IV. The easy reduction by the Clemmensen method of the MeO and corresponding OH groups in all derivs. of I contg. the CO group makes it seem probable that these groups are vicinal. R. C. ELDERFIELD

The sapogenin of guaiac bark. I. E. WEDEKIND AND W. SCHICKE. *Z. physiol. Chem.* **195**, 132–8(1931).—The crude saponin was hydrolyzed with 5% H_2SO_4 and the insol. amorphous end sapogenin, for which the name *guagenin* is proposed, was used in the prepn. of derivs. Ac_2O converted it into a cryst. *acetylguagenin*, m. 268°, $[\alpha]_D^{17}$ in $CHCl_3$ 74.5°, from which the *Me ester*, m. 220°, $[\alpha]_D^{17}$ in $CHCl_3$ 69.2°, was obtained by treatment with CH_2N_2. By sapong. the Ac deriv. with KOH in MeOH the *guagenin*, $C_{30}H_{48}O_3$, m. 310°, was obtained cryst. This cryst. product yielded a *Me ester*, m. 196°, $[\alpha]_D^{17}$ 73.9°, and an Ac deriv. identical with that prepd. from the amorphous sapogenin A. W. DOX

Synthetic experiments on the constitution of the bile pigment. III. Synthesis of hydroxypyrromethenes, and some derivatives of coproporphyrin I. HANS FISCHER AND WALTER FRÖWIS. *Z. physiol. Chem.* **195**, 49–80(1931); cf. *C. A.* **18**, 2515.—A study was first made of the reactivity of the α-Br in 4,3′,5′-trimethyl-3,4′-dipropionic acid-5-bromopyrromethene and its Me ester (I), since a replacement of the Br by OH should yield a product very closely related to xanthobilirubic acid. I reacts with $PhNH_2$ to form *4,3′,5′-trimethyl-3,4′-di(propionic Me ester)-5-phenylaminopyrromethene-*

HBr, m. 186°. The *free base*, m. 145°, forms a *complex Cu salt*, m. 120°. Treatment of I with $MeNH_2$ does not replace the Br but converts the ester groups into the corresponding amide, yielding *4,3',5'-trimethyl-3,4'-di(propionic methylamide)5-bromopyrromethene* (II), m. 212° (decompn.). A similar reaction occurs with NH_3 in MeOH, which yields *4,3',5'-trimethyl-3,4'-di(propionamide)-5-bromopyrromethene*, decomps. 260–70°. Treatment of II with 10% KOH in MeOH replaces the Br by MeO, forming *4,3',5'-trimethyl-3,4'-di(propionic methylamide)-5-methoxypyrromethene*, m. 225°. I yields a similar MeO deriv., *viz.* *4,3',5'-trimethyl-3,4'-di(propionic Me ester)-5-methoxypyrromethene* (III), m. 88°. The OH deriv. representing hydrolysis of the Br in I, *viz.*, *4,3',5'-trimethyl-3,4'-di(propionic Me ester)-5-hydroxypyrromethene*, m. 180°, may be prepd. directly from I by heating the AcOH soln. with AgOAc, or from III by hydrolysis of the MeO. This is accomplished by heating III with MeONa at 170–80° and reësterifying the carboxyls with Me_2SO_4, or better by resorcinol fusion of III at 170–80°. This hydroxymethene in $CHCl_3$ gives a green color reaction with diazobenzenesulfonic acid and HCl. Heated to 170–80° with HBr-AcOH, 2 mols. condense to coproporphyrin in small yield. The di-Et deriv. corresponding to the free acid of I, when heated with KOH in MeOH, yields *4,3',5'-trimethyl-3,4'-diethyl-5-methoxypyrromethene*, m. 70°, from which *4,3',5'-trimethyl-3,4'-diethyl-5-hydroxypyrromethene*, m. 243°, is obtained in small yield by resorcinol fusion. The mother liquors remaining from the prepn. of the HBr salt of I (free acid), when evapd. spontaneously over a period of several months, gradually formed coproporphyrin I, which was isolated and identified as the tetra-Et ester, m. 226°. In the prepn. of coproporphyrin tetra-Me ester by citric acid fusion a mother liquor remained from which the Me ester of coproporphyrin IV, m. 177°, was isolated. Porphyrin formation occurs also in small yield when the HBr salt of the free acid of I is treated with H_2SO_4. Coproporphyrin tetra-Me ester I and isouroporphyrin octa-Me ester II yield *complex Co salts*, m. 270° and 316°, resp. The copro ester gives a *Ag salt*, m. 286°, which may be sapond. to the free acid by boiling with KCN in 90% EtOH and reësterified by shaking with Me_2SO_4 and Na_2CO_3. Treatment of the Ag salt ester with $Fe(OAc)_2$ and AcOH contg. a little NaCl replaces the Ag by Fe, yielding the tetra-Me ester of coprohemin, m. 245°. Na_2CO_3 converts the latter into coprohematin tetra-Me ester, m. 215°. Reduction of this ester with Na and AmOH converts it into the corresponding *chlorintetracarboxylic acid* which dissolves in Et_2O to a stable green soln., but its alk. soln. soon reverts to the red porphyrin. Exposure of an aq. colloidal suspension of coproporphyrin to summer sunlight for several days converts it into a chlorin which differs from the synthetic chlorin in that its alk. soln. is stable to atm. O. Nitration of the copro ester with concd. HNO_3 yields a *dinitrocoproporphyrin*, and hematinic anhydride as a by-product. This dinitro deriv. forms a *tetra-Me ester*, m. 191° (*complex Cu salt*, m. 200°, *complex Ag salt*, m. 240°). If the esterification is performed by refluxing with 5% HCl in MeOH the product is a *mononitrodihydroxyporphyrin ester*, m. 206° (*complex Cu salt*, m. 245°). Attempts to prep. an aminoporphyrin by reduction of the NO_2 were unsuccessful. After treatment of the dinitro deriv. with Na-Hg the products isolated were coproporphyrin, dinitroporphyrin, and *mononitroporphyrin*, from which a *tetra-Me ester*, m. 204°, was prepd. The mono- is more stable than the dinitro deriv. and can be esterified at refluxing temp. Finally a *tetrahydrazide*, was prepd. from the tetra-Me ester of coproporphyrin and $N_2H_4 \cdot H_2O$ in MeOH. Its *Fe salt* was obtained in the same manner from coprohemin ester. The *tetraazide of coproporphyrin* was prepd. by treatment of the hydrazide with $NaNO_2$ and HCl with ice cooling. It explodes at about 90°. MeOH converts the azide into a *tetraurethan*, m. 190°. This is a remarkably stable substance, not attacked by concd. H_2SO_4 or by resorcinol fusion at 200°. It is apparently sapond. by HCl at 200°, but the expected tetraaminoporphyrin could not be isolated in a pure state.

A. W. Dox



Blossom xanthophylls. The pigment of the sunflower. L. Zechmeister and P. Tuzson. *Ber.* **63B**, 3203–7(1930).—The polarimetric method is at present probably the most reliable means of distinguishing closely related pigments of the xanthophyll type from each other. The non-homogeneity of leaf xanthophyll was proved by the isolation of analytically pure prepns. of widely varying rotations (137–92°) from stinging nettles; the maize pigment, zeaxanthin, can readily be distinguished from the xanthophyll of leaves by its *l*-rotation, and the lutein of egg yolk by its characteristically low *d* rotation (72°). In the search for other natural xanthophylls differing in rotation from that of leaves, it has been found that the well-crystd. pigment (I) of the sunflower (*C. A.* **25**, 314) has a low *d*-rotation (75°) identical, within the exptl. errors, with that of the egg lutein, and as its other consts. also agree with those of lutein, there can hardly be any doubt that the two substances are identical. The sunflower

seems to contain the lutein mostly in the form of a cryst. ester. The I (0.234 g. from 300 g. dried petals) was isolated by letting the fresh petals stand 1 day under 90–5% EtOH, drying at 35°, powdering, percolating with C_6H_6, concg. *in vacuo* at 40°, adding 98% alc. (which ppts. a colorless substance), filtering, adding H_2O, extg. with Et_2O, letting the washed Et_2O ext. stand 20 hrs. with concd. KOH in MeOH, concg. the Et_2O layer (dried with Na_2SO_4) *in vacuo* in a current of CO_2, pptg. with petroleum ether, extg with boiling 70% EtOH and crystg. the insol. residue from MeOH. It m. 193° (cor.) $[\alpha]_C^{18}$ 75° ($CHCl_3$), spectrum in 96% EtOH (5 mg. in 1 l., 10-mm. layer), 486–72, 455.5 442.5, about 420. C. A. R.

The iron salt of pheophorbide *b*. Otto Warburg. *Ber.* **64B**, 682–3(1931).—A mixt. of 1 g. Fe powder, 1 g. NaCl and 60 cc. glacial AcOH is boiled in an atm. of CO_2, cooled and filtered. The Fe salt of pheophorbide *b* is obtained in 520 mg. yield by adding 1 g. pheophorbide *b* to the above soln., passing a current of CO_2 through it and heating for 10 min. on a water bath. The crude product deposited on cooling is centrifuged and washed with 50% AcOH and H_2O. It may be crystd. by dissolving 100 mg in 15 cc. hot propionic acid, filtering and adding 7.5 cc. hot 0.5% HCl. The crystals which sep. on cooling are probably $(CH_3CH_2CO)C_{31}H_{32}N_4O_6FeCl$. The Fe salt of pheophorbide *a* may be similarly prepd. Ruth Berggren

Isolation of phytosterolin from wheat embryo. Nobuzo Nakamura and Akiyoshi Ichiba. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, Nos. 289–91, 137–41(1931).—From the ether ext. of wheat embryo 0.2% of phytosterolin was isolated It is identical with the glucoside ipuranol of phytosterol from other materials (*C. A.* **7**, 2218). It forms needles (from AmOH), m. 285–90°. *Ac deriv.* m. 168°, $[\alpha]_D$ −22.4° (in $CHCl_3$). *Bz deriv.* m. 198°, $[\alpha]_D$ 17.24° (in $CHCl_3$). Alfred Burger

Some relations between constitution and odor. A. Angeli. *Gazz. chim. ital* **60**, 939–46(1930).—In view of the odorous characteristics of aromatic musks and of violet ketones, it is surprising that the ketones first synthesized by Ruzicka possess such remarkable odors, for they contain no Me groups around the CO residue Consequently, because of the size of the ring resulting from a great no. of methylene groups, deformation of the ring itself probably occurs in such a way that lateral nodes are formed. These nodes are made up of residues which function in the same way as do the Me groups in the musks and ketones mentioned In this case there would be a twisting as represented by the structure:

and this seems likely from the fact that, though x-ray examn. of the ketones of Ruzicka furnish no evidence, Lee (cf. *C. A.* **21**, 3189) has noticed anomalies in certain long-chain compds. which are greatest with 15 C atoms. Furthermore Lee and van Rysselberge (cf. *C. A.* **24**, 59) suggest a spiral form in long-chain compds. To throw light on this problem, the chem. behavior of some cyclic ketones was studied, particularly the influence of certain substituents (alc. radicals) on the reactions which are characteristic of these ketones. If the hypothesis already suggested, *i. e.*, that in proximity to the CO group the methylene chain is deformed, were true, then it is probable that the condensations mentioned take place only partially or not at all. The cycloketone contg. 15 atoms (with the com. name of hexalthone) was mixed with BzH (equimol quantities) and condensation was attempted with cold, dil. KOH, hot aq. KOH (as with cyclohexanone) and with alc. KOH. There was no condensation in any case Moreover as in expts. of Wieland (no reference) hexalthone (1 mol.) and then (cooling with ice) $EtNO_2$ (1 mol.) were added to EtOK (1 mol.) in abs. EtOH, and the next day Et_2O was added, but no salt sepd., and upon the adds. of water all the hexalthone was recovered. This behavior makes it probable that there is a steric hindrance at work, which would in turn support the hypothesis suggested. Very probably the same arguments apply to polymethylenic lactones, *e. g.*, ambrettolides, which have been studied by Kerschbaum. The exptl. details of the present paper will be published later. Cf. *C. A.* **24**, 4525. C. C. Davis

Organic compounds. I. G. FARBENIND. A.-G. (Otto Nicodemus and Walter Berndt, inventors). Ger. 514,174, Sept. 16, 1925. Addn. to 481,819 (*C. A.* **24**, 2139). Org. compounds are obtained by leading the vapors of mixed aromatic-heterocyclic ketones, optionally in the presence of oxidizing agents and catalyzers, over highly porous materials. Thus, 2-xylyl-5-xyloylpyridine is evapd. under reduced pressure in an air current and passed over active C at 400–420°. The substance 1-xylyl-7-methylbenzoquinoline (m. 170°) is found among the unchanged starting material and other products. Other examples are given.

Hydrocarbons. I. G. FARBENIND. A.-G. Fr. 695,125, May 6, 1930. Products of higher b. p. are prepd. by treating satd. compds. of the aliphatic or hydroaromatic series, particularly the halogen derivs., with hydrocarbons of the C_2H_4 or C_2H_2 series under pressure and in the presence of condensing agents. Thus, hydrocarbons distg. between 120° and 200° are prepd. from C_2H_4 and MeCl in the presence of $AlCl_3$, and a product distg. between 150° and 180° contg. about 2% of O from the double compd. of Et_2O and BF_3 under pressure of C_2H_4. Cf. *C. A.* **25**, 1536 and following abstrs.

Hydrocarbons. I. G. FARBENIND. A.-G. Fr. 37,296, Aug. 1, 1929. Addn. to 663,539. In the process of the prior patent the conditions of working in the second or following phases are made more vigorous otherwise than by a rise of temp., *e. g.*, by an increase of pressure, an increase of the partial pressure of H, the use of a more active catalyst, etc., or these measures are used along with a rise of temp. (cf. *C. A.* **24**, 2875).

Hydrocarbons. I. G. FARBENIND. A.-G. Fr. 37,440, Sept. 17, 1929. Addn. to 650,583 (*C. A.* **23**, 5312). The S and O compds. are eliminated from the starting materials by heating these in the presence of catalysts and, if necessary, gases other than H or treating the starting materials with appropriate solvents or in any other manner.

Diolefins. PAUL FEILER (to I. G. Farbenind A.-G.). U. S. 1,795,549, March 10. In the recovery of diolefins such as butadiene from various mixed gases contg. the diolefins, the gas is treated with a salt of a heavy metal from groups 1 and 2 of the periodic system such as Cu_2Cl_2 or $AgNO_3$ and the diolefins are subsequently liberated (suitably by heating) from the resulting additive compds.

Organic oxygen compounds. I. G. FARBENIND. A.-G. Fr. 37,351, Aug. 16, 1929. Addn. to 646,087 (*C. A.* **23**, 2186). Benzene hydrocarbons having a lateral chain bound cyclically to the C_6H_6 ring, particularly benzopolymethylenic compds. are oxidized by O or gases contg. O in the presence of catalysts, preferably heavy metals. Thus, tetrahydronaphthalene is oxidized to α-ketotetrahydronaphthalene and α-hydroxytetrahydronaphthalene. Several examples are given.

Oxygenated organic compounds from carbon oxides and hydrogen. H. DREYFUS. Brit. 338,854, July 24, 1929. Products such as EtOH, PrOH, acetaldehyde, HOAc, MeOAc and their higher homologs, and ketones, are formed from mixts. contg. C oxides and H such as water gas, coke-oven gas or producer gas in the presence of catalysts consisting of alkali or alk. earth or Cu silicates, borates or phosphates or salts of oth[illegible]xyacids of P. Temps. of 200–600° and pressures of 50–500 atm. may be used,

CH_4 or inert gases such as N may be present and reaction chambers of Cu or steel lined with Cu or of steel contg. Mo, W, Mn, Co or Ni may be used. Cf. *C. A.* **25**, 1839.

Mixtures of hydrogen and carbon monoxide. Maria Casale-Sacchi. Austrian 121,228, Sept. 15, 1930. Hydrocarbons are treated with O and an excess of steam at a temp. above 1000° under reduced pressure.

Oxidizing organic substances. Consortium für elektrochem. Ind. G. m. b. H. (Erich Baum and Willy O. Herrmann, inventors). Ger. 518,391, May 7, 1924. A mixt. of the org. substance to be oxidized and an oxygen-contg. gas or other oxidizing agent is caused to flow rapidly through a narrow orifice and impinge on a heated surface, which may consist of, or contain, a catalyst. The oxidation of AcH, C_4H_2 and MeOH to CH_2O, of C_6H_6 to maleic acid, and of $C_{10}H_8$ to phthalic acid or phthalic anhydride is referred to. Examples are given.

Recovering organic substances from adsorbent materials. I. G. Farbenind. A.-G. Fr. 695,123, May 6, 1930. Org. substances are recovered from adsorbent materials contg. them by heating them with water, or aq. solns. or other org. or inorg. liquids in which the org. substances are scarcely or not at all sol. in the presence of substances which are more easily wetted by the org. substances than the adsorbent materials which contain them. Thus fuller's earth contg. oil is mixed with active C and soft soap and the mass is boiled with water. An oily layer contg. the C seps., and the C is removed by filtration.

Hydrocyclic compounds. I. G. Farbenind. A.-G. Fr. 37,498, Oct. 9, 1929. Addn. to 663,564 (*C. A.* **24**, 625). Hydrocyclic compds. are prepd. by condensing unsatd. α,β-nitriles contg. the atomic group $-C=C-C\equiv N$ in the form of a chain, with compds. contg. doubly conjugated $C=C$ compds. Thus, the nitrile of crotonic acid ($CH_3CH:CHC:N$) is heated under pressure with cyclopentadiene. The product has probably the formula $CH:CH.CH.CHMe.CH(CN).CH.CH_2$. With 2,4-dimethyl butadiene, a product of the formula $CH_2.CHMe.CH(CN).CHMe.CH:CMe$ is obtained. Products from the nitrile of sorbic acid are also described.

Basic products. I. G. Farbenind. A.-G. Fr. 37,289, July 30, 1929. Addn to 671,362 (*C. A.* **24**, 2244). Imido ethers, the acids from which they are derived, their chlorides, esters or amides are condensed with primary or secondary aromatic amines contg. a basic lateral side chain with a tertiary N, or the side chain with a tertiary N may be introduced afterward. Thus, if *p*-β-diethylaminoëthoxyaniline is condensed with oleic acid chloride a product of the formula $C_{17}H_{33}CONHC_6H_4OC_2H_4NEt_2$ is obtained. Other examples and the formulas of the products obtained are given. Cf. *C. A.* **25**, 837, 1261.

Diaryl compounds. Federal Phosphorus Co. Fr. 37,449, Sept. 20, 1929. Addn. to 667,840 (*C. A.* **24**, 1394). Complex diaryl compds. of b. p. higher than biphenyl are produced by vaporizing the corresponding hydrocarbon, *e. g.*, pure com benzene or com. 90% benzene contg. aromatic hydrocarbons other than C_6H_6 such as toluene and xylene. The preliminary heating is to a temp. just below that at which diaryl compds. are formed and the temp. is then rapidly raised to that at which these compds. are formed.

Complex diaryl compounds. J. N. Carothers, T. J. Scott and Federal Phosphorus Co. Brit. 338,631, Sept. 5, 1929. See preceding abstr.

Drying organic liquids. Wilhelm Kopeska. Austrian 120,875, Aug. 15, 1930. Benzine and other org. liquids contg. water in suspension are dried by treatment with a higher fatty acid ester of a carbohydrate of the formula $(C_6H_{10}O_5)_n$. The ester must be insol. in the org. liquid, and may be used in such a form that the org. liquid can filter through it. Cellulose stearate, palmitate and laurate are suitable esters.

Trichloroalcohols. Chemische Fabriken Joachim Wiernik & Co. A.-G. (Gustav Heilner, inventor). Ger. 515,539, Jan. 14, 1925. The corresponding ketone is caused to react with acid. The alkali amide may be suspended in a water-free indifferent solvent. Thus, acetone and $CHCl_3$ are added to a suspension of $NaNH_2$ in Et_2O. The temp. is kept at 0°. Dil. H_2SO_4 (33%) is added and a steam distn. gives a 60% yield of $C_4H_7Cl_3OH$. Further examples are given.

Hydrogenating paraldol. I. G. Farbenind. A.-G. Brit. 338,807, Jan. 30, 1929. 1,3-Butylene glycol is made by catalytic hydrogenation of paraldol at 30–50° in the presence of a solvent or diluent such as water, EtOH, isopropanol or butanol, under

pressure, with catalysts such as Ni or Cu or both on pumice or kieselguhr. Use of Co, Pt and Pd also is mentioned.

Ketones such as acetone. H. DREYFUS. Brit. 338,518, Aug. 19, 1929. The vapors of aliphatic alcs. contg. at least 2 C atoms, in admixt. with air or O, are subjected to temps. of 250–700° in the presence of catalysts such as oxides, hydroxides, carbonates, metaborates, ortho-, meta- and pyro-phosphates and silicates of Ca, Ba or Mg which may be deposited on pumice or kieselguhr. Natural compds. such as wollastonite, augite, osteolite, danburite or datolite may be used, and the gases may be passed through a tube of Cu, Fe, "staybrite" or earthenware contg. the catalyst and the vapor of an aliphatic acid such as HOAc may be added and a large excess of O used. Brit. 338,519 relates to a similar process in which steam is added to the reaction mixt.

Carbocyclic ketones. Brit. 339,348, Oct. 9, 1928; Soc. anon. M. NAEF & CIE. Fr. 37,380, Aug. 30, 1929. Addn. to 599,765. Unsatd. cyclic ketones having more than 9 ring members are prepd. by submitting to the action of heat a metallic salt of an unsatd. dicarboxylic acid contg. at least 11 atoms of C in the normal chain and the 2COOH groups at the ends of the chain. Salts of UO_2, or metals having the at. numbers 59–72 are referred to.

Methylene ethers. IMPERIAL CHEMICAL INDUSTRIES, LTD., T. BIRCHALL and S. COFFEY. Brit. 338,624, Aug. 30, 1929. In the production of products such as methylene diethyl ether, methylene di-*n*-butyl ether and 1,3-dioxane, $(CH_2)_6N_4$ is caused to react with mono- or di-hydric alcs. in the presence of acids such as HCl or H_2SO_4. Among the alcs. which may be used for such reactions are: MeOH, EtOH, *n*-Bu alc., allyl alc., benzyl and substituted benzyl alcs., and ethylene and trimethylene glycols.

Diazo compounds from 4-aminoresorcinol. N. N. VOROZHTZOV. Russ. appl. 49,050, June 12, 1929. 4,1,3-$H_2NC_6H_3(OH)_2$ is diazotized by known methods in the presence of Cu or Fe salts or Co, Ni, Zn or other similar metal

Diazoamino compounds. I. G. FARBENIND. A.-G. Fr. 37,246, July 25, 1929. Addn. to 677,579 (*C. A.* **24**, 3248). Diazoamino compds. are made by the reaction of diazo compds. on polycyclic primary amines sol. in water, which on account of the position of the substituents, with respect to the amino group, are not capable of forming azo dyes. Thus, 3-nitro-4-amino-1-methylbenzene is diazotized and combined with 1-naphthylamine-2,4-disulfonic acid. Other examples are given.

Aromatic amines. I. G. FARBENIND. A.-G. (Julius Laux, inventor). Ger. 515,758, Aug. 21, 1925. Aromatic amines are prepd. by reducing the corresponding nitro compds. with Fe in the presence of aq. Al salt solns. Thus $PhNO_2$ is reduced to $PhNH_2$ by Fe in the presence of aq. $AlCl_3$. After distg. off the $PhNH_2$, a yellowish brown ppt. is left, which, on sepn. from the unused Fe, produces a deep violet-red Fe dye on heating to glowing. Further examples are given.

***N*-Aminoalkylamines.** I. G. FARBENIND. A.-G. (Werner Schulemann, Fritz Schonhöfer and August Wingler, inventors). Ger. 518,207, Jan. 26, 1927. Amines are caused to react with aminoalkyl halides or the corresponding sulfonates, the aminoalkylating agents being used in the form of their salts, in the presence or absence of an acid-binding agent and a solvent. Thus, ω-diethylaminoethylaniline may be prepd. by heating $PhNH_2$ with $Et_2NCH_2CH_2Cl.HCl$. Other examples are given also. Cf. *C. A.* **24**, 2469.

Esters. E. I. DU PONT DE NEMOURS & Co. Ger. 515,678, Mar. 25, 1928. Esters and other org. compds. result when primary alcs. with more than 1 C atom or a mixt. of alcs. are subjected to the action of dehydrogenating catalyzers at raised temp. and pressure. The alcs. are circulated over an equal amt. of catalyzer, volume-for-volume, at a pressure of 10 atm. The catalyzers may be Ni, Cu, Co, Fe alone or mixed with MnO_2, Cr_2O_3, MgO, CaO, etc. EtOH treated in this way gives 55% unchanged EtOH, 25% AcOEt, 12.5% BuOH and small quantities of AcOH, AcH, CO_2 and CH_4.

Lactic acid esters. SCHERING-KAHLBAUM A.-G. (Frank Hartwich, inventor). Ger. 518,388, Jan. 23, 1926. A mixt. of Mg lactate, an alc. and an acid, with or without a catalyst, *e. g.*, an excess of acid or $CaCl_2$, is heated. Examples are given.

Halogenated phosphorous and phosphoric esters. I. G. FARBENIND. A.-G. Brit. 338,981, Aug. 31, 1929. Reaction is effected between a compd. contg. an alkylene oxide group and a P trihalide or oxyhalide, suitably with use of a catalyst such as I, $FeCl_3$, S or iron filings. *E. g.*, with PCl_3 and ethylene oxide, the O bridge is opened and a Cl atom combines with a CH_2 group while the P atom combines with the O. Thus ethylene oxide can be attached up to three times, so that the neutral ω-chloroethyl ester of phosphorous acid may be formed. Examples are also given of reactions between epichlorohydrin and P oxychloride with iron filings as catalyst and of epichlorohydrin with PBr_3.

Alkyl halides. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 338,742, Jan. 8, 1929. Products such as pentyl, butyl and propyl chlorides and butyl bromide are made by chlorination or bromination of paraffin hydrocarbons such as propane, butane and pentane, as by mixing the reacting materials in the dark at a low temp. and then heating without exposure to light (suitably in app. of enameled metal or Pyrex glass).

Addition products from acetylene and hydrogen halides. CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit. 339,093, Nov. 19, 1928. Addn. products are formed by passing a mixt. of C_2H_2 and a halide such as HCl or HBr at a raised temp. over a catalyst comprising a compd. of an alk. earth metal, Mg, Bi, Sb, V, Zn, Al, Fe or Hg, or a mixt. of such compds., carried on a material of large surface such as active C or SiO_2 gel.

1-Aroylamino-4-haloanthraquinones. I. G. FARBENIND. A.-G. (Willi Hartmann, inventor). Ger. 518,406, Dec. 23, 1926. 1-Aroylaminoanthraquinones are halogenated in inert solvents. Examples are given.

Anthraquinoneazines. W. SMITH, S. G. WILLIMOTT, J. THOMAS and SCOTTISH DYES, LTD. Brit. 338,486, May 13, 1929. Anthraquinonetetrahydrodiphenazines are made by condensing α,α-dichloroanthraquinones with *o*-nitroaniline or α,α-diaminoanthraquinones with *o*-nitrochlorobenzene, and treating the products with alc. Na sulfide. The condensation may be effected by heating in an inert solvent such as $PhNO_2$ in the presence of an acid-absorbing agent such as Na_2CO_3 and a Cu catalyst, and the hydrodiphenazines may be converted into phenazines by treatment with oxidizing agents. Several examples are given.

Mercaptobenzothiazoles. I. G. FARBENIND. A.-G. (Eduard Tschunkur and Ernst Herdieckerhoff, inventors). Ger. 518,206, Feb. 22, 1928. See Fr. 669,921 (*C. A.* **24**, 1867).

Monoxanthogens. GEORGE S. WHITBY (to Roessler & Hasslacher Chemical Co.) U.S. 1,796,972, March 17. Monoxanthogens of the general formula RO—CS—S—CS—OR, wherein the group RO— is the radical of any aliphatic alc. or deriv. thereof capable of yielding a xanthate and wherein R is of a non-cyclic nature can be prepd. in excellent yield by the reaction of alkali metal cyanides with the corresponding disulfide compds as follows: RO.CS.S_2.CS.OR + MCN = RO.CS.S.CS.OR + MSCN (where M is an alkali metal). The disulfides used may be prepd. by a variety of methods, such as electrolysis of concd. xanthate solns., action of I with KI on a xanthate soln., etc., but preferably are prepd. through the action of an alkali metal hypochlorite on a xanthate. The propyl, butyl, isobutyl, isoamyl and hexyl derivs. are yellow oils, while the methyl deriv. forms yellow needles m. 55°. The monoxanthogens prepd. from a mixt. of higher alcs. (corresponding in mean mol. wt. to decyl alc.) as well as from the monoethyl ether of ethylene glycol, by way of the corresponding xanthates and dixanthogens, are also yellow oils. Those monoxanthogens in which R—O—, of the formula R—O—CS S.CS—O—R is a secondary aliphatic alc. radical, are good accelerators of the vulcanization of rubber and are called secondary alkyl monoxanthogens. As an example of this group the isopropyl deriv. or isopropyl monoxanthogen, is a golden yellow cryst. solid m 54–55°. Details are given of the production of isopropyl monoxanthogen.

Calcium humate. R. KEKÉTS. Hung. 100,679, Oct. 24, 1928. Materials in the state of primary carbonization (*e. g.*, peat, lignite or brown coal) are finely powdered and boiled under pressure with alkalies. The alkali humates are filtered and lime water is added to ppt. Ca humate.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. Fr. 37,109, June 17, 1929. Addn. to 630,511. Esters of *o*-aminocarboxylic acids of the anthraquinone series are prepd. by treating an anthraquinone-1,2-isoxazole with a compd. of the formula ROH in which R is an alkyl or aryl group such as alcs. or phenols in the presence of an agent of alk. action. Examples are given of the prepn. of the Et, Me and Ph esters of 1-aminoanthraquinone-2-carboxylic acid.

Azine derivatives. I. G. FARBENIND. A.-G. Brit. 339,283, Aug. 30, 1929. 1,2,5,6-Dibenzophenazine and its derivs. are made from 2-naphthylamine or its corresponding derivs. which contain a free 1-position by oxidation in an inert solvent of high b. p. with a metal oxide such as CuO or MnO_2. Several examples are given. Cf. *C. A.* **24**, 2242.

Benzanthrone derivatives. I. G. FARBENIND. A.-G. (Otto Braunsdorf, Eduard Holzapfel and Hans Lange, inventors). Ger. 518,410, Aug. 3, 1926. Addn. to 479,356 (*C. A.* **23**, 4830). The aminobenzanthronyl sulfides, etc., described in Ger. 479,356 are now prepd. by the action of NH_2OH in H_2SO_4 soln. on benzanthronyl sulfides, bisulfides, mercaptans or their derivs. The reaction is effected at about 125°, and a

catalyst may be present, *e. g.*, $FeSO_4$ or $CuSO_4$. Examples are given. Cf. *C. A.* **25**, 2301.

Cyclohexanol derivatives. SCHERING-KAHLBAUM (Walter Schoeller and Hans Jordan, inventors). Ger. 514,417, July 24, 1927. Addn. to 512,719 (*C. A.* **25**, 1260). Alkylisoalkylcyclohexanol and corresponding ketones are prepd. by subjecting a mixt. of the corresponding phenol and alkylated coumaran to the action of H, in the presence of catalyzers, until 6 or 8 H atoms are taken up, and sepg. the alkylated coumaran from the hydrogenated product. Thus, a mixt. of 4-methyl-6-isopropylenephenol and 2,4-dimethylcoumaran is treated with H at 150° in the presence of a Ni catalyzer. Pressure may be applied. The reaction is stopped when 8 atoms are taken up. A 60% yield of the hydrogenated product *p*-menthol and a 3–5% yield of *p*-menthone, can be obtained by careful fractional distn. Further examples are given.

Guanidine derivatives. REINHARD FREIHERR VON GODIN. Ger. 518,407, July 24, 1928. Salts of diguanidine derivs. of higher paraffin hydrocarbons are prepd. by the reaction of α,ω-dihalogenated higher paraffin hydrocarbons with guanidine in warm alc. soln. About 3 mols. of guanidine should be used for 1 mol. of halogenated hydrocarbon. Examples are given.

Substituted guanidines. HERBERT SCHOTTÉ (to Schering-Kahlbaum A.-G.). U. S. 1,795,738, March 10. In forming a compd. such as α-dimethyl-β-ethylguanidine, a dialkylcyanamide such as dimethylcyanamide is treated with a salt of an amine having at least one H atom attached to the N atom, such as ethylamine-HCl in the presence of the corresponding free amine.

Diacyl derivatives of *m*-xylene. I. G. FARBENIND. A.-G. (Otto Wulff, inventor). Ger. 515,540, Dec. 21, 1926. Aromatic or aliphatic acid chlorides are caused to react on monoacyl *m*-xylene derivs. or their $AlCl_3$ compds. at temps. above 50°. Excess of $AlCl_3$ and diluents may be present. In an example, acetyl-*m*-xylene is mixed slowly with $AlCl_3$ at 40°. $AcCl_3$ is dropped in at about 45°. The temp. is then raised to 85–90° for two hours, *i. e.*, until the HCl evolution ceases. The temp. is then raised to 95°. The reaction mass gives an 80% yield of diacetyl-*m*-xylene. Further examples are given.

Reduction products of *N*-acetylindoxyl. I. G. FARBENIND. A.-G. (Curt Schumann, Eduard Münch and Bruno Christ, inventors). Ger. 515,544, May 27, 1928. *N*-Acetylindoxyl, its homologs, anologs or derivs. are treated with H in the presence of hydrogenating catalyzers. Numerous examples are given. In one, *N*-acetyl-2,3-naphthindoxyl is treated with H at 100 atm. at 25° for 16 hrs., in an autoclave, in the presence of alc. and a Ni-kieselguhr catalyzer, to give *N*-acetyl-2,3-naphthodihydroindoxyl. Cf. *C. A.* **24**, 2142.

Solid compounds from hydrogen peroxide combinations. I. G. FARBENIND. A.-G. Brit. 339,332, Aug. 6, 1929. Gaseous mixts. contg. vapors of H_2O_2 are passed (suitably countercurrentwise) over substances which unite with it such as urea, methylolureas, acetamide, urethan, succinic amide, mannitol, erythritol, pinacol, $(CH_2)_6N_4$, or alkali metal sulfates, carbonates, borates, nitrates, phosphates or pyrophosphates (either with cooling, heating (to not above 80°) or at ordinary temp.). Stabilizers such as starch, dextrin, amines, EtOH, borates or acid or neutral pyrophosphates may be incorporated in small proportions with the solid substances, and the gaseous mixt. used may be obtained by the action of a silent elec. discharge or of ultra-violet rays on H contg. air or O.

Concentrating acids. SOC. ANON. DES DISTILLERIES DES DEUX-SÈVRES. Fr. 37,269, Mar. 19, 1929. Addn. to 651,528 (*C. A.* **23**, 3234). The processes of the prior patent and its addns. 34,574 (*C. A.* **24**, 1392) and 34,691 (*C. A.* **24**, 1392) are applied to the dehydration of org. acids in general and of the fatty series in particular. A solvent insol. or slightly sol. in water is used the b. p. of which is higher than that of the acid to be dehydrated, and which does not form an azeotropic mixt. with the anhyd. acid. A carrying substance giving with water an azeotropic mixt. boiling below the mixt. of water and solvent is also used. The method described in the addn. 35,750 (*C. A.* **24**, 4052) is varied by using an accessory liquid which forms with the acid to be dehydrated a binary mixt. of min. b. p. Cf. *C. A.* **25**, 970.

Acylated hydroxy fatty acids. ORANIENBURGER CHEMISCHE FABRIK A.-G. Ger. 515,679, Aug. 24, 1928. Hydroxy fatty acids or derivs. are treated with org. acids or their anhydrides or chlorides. A small quantity of $ClSO_3H$ is added during the acylation, and the product is neutralized after the reaction is over. Thus, ricinoleic acid is mixed with BzCl and a small quantity of $ClSO_3H$ added. After the reaction is over, the product is neutralized with NaOH. Further examples are given.

Mixtures of hydroxy fatty acids. CARL STIEPEL. Ger. 518,390, June 5, 1926.

Acid mixts. resembling the acids of castor oil are prepd. from unsatd. animal or vegetable fats or oils, or their free acids or their soaps, by partially satg. these by chlorination, and then replacing the Cl atoms by OH groups in known manner, by heating with NaOH soln. under pressure, etc. Examples are given.

Acid- and lime-resisting derivatives of unsaturated fatty acids. FERDINAND MÜNZ (to General Aniline Works). U. S. 1,796,801, March 17. Acids such as com. oleic acid or ricinoleic acid (heated to 150–60° until its acidity is reduced by about one-half, with formation of diricinic acid) are treated with fuming sulfuric acid contg. 66% of SO_3 (suitably in CCl_4) to obtain products which are not pptd. from soln. by hard water and are resistant to acids.

Pyrazoleanthrone-2-carboxylic acid. I. G. FARBENIND. A.-G. (Heinz Schever, inventor). Ger. 515,680, Apr. 6, 1928. N_2H_4 is caused to react on 1-haloanthraquinone-2-carboxylic acid. Examples are given. Cf. *C. A.* **25**, 969.

Phenylglycidic acid. ADOLF KAUFMANN. Ger. 515,034, Oct. 30, 1928. Addn. to 509,938 (*C. A.* **25**, 715). The method of 509,938 for forming the above acid by oxidation of cinnamic aldehyde is modified by using hypohalogenite soln. as the oxidizing agent. Examples are given.

1-Hydroxy-4-haloanthraquinone-2-sulfonic acids. I. G. FARBENIND. A.-G. (Ernst Honold, inventor). Ger. 518,214, Aug. 29, 1929. The diazo compds. from 1-amino-4-haloanthraquinone-2-sulfonic acids in an aq. medium are treated with Cu or a Cu compd. in the presence or absence of free acid. The amt. of Cu may be such that the product seps. as the insol. Cu salt. Examples are given.

Formic acid. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 339,045, Oct. 31, 1928. See Fr. 683,088 (*C. A.* **24**, 4522).

Acetic acid. HERMANN SUIDA. Austrian 120,859, Aug. 15, 1930. Concd. AcOH is recovered from dil. AcOH by extn. in the liquid phase with esters b. above 150° and derived from mono- or poly-basic cyclic carboxylic acids and mono- or poly-hydric alcs. Examples describing the use of dibutyl and diethyl phthalates are given. Cf. *C. A.* **24**, 3250.

Concentrating acetic acid. HERMANN SUIDA. U. S. 1,795,977, March 10. Dil. HOAc is subjected to cold extn. with a solvent such as anthracene oil and quinoline and the acid and extg. medium are sepd. by distn.

Concentrating acetic acid. HERMANN SUIDA. U. S. 1,796,059, March 10. A superheated aq.-HOAc vapor mixt. is brought into direct contact with a counter-flow of a liquid ester such as dihexyl phthalate to effect extn. of the HOAc from the mixt. and concd. HOAc is recovered from the soln. thus formed. App. is described.

Recovering acetic acid. HERMANN SUIDA. Austrian 121,251, Sept. 15, 1930. Dil. AcOH is extd. in the cold with a mixt. of a non-acetylatable base b. above 150° and pentachloroethane or a hydrocarbon b. above 150°. A suitable extg. mixt. is quinoline 1 and anthracene oil 1 part. Concd. AcOH is recovered by distg. the ext.

Acetic acid and other acids from nitriles. I. G. FARBENIND. A.-G. Brit. 339,235, Dec. 18, 1929. Nitrile vapors, either directly as produced by the method described in Brit. 332,258 (*C. A.* **25**, 115) or after previous condensation and revaporization, are saponified by continuously passing the nitrile vapor in contact with a current of inorg. acid such as a 50–90% H_2SO_4 or H_3PO_4. Various details and examples are given.

Anhydrides of aliphatic acids. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 338,507, Aug. 9, 1929. Anhydrides such as Ac_2O or butyric-acetic anhydride are obtained by heating "monobasic" aliphatic acids in admixt. with monoketones such as acetone or ketone-forming substances such as iso-Pr alc., secondary Bu alc., propylene oxide or MeOAc (suitably at about 600–700° and under ordinary, increased or reduced pressures). The materials may be passed through a heated tube of porcelain, quartz, yellow brass or other suitable material and catalysts may be used such as Cu, yellow brass or Al sulfate together with fillers such as porcelain, kieselguhr or pumice. Solid ketone-forming substances such as NaOAc or $Ca(OAc)_2$ may be used and caused to pass through the reaction tube by a device such as a screw conveyor.

Dehydrogenating isopropyl alcohol. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 339,491, Dec. 6, 1929. Isopropyl alc. vapor, with or without admixt. with other gases, is passed through a liquid medium such as molten Pb or salts or other non-reactive materials, heated to 300–700°, to produce acetone and H_2. Various details of app. and procedure are described.

Polymers of vinyl alcohol. I. G. FARBENIND. A.-G. (Fritz Klatte and Hermann Müller, inventors). Ger. 515,780, Nov. 29, 1929. Addn. to 514,598 (*C. A.* **25**, 2153). Polyvinyl mixed esters, which contain a halogenated org. acid and a non-halogenated

org. acid, are sapond. by NH_4OH. Thus, polyvinyl acetate chloroacetate is sapond. with NH_4OH to give a solid polyvinyl alc.

Acetaldehyde. Consortium für elektrochem. Ind. G. m. b. H. (Erich Baum and Martin Mugdan, inventors). Ger. 518,290, July 22, 1913. An excess of C_2H_2 is led through aq. H_2SO_4 of 6–35% concn. contg. a compd. of Hg, the acid being maintained at 60–80°. AcH is removed from the gases leaving the reaction vessel, and the excess of C_2H_2 is returned to the vessel.

Acetylene. Russell W. Millar (to The Shell Development Co.). Can. 309,544, Mar. 17, 1931. C_2H_2 is formed by the controlled combustion of a stream of O-contg. gas in an atm. of hydrocarbon gas.

Normal butyl oleate. Wm. J. Bannister (to Commercial Solvents Corp.). U. S. 1,796,231, March 10. Normal Bu oleate is made by reaction of butanol and oleic acid in the presence of H_3PO_4. It is a mobile yellow oily liquid, insol. in water, b_{10-18} 235–45°.

Acetals. Willy O. Herrmann and Hans Deutsch (to Consortium für Elektrochemische Industrie). U. S. 1,796,690, March 17. See Ger. 502,431 (*C. A.* **24**, 4793).

2,5,6-Trichloro-1,3-dimethylbenzene, etc. Georg Kalischer and Fritz Frister (to General Aniline Works). U. S. 1,796,108, March 10. 2,5,6-Trichloro-1, 3-dimethylbenzene, crystg. from glacial HOAc as white needles m. about 95–6°, b. 255–60°, is formed by the action of an inorg. acid on the corresponding 4-sulfonic acid (which in turn is obtained by reaction of NaOCl on 1,3-dimethylbenzene-4-sulfonic acid in aq. HCl soln.) and, in general chlorinated products are formed by treating 1,3-dimethylbenzene-4-sulfonic acid in a mineral acid soln. with a chlorinating agent. Depending on the amt. of Cl employed the mono-, di- or tri-chloro-1,3-dimethylbenzene-4-sulfonic acid is obtained. By hydrolysis effected in the usual manner, for instance, by heating with H_2SO_4 or H_3PO_4 or the like, the sulfonic acid group is split off from the mol. of the aforesaid compds. and the corresponding chlorinated benzene derivs. are obtained. For splitting off the sulfonic acid group from the trichloro-1,3-dimethylbenzenesulfonic acid an excess of Cl may be employed, whereby the sulfonic acid group is replaced by C and tetrachloro-1,3-dimethylbenzene is obtained. Details of procedure are also given for the production of 2-chloro-1,3-dimethylbenzene-4-sulfonic acid (the amide of which m. about 223°), 2-chloro-1,3-dimethylbenzene (b. about 185–7°), dichloro-1,3-dimethylbenzene-4-sulfonic acid (the amide of which m. about 330°), tetrachloro-1,3-dimethylbenzene (m. 218–20°) and derivs.

***m*-Nitroaniline.** G. A. Kirchov and I. T. Eskin. Russ. appl. 66,606, Mar. 18, 1930. *m*-$O_2NC_6H_4NH_2$ is prepd. by reducing an aq. suspension of *m*-$C_6H_4(NO_2)_2$ with Na_2S in the presence of NH_4Cl.

2,4-Dihydroxypyridine-3-carboxylic nitrile. Georg Schroeter. Ger. 515,991, Jan. 18, 1927. The above nitrile and its derivs. are prepd. from dihydroxyhalopyridinecarboxylic nitrile by (a) replacing the halogen by H or a substituted NH_2 group, or (b) treating with 1 mol. of an alkylating agent to form the *N*-alkylated pyridone compd., and substituting the halogen by H, OH, SH, NH_2 or substituted NH_2. Thus, 2,4-dihydroxy-6-chloropyridine-3-carboxylic nitrile is treated with 2 *N* H_2SO_4 and Zn dust to give the required nitrile. Or, the chloro deriv. is treated with NaOH and Me_2SO_4 to give 1-methyl-4-hydroxy-6-chloro-2-pyridone-3-carboxylic nitrile. The Cl is then substituted by H and treated with H_2SO_4 and Zn as before. Further examples are given.

Pure phenylazo-2,6-diaminopyridine hydrochloride. C. F. Boehringer & Soehne G. m. b. H. Ger. 515,781, Nov. 5, 1927. 2,6-Diaminopyridine is coupled with diazotized $PhNH_2$ in the presence of a sufficient amt. of dil. HCl to form the dihydrochloride at 12°. The dihydrochloride is then decomposed to the monohydrochloride by addn. of water. An example is given.

Hydroxythionaphthenes. Karl Schirmacher and Ernst Fischer (to General Aniline Works). U. S. 1,797,104, March 17. Hydroxythionaphthenes can be obtained with an excellent yield from compds. of the formula: $\begin{matrix}CX{:}CX.CX{:}C\ \text{alkyl}.\\ CH_2CO_2Z\end{matrix}$ $\begin{matrix}CY{:}CS-\\ \end{matrix}$ wherein X may be H, alkyl or halogen, Y may stand for CN, COOH, COO-metal and Z for H or a metal, by heating them with water to a temp. of 100–200°, preferably 180°, that is to say, by using such *o*-carboxythioglycolic acids, or salts thereof, or *o*-cyanothioglycolic acids as contain in *o*-position to the carboxyl or nitrile group a further substituent, particularly an alkyl residue. If there is no further substituent in *o*-position to the cyanogen group, no hydroxythionaphthene is formed. Examples with details of procedure are given for the production of 4-methyl-6-chlorohydroxythionaphthene and 4,7-dimethyl-6-chlorohydroxythionaphthene. Cf. *C. A.* **25**, 973.

Alkoxy-3-hydroxythionaphthenes. I. G. FARBENIND. A.-G. (Ernst Runne, Karl Moldaenke and Ernst Fischer, inventors). Ger. 515,541, Oct. 9, 1927. Alkoxyarylthioglycolic acid halides of the C_6H_6 or $C_{10}H_8$ series are treated with Al halides in the presence of solvents. Thus, 6-ethoxynaphthalene-2-thioglycolic acid (m. 122°) in C_6H_5Cl is converted to the chloride by addn. of PCl_5. $AlCl_3$ is added at 30–40° and the C_6H_5Cl steam-distd. off. An 80% yield of the corresponding ethoxybenzohydroxythionaphthene is obtained. Further examples are given. Cf. *C. A.* **24**, 379.

4-Alkylquinolines. SCHERING-KAHLBAUM A.-G. (Clemens Zöllner, inventor). Ger. 518,291, Jan. 15, 1927. $PhNH_2$ or its substitution products is caused to react with alkyl-β-haloethyl ketones in aq. acid or alk. soln. in the presence of an oxidizing agent. Thus, 4-methylquinoline is prepd. by heating on the water bath a mixt. of $PhNH_2$ with methyl-β-chloroethyl ketone, concd. HCl, and $PhNO_2$. Other examples are given also.

Anthraquinone and its derivatives. I. G. FARBENIND. A.-G. Fr. 37,337, June 26, 1929. Addn. to 673,825 (*C. A.* **24**, 2757). The transposition products, obtained by treating with alk. or acid agents or by heating the products resulting from the condensation of one mol. of benzoquinone with 2 mols., identical or different, of 1,3-butadiene hydrocarbons, are submitted to a regulated dehydrogenation which may be followed by a more vigorous dehydrogenation. The transposition and the regulated dehydrogenation may be carried out in one operation. 1,4,5,8-Tetrahydroanthrahydroquinone, 1,4,5,8-tetrahydroanthraquinone, their homologs and derivs. prepd. by this process are stated to be new. Cf. *C. A.* **25**, 965.

2-Aroylpyrazoleanthrones. I. G. FARBENIND. A.-G. (Heinz Scheyer, inventor). Ger. 518,120, Apr. 6, 1928. Pyrazoleanthrone-2-carboxylic acid or its *N*-alkyl or *N*-aralkyl derivs., or substitution products of any of these, are converted into the chlorides, and these are condensed with aromatic hydrocarbons or their substitution products in the presence of an acid condensing agent. Examples are given.

***N*-Substituted 3,6-diaminoxanthones.** IMPERIAL CHEMICAL INDUSTRIES. Ger. 515,524, Mar. 3, 1929. See Brit. 314,826 (*C. A.* **24**, 1521).

Phenols. E. PERILHOU. Brit. 338,638, Sept. 11, 1929. Phenols are sepd. from phenolic tar oils by treating the oils with aq. solns. of alkali carbonates under pressure and at temps. above 100°, with continuous escape of CO_2, isolation of the phenates thus formed and then decompn. of them with CO_2 liberated in the process, to regenerate the phenols. Various details of procedure and app. are described.

α-Naphthol. I. G. FARBENIND. A.-G. (Emil Laage, inventor). Ger. 518,409, Apr. 11, 1929. See Fr. 693,596 (*C. A.* **25**, 1539).

Coumarone. GES. FÜR TEERVERWERTUNG M. B. H. and OTTO KRUBER. Ger. 515,546, July 14, 1929. Heavy benzine contg. coumarone, is sulfonated and cooled in the presence of at least sufficient water-absorbing agent (*e. g.*, Ac_2O) to absorb the water formed during sulfonation. The resulting sulfonic acids are then split up by H, causing pure coumarone to sep. Examples are given.

Isatins. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORMALS ROESSLER. Ger. 515,542, May 13, 1927. Isatins are prepd. by converting *N*-substituted cyanoformarylides into the corresponding imide compds. at high temps. in the presence of condensing agents, and sapong. the product. Thus, diphenylcyanoformamide is shaken with concd. H_2SO_4. The product is cooled and treated with hot dil. NaOH, to give *N*-phenylisatin m. 140°. Other examples describe the prepn. of *N*-methylisatin, and *N*-ethylnaphthisatin.

Diphenolisatin. G. RICHTER, LTD. Hung. 101,105, Jan. 28, 1930. Isatin is condensed with phenol in dil. mineral acids.

1,2,4-Triazoles. GEORG SCHEUING and BRUNO WALACH (to C. H. Boehringer Sohn A.-G.). U. S. 1,796,403, March 17. Triazoles are in general obtained, *e. g.*, by treating oxime ester, *e. g.*, the benzenesulfonic acid esters of the oximes, with acylhydrazines under conditions under which the esters undergo Beckmann transformation to the imido ester of the corresponding secondary acid amide. Further, triazoles may also be obtained by subjecting oximes to the Beckmann transformation with the aid of acid halides, such as PCl_5, $POCl_3$ and the like and by causing acylhydrazines to react with the reaction product. The same imido compds. and therefore also the triazoles may be obtained from mono-substituted acid amides by acylating the same in their enolic form, *e. g.*, by treating the mono-substituted acid amides with acid halides, such as acid chlorides, and then causing an acylhydrazine to react with the reaction product. The 1,2,4-triazole is formed by the elimination of water from the resulting primary hydrazidine. Numerous examples with details of procedure are given and particular claim is made to *3-methyl-4-xylyl-5-isopropyl-1,2,4-triazole* as a new product, manuf. of which and of various similar compds. is described.

Thymol, etc. SCHERING-KAHLBAUM A.-G. (Hans Jordan, inventor). Ger. 518,209, Aug. 17, 1926. Thymol and its isomers and homologs are prepd. by hydrogenating the phenol-ketone condensation products obtainable as described in Brit. 273,684 (*C. A.* **22**, 1982), the process being continued until 4 atoms of H have been taken up. A phenolate or a compd. giving rise thereto may be present in the reaction mixt., as well as a catalyst promoting hydrogenation. Examples are given. Cf. *C. A.* **25**, 717.

Porphyrin. HANS FISCHER and JOSEF KLARER. Ger. 515,992, Oct. 9, 1926. Addn. to 509,939 (*C. A.* **25**, 716). The method of 509,939, for producing porphyrin by acting on halogenated dipyrrylmethenes with concd. H_2SO_4, is extended to include other acids. Examples mention HCOOH, succinic acid, AcOH and H_3PO_4. Cf. *C. A.* **25**, 716.

Skatole. GES. FÜR TEERVERWERTUNG M. B. H. and OTTO KRUBER. Ger. 515,543, Nov. 10, 1928. Skatole is obtained by treating the tar-oil fraction contg. indole homologs with Na or $NaNH_2$ at temps. above 165°, and sepg. the unchanged oil from the Na indole compds. The skatole is then sepd. from the oil by direct cooling. The mixt. of Na indole compds. may also be treated with CO_2 with exclusion of water, to cause the skatole to sep. Thus, crude indole oil is treated with Na at 190–5°. A stream of dry CO_2 is led in. An oil seps. above the lye. This is cooled to a low temp. to cause solid skatole to sep. Another example is given.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

A model for the segregation of enzyme from substrate (diastase-starch) in the cell. M. MÜHLBAUER. *Fermentforschung* **12**, 273–94(1931). —The sepn. existing between enzyme and substrate in the living cell and the more or less marked abolition of this sepn. under definite conditions is illustrated with pancreatic diastase and starch as a model. This spatial sepn. in the model is effected by superficially active substances which occur in the cell, such as Na oleate, lecithin, salts of bile acids and cholesterol. With Na oleate the sepn. of enzyme from substrate is brought about by its property of surrounding enzyme and substrate particles and thereby imparting to them a definite and uniform elec. charge. The enveloping film is thus a superficially active substance and the enclosed particles are mutually repelled by similar charges. The sepn. is reversible under biol. conditions. The reversal is best effected by changing the H-ion concn. In a mixt. of diastase and starch without soap, a change in p_H between 6.8 and 8.0 hardly exerts a measurable influence on the rate of digestion. If, however, the system contains soap, a slight change in p_H within these limits is of enormous influence. The time required for disappearance of the starch, as shown by neg. I reaction, may thus be several hrs. at the higher and only a few sec. at the lower p_H. The change in p_H toward the acid side merely removes the protecting soap film from the particles. The addn. of Ca salts has much the same effect, by pptg. the fatty acid as an insol. soap. Other superficially active substances can bring about a reversible sepn. of enzyme and substrate, *e. g.*, alcs. in isocapillary proportions. The hormones, adrenaline, thyroxine and insulin, and the ergot poison, ergotamine, were practically without influence. A. W. Dox

The problem of the specific action of tyrosinase. EMIL ABDERHALDEN AND WALTER SCHAIRER. *Fermentforschung* **12**, 329–32(1931).—Previous expts. with exts. of dried champignon [*Agaricus?*] showed that the tyrosinase present was very reactive toward *p* tyrosine, adrenaline and 3,4-dihydroxyphenylalanine, but inert toward *o*- and *m*-tyrosine. The expts. have now been repeated with practically the same results, except that a slight reddish coloration was noted at the surface of the *o*-tyrosine and 2-amino-tyrosine solns. The same effects were produced by a tyrosinase prepn. from dried potato peelings. On the other hand, exts. of *Russula delica* gave a pos. reaction with *m*-tyrosine, also with *o*- and *m*-cresol. The reaction was neg. with ephetonine, *d*- and *l*-ephedrine and thyroxine. The tyrosine dipeptides, glycyl-*l*-tyrosine, *d*- and *l*-alanyl-*l*-tyrosine, aminoisobutyryl-, *d*-valyl-, *d*- and *l*-norleucyl-, *d*- and *l*-leucyl-*l*-tyrosine and the corresponding haloacyl derivs. all reacted at p_H 6.5 with formation of the characteristic red color. 2,5-Iodo- and 2,5-dibromotyrosine reacted, also *l*-tryptophan, while *d*-alanyl-*l*-tryptophan remained colorless. Possibly the pos. result now obtained with *m* tyrosine is due to the presence of an addnl. enzyme. A. W. Dox

The active group of catalase. II. KARL ZEILE. *Z. physiol. Chem.* **195**, 39–48 (1931); cf. *C. A.* **25**, 119.—The close relationship between porphyrin-Fe content and catalase activity of horse liver ext. is further shown by the constancy of this ratio in prepns. purified by $Ca_3(PO_4)_2$ adsorption, dialysis, $Al(OH)_3$ adsorption, and $Ca_3(PO_4)_2$ adsorption after 76% inactivation. The same relationship is now shown to hold for catalase prepns. from plant sources. Expts. with the fungus, *Boletus scaber*, were unsatisfactory because of low enzyme activity and the presence of hemin in some other form which gave the hemochromogen reaction. A suitable source of plant catalase was found in the cotyledons of germinated pumpkin seeds. The max. activity develops between the 3rd and 6th days of germination. These cotyledons yield an ext. with $^1/_{15}$ the catalase activity of liver ext. The ratio of enzyme to porphyrin-Fe as detd. by the hemochromogen spectrum is approx. 8000, about 3 times as high as that of liver ext. The dissocn. const. of the HCN compd. of pumpkin catalase is about $^1/_3$ that of liver catalase. In both enzymes the active group is probably of similar constitution

A. W. Dox

Activators Z. H. v. EULER AND TORE PHILIPSON. *Z. physiol. Chem.* **195**, 81–100 (1931).—Caffeine, theobromine, xanthine, tryptophan, adenosine, thymidine and hemin, in concns. of 1–5 mg. per cc., have no influence on the rate of fermentation, even in the presence of an activator Z prepn. Plant material from various sources was examd. for the presence of activator Z but the evidence was very slight except in malt germs where the ext. showed practically the same activity as boiled yeast ext. Z consists of 2 factors which are differentiated by their temp. stability and, like vitamin B, are more sensitive to alkali than to acid. Various pptn. and adsorption reactions were applied with a view to purifying the Z factors. A concd. yeast dialyzate was freed from certain impurities by treatment with $Pb(OAc)_2$ and $Hg(OAc)_2$. The filtrate was then used for adsorption expts. Treatment with $AgNO_3 + Ba(OH)_2$ removes some of the activity. Picric acid does not ppt. the activator, since the loss of activity is not restored by recombining the ppt. and filtrate. Addn. of MeAc to 95% gives a ppt. which contains the full activity, and about 40% of the inert material is left in the filtrate. $Fe(OH)_3$ gives a ppt. from which the Z activator can be recovered by elution with 1% KH_2PO_4, but without the preliminary Pb-Hg treatment the adsorption of activator does not occur. The Fe filtrate does not give up its active substance to charcoal, regardless of the p_H of the medium. A good adsorbent is $Ba_3(PO_4)_2$ when this is prepd. in the presence of the activator; otherwise no adsorption is effected. Recovery of the activator from this ppt. cannot be accomplished by elution but requires a decompn. of the phosphate by H_2SO_4. $AlPO_4$ has the advantage of insoly. in AcOH and the activator which it adsorbs can be released by AcOH extn. and thus freed from phosphate. $Al(OH)_3$ gives the same adsorption as $Fe(OH)_3$. The activation of yeast by activator prepns. reaches a max. beyond which further addn. is ineffectual. Bottom yeast is activated to the same extent by the original dialyzate as by the Fe filtrate; hence it is influenced only by that part of the Z activator which is not adsorbed by $Fe(OH)_3$.

A. W. Dox

The nature of the proteases. VIII. Refractometric studies on the activity of various pepsin preparations. I. A. SMORODINTZEV, A. N. ADOVA AND S. S. DROSDOV. *Z. physiol. Chem.* **195**, 113–20(1931); cf. *C. A.* **25**, 1268.—The sol. products resulting from digestion of an insol. protein, such as fibrin, increase the n of the medium. By detg. the n of the soln. after enzyme and substrate have reacted under standard conditions it is possible to compare the activity of various pepsin prepns. Control expts. with enzyme alone show that the more active prepns. have higher n values.

A. W. Dox

Studies on the intermediary metabolism of tryptophan. I. Kynurenine, an intermediary metabolic product of tryptophan. Y. KOTAKE AND J. IWAO. *Z. physiol. Chem.* **195**, 139–47(1931).—When tryptophan is injected subcutaneously into rabbits whose metabolism has been lowered by a regime of polished rice, a product intermediate between tryptophan and kynurenic acid is excreted in the urine. The name *kynurenine* is proposed for this substance. If the kynurenine is present in considerable amt. it can be crystd. out directly as sulfate by addn. of H_2SO_4 and a little Et_2O, but ordinarily its isolation requires a pptn. by phosphotungstic acid or $HgSO_4$ and decompn. of the ppt. by $Ba(OH)_2$ or H_2S. Kynurenine is $o\text{-}H_2NC_6H_4C(CO_2H):CHCH(NH_2)CO_2H$. It m. 190° (decompn.) with previous sintering and darkening, and has $[\alpha]_D^{17} -28.5°$. It forms a *sulfate* which begins to darken at 165° and becomes black at 180°, and has $[\alpha]_D^{18}$ 10.7°. Esterification by satg. the EtOH soln. with HCl gives a *diethyl ester di-HCl salt*. The α-NH_2 is shown by the ninhydrin reaction, and the double bond in

the side chain by the addn. of 2 Br to form a *dibromide*, m. 206–7° (decompn.), which is the lactone of the aromatic NH_2 and the γ-CO_2H, and is thus an indole deriv. Excretion of kynurenine is accompanied by a decrease in kynurenic acid excretion. On the other hand, when kynurenine is fed to rabbits 20–40% may be recovered as kynurenic acid. **II. The cleavage of kynurenine by means of barium hydroxide.** Y. KOTAKE AND M. KIYOKAWA. *Ibid* 147–52.—Kynurenine is very stable to acids and withstands 10 hrs.' boiling with 25% H_2SO_4. It is very unstable to alkalies, splitting off NH_3 and CO_2. After boiling with 1% $Ba(OH)_2$ the products isolated were *o-aminoacetophenone* in 70–81% yield (identified as the HCl salt, m. 264–5°, the Ac deriv. m. 75–6°, the mono-Br deriv. of the latter, m. 157–8°), and kynurenic acid. The reaction is best explained by the intermediate formation of *o-aminobenzoylpyruvic acid*, which on the one hand would yield *o*-$H_2NC_6H_4Ac$ and $C_2H_2O_4$ by hydrolysis, and on the other hand kynurenic acid by enolization and ring closure to the quinoline structure. These products of hydrolysis furnish further proof of the structure of kynurenine (see above). **III. The cleavage of kynurenine by means of sodium bicarbonate solution.** Y. KOTAKE AND G. SHICHIRI. *Ibid* 152–8.—When refluxed with 2% $NaHCO_3$ kynurenine splits of NH_3 and the soln. becomes canary yellow, then orange yellow and soon shows fluorescence. Some *o*-$H_2NC_6H_4Ac$ is formed, but much less than in the cleavage by $Ba(OH)_2$. After removal of this by Et_2O extn., the orange-yellow product may be obtained from the mother liquor by acidifying and again extg. with Et_2O. The substance crystallizes on evapn. of the Et_2O, but is unstable to air, light and heat. Its m. p. varies considerably with different prepns.; hence the substance is probably not pure. Further treatment with $NaHCO_3$ or $Ba(OH)_2$ yields $H_2NC_6H_4Ac$ but no NH_3. When treated with warm water part of the substance dissolves and part forms an oil. A soln. of the latter in Et_2O shows an intense blue fluorescence and yields yellow crystals of *kynurenine yellow*, m. 182°, an unstable substance closely related to kynurenic acid. The orange-yellow product obtained from kynurenine by $NaHCO_3$ cleavage probably consists mainly of *o-aminobenzoylpyruvic acid*, a part of which appears to be present in a condensation form. Kynurenine gives a blue color reaction when its aq. soln. is treated with $PhNHNH_2.HCl$ and $NaHCO_3$, the mixt. heated to boiling, then cooled and treated with concd. H_2SO_4. **IV. The mechanism of kynurenic acid formation in the organism.** Y. KOTAKE. *Ibid* 158–66.—The discovery of kynurenine as an intermediate in the metabolism of tryptophan to kynurenic acid, and the elaboration of its structural formula, furnishes an important link in the chain of reactions involved in the breakdown of tryptophan. The successive reactions are now believed to occur as follows: (1) tryptophan is oxidized to its Py-α-hydroxy deriv.; (2) the pyrrole ring is opened by hydrolysis to γ-*o*-aminophenylglutaric acid; (3) removal of 2H from the glutamic acid grouping yields kynurenine; (4) CO_2 and NH_3 are removed by oxidation, yielding *o*-aminobenzoylpyruvic acid; (5) the tautomeric form of the latter closes to a quinoline ring with formation of kynurenic acid. **V. The formation of kynurenic acid from kynurenine by microörganisms.** G. SCHICHIRI AND M. KIYOKAWA. *Ibid* 166–71.—Synthetic culture media to which kynurenine had been added as the source of N were inoculated with *Oidium lactis* and *Willia anomala* and incubated for 17 and 33–89 days, resp. Both organisms converted part of the kynurenine into kynurenic acid, which was isolated and identified by m. p. and by analysis of the Ba salt. From the mold culture a small quantity of a substance m. 122° was obtained by Et_2O extn.; it was probably anthranilic acid. The yeast culture contained a colored substance possessing the general properties of urochromogen. A medium contg. 2,3 quinolinedicarboxylic acid gave a good growth of mold but no kynurenic acid. From kynurenine the max. yield of kynurenic acid was 60%. The cleavage of kynurenine by yeast is essentially the same as that by the animal organism, and supports the view that the formation of kynurenic acid and urochrome from tryptophan in the animal organism occurs via kynurenine. **VI. The excretion of kynurenic acid in the bile and its stability in the organism.** Y. KOTAKE AND K. ICHIHARA. *Ibid* 171–9.—The path of excretion of the kynurenic acid formed in the organism from tryptophan varies with different animals. With dogs the excretion is often greater in the bile than in the urine, while with rabbits the excretion is entirely in the urine. This explains the variable results reported on dogs where only the urine was examd. Kynurenic acid, after subcutaneous injection as the Na salt, is excreted in both bile and urine by rabbits as well as dogs. It is not utilized by the organism, but is eliminated quantitatively, although only slowly after large doses. Kynurenic acid is not an intermediary product but an end product of tryptophan metabolism. **VII. The site of formation of kynurenic acid in the organism.** K. ICHIHARA, S. OTANI AND J. TSUJIMOTO (WITH COLLABORATION OF Y. OKAGAWA AND T. KIYOMATSU). *Ibid*

179-84.—Tryptophan was administered subcutaneously to dogs that had been hepatectomized after connecting the portal vein to the vena cava by means of a canula. The animals lived 9.5 and 12.5 hrs., resp., at the end of which time the blood and urine were examd. for kynurenic acid. The results were neg. A perfusion expt. in which defibrinated blood contg. kynurenine was passed 18 times through the isolated liver gave an 18% yield of kynurenic acid. In a control expt. without kynurenine no kynurenic acid was obtained. It is evident that conversion of kynurenine into kynurenic acid occurs in the liver. The excretion of kynurenic acid is increased by extirpation of the spleen. **VIII. The question of the origin of urochromé.** Y. KOTAKE AND H. SAKATA (WITH COLLABORATION OF Y. SHIRABE AND S. OTANI). *Ibid* 184-91.—After ingestion of 3 g. of tryptophan the urochrome content of the alloxyproteic acid fraction of the urine, as detd. colorimetrically, nearly doubled. The Ba and Ca salts prepd. from this fraction were easily sol. in H_2O and gave the Pauly diazo and the PbS reactions, but neither the biuret nor the Ehrlich diazo reaction. The N content of the urochrome fraction varied with the intensity of the color. When kynurenine instead of tryptophan was administered the Ehrlich reaction became pos. The urine then had a greenish color which became yellow on standing in the air. The urochromogen or urochrome is formed from tryptophan by way of kynurenine. Oral administration of tryptophan to a patient with pulmonary phthisis gave a marked increase in diazo and urochrome values of the urine. **IX. The effect of tryptophan on experimental anemia and its relation to the spleen.** Y. OKAGAWA and M. TATSUI. *Ibid* 192-202.—The recovery from exptl. anemia produced in dogs by injection of $PhNHNH_2 \cdot HCl$ is somewhat more rapid, as detd. by erythrocyte count and hemoglobin content of the blood, if the animals are given injections of tryptophan every 2 days. If the anemia is produced 25-45 days after removal of the spleen, recovery is less rapid and is not accelerated by the tryptophan treatment. One year after splenectomy the tryptophan treatment is somewhat more effective in curing exptl. anemia. The spleen appears to play some role in the utilization of tryptophan for purposes of blood building. The liver contains somewhat more tryptophan than the kidney. The amts. present undergo practically no change within 40 days after extirpation of the spleen, but after a longer period the tryptophan content of the liver increases. This compensation of spleen function also supports the view that tryptophan can serve as building material for hemoglobin formation. **X. *dl*-Indolelactic acid and its use in nutrition.** K. ICHIHARA AND N. IWAKURA. *Ibid* 202-7.—The indolelactic acid used by Jackson (*C. A.* **21**, 3079) with neg. results as a substitute for tryptophan in feeding expts. was not the *dl*-form as J. supposed but the *l* form as indicated by m. p. The *dl*-acid prepd. by autoclaving the *l*-acid with $Ba(OH)_2$ until optically inactive, and tested by mixed m. p. with synthetic *dl*-acid obtained by reduction of indolepyruvic acid, gives positive results with rabbits. The acid recovered from the urine was mainly the *l*-form, showing that the *d*-acid was actually utilized. Feeding expts. with rats showed that a loss in wt. occurred when the animals received a tryptophan-free ration consisting of hydrolyzed casein, cystine, tyrosine, starch, sugar, salt and agar. When this ration was supplemented by *dl*-indolelactic acid the animals more than made up the loss. Indolepyruvic acid and *l*-indolelactic acid were ineffectual as substitutes for tryptophan. **XI. The effect of methyltryptophan on artificial anemia and nutrition.** Z. MATSUOKA AND T. NAKAO. *Ibid* 208-14.—As measured by increase in erythrocyte count and hemoglobin content and decrease in reticulocytes, the recovery of guinea pigs from exptl. anemia is more rapid with α-methyltryptophan than with tryptophan administered subcutaneously. On the other hand, the feeding of α-methyltryptophan to rats does not compensate a dietary deficiency in tryptophan. The action of methyltryptophan, and probably that of tryptophan, in curing exptl. anemia is independent of their nutritional value.

A. W. DOX

The chemical nature of urease. ERNST WALDSCHMIDT-LEITZ AND FELIX STEIGERWALDT. *Z. physiol. Chem.* **195**, 260-6(1931).—The protein character of cryst. urease brings up the question whether the enzyme is actually a protein or whether the protein is merely a carrier which stabilizes the enzyme. The effect of activators such as amino acids and HCN is to overcome the inhibitory effect of accessory substances, since the activation is observed only with crude enzyme and not with purified or cryst. prepns. The protein is not an essential component of urease, as shown by the fact that proteolysis by pancreatic ext., trypsin or papain-HCN to the point where sulfosalicylic acid no longer gives a ppt. does not diminish the activity of the enzyme. Hydrolytic products resulting from the breakdown of this protein function equally well as carriers of the urease activity. The protein may even be only an accessory concomitant of the pure enzyme.

A. W. DOX

The intermediary metabolism of histidine. III. S. Edlbacher and J. Kraus. *Z. physiol. Chem.* **195**, 267-72(1931); cf. *C. A.* **25**, 118.—In the enzymic cleavage of histidine, previously reported, the products isolated were glutamic acid, HCO_2H and $2NH_3$. The method of isolation, however, involved the use of NaOH and HCl, and the possibility remains that the end products were thus formed from an unknown intermediate. Kauffmaan and Mislowitzer (*C. A.* **25**, 307) have since shown that the use of Na_2CO_3 instead of NaOH yields only $1NH_3$. This observation is now confirmed by E. and K. The possible intermediates glutamine and $HCONH_2$ show the same difference in behavior toward Na_2CO_3 and NaOH. Both differ, however, from the histidine intermediate in that the former is hydrolyzed by dil. HCl while the latter is not. In the progress of the enzymic cleavage of histidine the ratio of NH_3 liberated by Na_2CO_3 to that liberated by NaOH decreases from 0.83 after 2 hrs. to 0.58 after 24 hrs., where it then remains const. The first attack of the enzyme breaks open the imidazole ring and liberates $1NH_3$. The product is probably an amide which is hydrolyzed by NaOH but is resistant to HCl. Whether a further breakdown is due to enzymic action or to a spontaneous decompn. has not as yet been detd. A. W. Dox

An easily cleavable phosphoric acid compound in yeast. Hans v. Euler and Ragnar Nilsson. *Z. physiol. Chem.* **195**, 273-6(1931).—Ext. of dried yeast, after removal of protein by CCl_3CO_2H, contains a substance from which H_3PO_4 is not pptd. by magnesia mixt. and NH_4OH but which gradually forms a ppt. with Embden's reagent. The H_3PO_4 is thus easily split off. The amt. of this complex rapidly diminishes during the first few hrs., but less rapidly in the presence of added Na hexosediphosphate. In the presence of H_3PO_4 it increases while the H_3PO_4 disappears within 2 hrs., then the amt. rapidly decreases. Addn. of creatine retards this synthesis. A. W. Dox

Pepsin. (**Preliminary paper.**) Heinz Holter *Z. physiol. Chem.* **196**, 1-9 (1931).—The early stages of peptic digestion were studied by measuring the changes in viscosity of a 3% casein soln. at p_H 2.3 and 30°. Dil. pepsin solns. were used in order to prolong the initial stage and make possible a greater no. of observations. The viscosity, as measured by timing the flow through a viscometer, decreases in the very first phase of the digestion and soon reaches a min., after which it rapidly increases and attains a sharp max., which is a multiple of the original value. This stage marks the coagulation of the entire casein soln. As the digestion proceeds there occurs a sepn. of phosphopeptone, and with increasing d. of the floccules the viscosity again decreases. The peptic cleavage was followed by means of the Linderström-Lang acid titration in acetone. The initial digestion stage in which viscosity decreases was studied in particular. Viscosity change is not a simple function of cleavage but varies with the nature of the peptide linkages broken. The ratio between cleavage and viscosity is different for different pepsin prepns. but const. for one and the same prepn. The curve can serve for characterization of a pepsin digestion just as the location of p_H optimum toward definite substrates distinguishes different proteolytic enzymes. Studies were made of different pepsin prepns., including Northrop's crystd. pepsin, and fractions obtained by adsorption on $Al(OH)_3$. The sep. fractions give different curves, but when they are recombined the original curve is again obtained. Even the crystd. pepsin is amenable to fractionation. Peptic action is therefore not a simple phenomenon, and the variations noted must be due to differences in the enzyme itself. A. W. Dox

The physiological actions of cozymase. Sven Gard. *Z. physiol. Chem.* **196**, 65-70(1931).—Injection of cozymase into the jugular vein of rabbits under urethan narcosis causes a lowering of blood pressure. This effect is independent of the specific action of cozymase, since inactivation by heating does not diminish it. Pure adenylic acid of yeast is somewhat more active in this respect, possibly because of the fact that cozymase is not an entirely pure adenylic acid. Adenylthiomethylpentose has about the same effect. Introduction of the thiomethyl group into the adenosine mol. apparently does not diminish this special action. In the surviving rabbit heart, on the other hand, cozymase injection is followed by a considerable increase in activity, perhaps on account of dilation of the coronary vessels. Here also there is no difference in effect between active and inactive cozymase. The action of cozymase in lowering the blood pressure is a non-specific effect of adenylic acid or homologous adenosine derivs., which corresponds to that observed by Zipf with muscle adenylic acid. A. W. Dox

Cytochrome. R. Bierich and A. Rosenbohm. *Z. physiol. Chem.* **196**, 87-8 (1931).—The discrepancy pointed out by Shibata and Tamiya (*C. A.* **24**, 3533) between his results and those of B. and R. (*C. A.* **24**, 133) with regard to the influence of KCN in preventing the disappearance of the cytochrome band by oxidation is due to the fact that the cytochrome in the first instance was of vegetable origin (yeast) while in

the 2nd it was of animal origin (rat testes). In animal tissues the B component is oxidized in the presence of KCN while the C and A components remain reduced.
A. W. Dox

The absorption of ultra-violet light by amino acids (fragments of proteins). H. Guthmann, K. Schwerin and F. Stähler. *Strahlentherapie* **39**, 401–41(1931).—In synthetic mixts. of the amino acids corresponding in compn. to albumin, globulin and fibrin, 2 absorption maxima are present, at 300$\mu\mu$ and 250$\mu\mu$, which are the specific bands for the action of the ultra-violet rays on the skin. Tyrosine, phenylalanine and glutamic acid are the substances which absorb the ultra-violet rays very powerfully. In substances of the propionic acid series (propionic acid, alanine, phenylalanine, tyrosine, histidine and tryptophan) the influence of various groups on the absorption power is entirely independent of the mol. wt., but depends on the stereochem. structure of the mol. The most powerful in this respect is the aldehyde group; the activity decreases in the order NH_2, CO_2H, OH.
F. R. Greenbaum

The biologic action of Röntgen rays. Action of Röntgen rays on the potassium and calcium in the blood serum of man. G. Schaal, M. A. Gruschetzkaya and E. J. Zwilichwoskay. *Strahlentherapie* **40**, 111–23(1931).—Röntgen rays caused a change in the quotient K/Ca in the human blood serum. The direction of this change seems to depend upon the time interval between irradiation and blood examn. After the first day of the radiation, the K seems to be increased but later on the Ca seems to be increased. This may account for the following phenomena: fluctuation of a no. of leucocytes, analgesic action, early reactions and poisoning due to Röntgen treatment.
F. R. Greenbaum

Biologic investigations on the transparency of gypsum and mica to ultra-violet. Tomoshige Takagi. *Strahlentherapie* **40**, 189–92(1931).—Light from a Hg-arc lamp which has passed through natural plates of gypsum is very active on blood agar plates as well as on the human skin; light filtered through mica was without action.
F. R. Greenbaum

Effect of hydrogen-ion concentration upon the precipitation of certain basic substances by phosphotungstic acid. Rudolf A. Peters. *Biochem. J* **24**, 1852–5 (1930).—With most bases the pptn. appears upon passing from a more alk. to a less alk. soln., with guanidine compds., this is reversed.
Benjamin Harrow

Inhibition of esterases by excess substrate. David R P. Murray. *Biochem J.* **24**, 1890–6(1930).—Haldane's suggestion ("Enzymes," p. 84(1930); cf. *C. A.* **25**, 720) that the inhibition of certain enzymes by excess of substrate is due to the formation of a non-hydrolyzable complex of the enzyme with 2 mols. of the substrate, has been tested for the esterase of sheep liver and found to explain the facts.
Benjamin Harrow

Crystalline urease: a review. Henry Tauber. *J. Am. Inst. Homeopathy* 24, 366–8(1931).—The literature on urease is reviewed. A bibliography is given.
Joseph S. Hepburn

Prothrombase: its preparation and properties. John Mellanby. *Proc. Roy Soc.* (London) **B107**, 271–85(1930).—Prothrombase is prepd. from oxalated mammalian serum by: (1) pptn. of its globulin complex at p_H 5.3 after diln. with 10 vols. of H_2O, (2) extn. from this complex with a dil. soln. of $Ca(HCO_3)_2$ and (3) pptn. from the resulting soln. by addn. of acid to p_H 5.3. Approx. 40 mg. prothrombase results from 100 cc. plasma; as a rule, 1 mg. of the prepn., after its conversion into thrombase coagulates 100 cc. plasma in 20 sec. Prothrombase is a white amorphous powder giving the characteristic reactions of acid metaprotein; it is insol. in H_2O, readily sol in dil. alkali and not dialyzable through a collodion membrane. Heating at a temp of 100° for 5 min. does not destroy prothrombase, but diminishes the rate at which it may be activated. Activation is produced by addn. of thrombokinase, is initially slow and proceeds with a rapidly increasing velocity, is influenced by the reaction of the medium and the temp., is accelerated greatly by the presence of small quantities of Ca or Sr, and slightly by Ba or Mg.
Joseph S. Hepburn

Porphyrin of component *c* of cytochrome and its relationship to other porphyrins. R. Hill and D. Keilin. *Proc. Roy. Soc.* (London) **B107**, 286–92(1930).—Unmodified cytochrome *c* of bakers' yeast yields 2 different porphyrins. The *one* porphyrin, obtained by the action of HBr and AcOH, is indistinguishable from hematoporphyrin having the following properties of the latter: (1) soly. in Et_2O and AcOH, (2) absorption spectra in Et_2O and in HCl, (3) combination with Fe, various compds. of N, and globin to form hemochromogens or hemoglobins, (4) conversion into protoporphyrin by (*a*) heating *in vacuo*, or (*b*) heating the corresponding hematohematin *in vacuo*, or (*c*) heating the hematohematin in AcOH in a sealed tube. The *other* porphyrin results from the action of HCl in the presence of a reducing agent such as SO_2; it is insol in

Et_2O and AcOH and in $CHCl_3$. Its absorption spectrum may be detd. in either acid or pyridine; its absorption bands lie between those of hematoporphyrin and protoporphyrin, but nearer to those of the former. Recombined with Fe and a N compd. *e. g.*, pyridine, it forms a hemochromogen indistinguishable from that of component *c* dissolved in pyridine. It gradually changes into hematoporphyrin on prolonged standing in HCl in the presence of SO_2. JOSEPH S. HEPBURN

Differential action of x-rays on tissue growth and vitality. II. The biological reaction to x-radiation in relation to a phenomenon called antagonism. WARNFORD MOPPETT. *Proc. Roy. Soc.* (London) B107, 293–301(1930); cf. *C. A.* **24**, 2152; **III. The biological reaction to x-radiation in relation to the area of tissue irradiated.** *Ibid* 302–7. **IV. The biological reaction to x-radiation in relation to time.** *Ibid* 308–12. Some attention is paid to ionization or similar changes in the atom as the result of irradiation. JOSEPH S. HEPBURN

Recent advances in science: biochemistry. P. EGGLETON. *Science Progress* **25**, 393–8(1931).—A review is given of recent work on enzymes, p_H and r_H, and hexose phosphates. JOSEPH S. HEPBURN

Nitrogen peroxide from the mechanical rectifiers of a deep x-ray therapy plant. ROLLO K. NEWMAN. *Med. J. Australia*, May, 1930; Sidney Univ. Reprints Ser. 3, 1, Nos. 45–61, 4 pp.—The air around the mech. rectifiers of an x-ray therapy plant was found to contain sufficient NO_2 to be a source of danger to operators and patients. Efficient ventilation is considered imperative. C. E. P. JEFFREYS

Studies on the biochemistry of sulfur. VI. Cystine content of conphaseolin and phaseolin, the α- and β-globulins of the navy bean (Phaseolus vulgaris). M. X. SULLIVAN AND D. BREESE JONES. *U. S. Pub. Health Repts.*, Suppl. No. 82, 9 pp. (1930); *C. A.* **24**, 4796.—With the highly sp. Sullivan method, it was found that conphaseolin, the α-globulin of the navy bean, contains over 1% cystine, while phaseolin, the β-globulin, if free from the α-globulin, contains little, if any, cystine—a chem. finding in keeping with the results of feeding expts. The β-globulins of the mung bean, the adsuki bean and, to a degree, the lima bean are also deficient in cystine. The α-globulins, on the contrary, are relatively rich in cystine. Since the protein of these beans is mainly the β-globulin, the beans as a whole would tend to be deficient in cystine. Accordingly, in general diets, these beans should be used with foodstuffs rich in cystine, such as meat, fish and eggs. There are 19 references to the literature. **VII. Cystine content of purified proteins.** M. X. SULLIVAN AND W. C. HESS. *Ibid* No. 86, 11 pp. (1930).—The cystine content of 23 purified proteins was detd. by estg. cystine in hydrolyzates. The methods employed were the Sullivan, the Okuda, the Folin-Looney and, with 14 proteins, the Folin-Marenzi (cf. *C. A.* **23**, 4492). With material in which cystine is the predominant S compd., such as wool and serum albumin, the Folin methods and the Sullivan and Okuda methods gave concordant results. In many cases the Folin-Looney and the Folin-Marenzi methods gave higher values. For all the proteins listed, the Sullivan colorimetric method and the Okuda iodometric method gave results of the same order of magnitude, with the Okuda values slightly higher. The Sullivan and Okuda method gave results with the β-globulins of various beans in agreement with feeding expts. which indicate that these globulins are deficient in cystine; the Folin-Looney method gave cystine findings not in such agreement. As judged from the exptl. data, comparison with feeding expts., etc., it would seem that the higher degree of probability of the correctness of the cystine findings is with the Sullivan method, with the Okuda method closely following. It has been found that a mixt. of NH_2 acids such as exist in casein without cystine or other S compds. gives, on heating with acid, a mixt. which reacts strongly pos. in the Folin-Marenzi test for cystine though neg. with the Sullivan and the Okuda methods. There are 25 references to the literature. J. A. KENNEDY

Amylosynthease. SUKEHARU NISHIMURA. *J. Agr. Chem. Soc. Japan* **6**, 160–7, 485 6, 987–90(1930); **7**, 29–35(1931).—The aq. ext. of yeasts contains enzymes which liquefy starch, coagulate the starchy soln. of glutinous rice and polymerize dextrins. The I reaction of amylase degradation products is lessened by the yeast ext. When the yeast ext. was used with amylase the amylolytic action was accelerated markedly. The optimum p_H and temp. for the amylosynthease of the yeast ext. were, resp., 6.2 and 20°. Warming at 55–60° for 10 min. destroys the activity. The synthetic action was proved with a clear soln. of sol. glutinous rice starch. The I color reaction changed from red to violet after 3 days and the ppt. appeared after 4–5 days. The ppt. is difficultly sol. in water and gives a blue-violet I reaction. Amylase causes the ppt. to lose this reaction. Thus polymerization was proved. The yeast ext. was purified with colloidal Fe oxide at p_H 6.5. The purified enzyme was added to achro-

dextrin, in which the I reaction was yellow, and kept for 10 days at 20° and p_H 6.2. The soln. gives a violet-blue color reaction for I-IK. From the soln. the synthesized dextrin was pptd. It was proved by the reactions, the soly., the viscosity and mol wt. to be a polymerized dextrin. The existence of amylocoagulase in the malt ext. could not be verified. But coagulation of starch by the yeast ext. was found at any concn. Amylocoagulase and amylosynthease exist in the yeast ext. Sol. starch was hydrolyzed as much as possible by malt amylase and then the yeast ext. was added. The I reaction became violet after 18 days. The synthesized dextrin was pptd. by alc. The hydrolysis of the synthesized dextrin by amylase was like that of starch.
Y. KIHARA

Proteins of wool. II. MICHIO SAITO. *J. Agr. Chem. Soc. Japan* **6**, 1109-24 (1930).—The wool was treated with 1% HCl under 5 atm. pressure for 5 hrs. Ninety % of the solid matter was dissolved. By fractional pptn. 6 albumoses and a peptone were obtained. These are compared.
Y. KIHARA

Glucuronic acid fermentation. TEIZO TAKAHASHI AND TOSHINOBU ASAI. *J. Agr. Chem. Soc. Japan* **7**, 1-5(1931).—By the fermentative action of *Bact. industrium var.* Hoshigaki on a medium consisting of 1 l. yeast ext., 100 g. glucose and 25 g. CaCO for 30 days, 35 g. Ca hydroxygluconate was obtained. From the filtrate 20 g. Ca gluconate was obtained. By the addn. of MeOH to the filtrate of Ca gluconate, 20 g Ca glucuronate was pptd. Ca glucuronate was proved by the color reactions, sp rotation of the free acid ($[\alpha]_D^{23}$ = −18.5°) and Ca salt ($[\alpha]_D^{23}$ = −24.0°), phenyl osazone, m. 131-2°, *p*-nitrophenylhydrazone, m. 209-10°, Ba salt of *p*-bromophenyl osazone, m. 204-7°, and brucine salt, m. 178-9°. From the fermentation products of *Bact. industrium var.* Hoshigaki on a medium of yeast ext. and Ca gluconate, 5 g. Ca glucuronate was obtained. The bacteria produce glucuronic acid and hydroxyglucomc acid not only from glucose, but also from gluconic acid.
Y. KIHARA

Amylase from wheat. DATTATREYA V. KARMARKAR AND VINAYAK N. PATWARDHAN. *J. Indian Inst. Sci.* **13A**, 159-64(1930).—The amylase from wheat is more active than that from barley. Its optimum temp. is 49-58°; p_H 4.6. Heating the dry enzyme at 160° for 1 hr. destroys its activity, which is not regenerated by adding salts or amino acids. Inactivation results on prolonged dialysis through collodion bags or in the presence of pepsin. Neutral salts and amino acids are without influence.
MARY E. LEAR

Isolation of protein crystals possessing tryptic activity. JOHN H. NORTHROP AND M. KUNITZ. *Science* **73**, 262-3(1931).—A cryst. protein has been isolated from a com. prepn. of "trypsin" which digests casein and gelatin in neutral solns. The digestive power of the crystals is about 10 times that of the most active com. prepns. The activity remains const. through 3 successive crystns. The substance is unstable and may become less active during its prepn. unless proper care is exercised. The process of prepn. of the substance is briefly outlined.
B. S. LEVINE

The action of blood on acetylcholine. K. MATTHES. *J. Physiol.* **70**, 338-48 (1930).—The destruction of acetylcholine by blood is due to the action of an esterase, which is specifically inhibited by eserine and also by fluorides.
J. F. LYMAN

The inactivation of histamine. C. H. BEST AND E. W. MCHENRY. *J. Physiol* **70**, 349-72(1930).—The destructive agent, which is in highest concn. among the tissues of the dog in kidney and intestine, appears to have the properties of an enzyme; the name *histaminase* is suggested. Histamine seems to be destroyed by it through a change involving rupture of the imidazole ring.
J. F. LYMAN

A physicochemical theory of the action of substances on living matter. P. LAZAREV *J. chim. phys.* **28**, 42-8(1931).- It is assumed that the functions of a cell depend on the concn. of the material introduced C_0, and that the sensibility E can be expressed in such measurable quantities as rate of oxygen consumption, speed of nervous reaction, etc. The equation $E = E_c + E_1 \beta C_0(1 - e^{-\alpha t})$ is derived to show the sensibility of the cell at time t, where β is the ratio of the diffusion rate into the cell to the rate out of the cell, the latter being α. The equation is applied to the action of Et_2O on assimilation by chlorophyll and to the action on the nervous centers of substances introduced into the blood.
J. G. MCNALLY

The action of monochromatic light. GUIDO GUERRINI. *Boll. soc. ital. biol sper* **5**, 1098-1100(1930); cf. *C. A.* **25**, 534.—The action of light filtered through colored plates on *S. cerevisiae* in the presence of glucose was studied. The amt. of CO_2 liberated as a function of time was: max. for light filtered through red plates; slightly less for light filtered through yellow plates; still less for light filtered through green plates; and nothing or almost nothing for light filtered through blue plates. Light rays of long

wave length therefore stimulate the action of *S. cerevisiae* in the presence of glucose. PETER MASUCCI

Alcoholic fermentation in liver. VIRGILIO MARTINI. *Boll. soc. ital. biol. sper.* **5**, 1172–5(1930).—Liver pulp, strongly acidified with HCl (0.6–0.7%), and incubated at 37°, undergoes alc. fermentation with the formation of CO_2 and EtOH. The fermentation is caused by some thermolabile factor. PETER MASUCCI

Precipitation of animal proteins. GEORG GRASSER *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. II, 227–42(1930).—The behavior of solns. of gelatin and egg albumin with a large no. of phenols, naphthols, aldehydes and inorg. salts is tabulated. H. B. MERRILL

Electrokinetic phenomena. III. The "isoelectric point" of normal and sensitized mammalian erythrocytes. HAROLD A. ABRAMSON. *J. Gen. Physiol.* **14**, 163–77 (1930); cf. *C. A.* **24**, 5568.—Published isoelec. points of certain mammalian erythrocytes derived from studies of electrophoretic mobilities are the result of equil. incidental to erythrocyte destruction. This is a study of the mobilities of washed sheep and human erythrocytes in 0.85% NaCl soln. at p_H 3.6 to 7.4 made in 2 min. after prepn. of the suspensions. Under these conditions reversal of the sign of elec. charge did not occur; it occurred only after time had elapsed for the adsorption of the products of red cell destruction. Mobility changes little with decrease of p_H. The reversal of the sign of the charge occurs in the presence of normal and immune (anti-sheep) rabbit sera. The isoelec. point detd. under these conditions is apparently not specifically connected with the immune body but may be incidental to red cell destruction and the presence of serum. The characteristic lowering of mobility by amboceptor, however, occurs from p_H 4.0 to 7.4. The identity of the isoelec. points for normal and sensitized sheep cells is apparently not concerned with the immune reaction. Red cells are probably not covered with a film of albumin or globulin. Serum protein reacts with red cells in acid soln. whereas gelatin does not. Lowering of mobility, usually ascribed to anti-sheep rabbit serum, may also occur, but to lesser degree, in normal rabbit serum. This diminution of mobility is not assocd. with sensitization to hemolysis induced by complement. Only a very small part of the surface of the red cell need be changed to obtain complete hemolysis in the presence of complement. C. H. RICHARDSON

The kinetics of penetration. III. Equations for the exchange of ions. W. J. V. OSTERHOUT. *J. Gen. Physiol.* **14**, 277–84(1930); cf. *C. A.* **24**, 5318.—This is a preliminary attempt to outline the math. treatment of an exchange of ions between the interior of a living cell and the external soln C. H. RICHARDSON

The reversion of protein hydrolysis. A. SARLUY *Arch. néerland. physiol.* **16**, 136–44(1931).—The idea of Wasteneys and Borsook that such simple aromatic compds as benzene, toluene, xylene, benzoic acid or benzaldehyde when added to peptic protein hydrolyzates synthesize proteins is not held by S. It is his belief that the addn. of BzH to these hydrolyzates forms Schiff's base and that the addn. of benzene, toluene and xylene is merely an adsorption phenomenon M. H. SOULE

The action of muscle phosphatase, cozymase and insulin. J. BODNÁR AND B. LANKÓ. *Magyar Orvosi Arch.* **31**, 105–31(1930); cf. *C. A.* **25**, 1889.—The amt. of esterified phosphoric acid increases remarkably if the phosphate concn. is increased; 0.25 g muscle powder (prepd. by Euler's method, from pigeon breast) esterified in max. 11.42 mg. P_2O_5 (4.57%). The original muscle powder is not affected by boiled muscle juice. Muscle powder washed with H_2O at room temp. inhibits considerable of its activity, which is due to the want of cozymase, since the boiled juice increases the phosphoration of the washed powder in the presence of higher phosphate concn. Washed muscle powder esterified 0.63%, washed muscle-powder plus boiled muscle juice 2.03% P_2O_5. The boiled muscle juice not only increases the esterification of the washed muscle powder but it has the power of counteracting the lowering of the optimum caused by the injury of the phosphatase. Boiled yeast juice also has the power of reactivating the esterification of the washed muscle powder. Fresh muscle paste loses its activity in a few hours, but the dry powder keeps rather long. In 5 weeks only 20% of its activity is lost. Insulin has no effect on the power of phosphoration either in fresh muscle paste or in muscle powder. H. TAUBER

Thermal **disaggregation of gelatin** (GERNGROSS, *et al.*) **2.** Chemical decomposition by radiation (HARKER) **3.** A new physicochemical explanation of the formation of humus, peat and coal. NEEDHAM, JOSEPH: **A Chart to Illustrate the History of Biochemistry and Physiology.** Cambridge, Eng.: the author. 2 charts. Paper, 10s. 6d. Reviewed in *J. Am. Med. Assoc.* **96**, 1100(1931).

Vegetable albumins. HENRI A. BEAUFOUR. Fr. 695,233, Aug. 30, 1929. Colloidal solns. of the albumins are treated in a salt medium by dialysis and ultrafiltration in 2 successive phases. The 1st phase consists in the use of the phenomenon of dialysis and osmosis or electrodialysis and electroösmosis an ultrafilter membrane of medium porosity is used as dialyzing membrane. Between the 2 phases a large part of the albumin is sepd. by hypercentrifugation; this process depends on the change of mol. state provoked by the dialysis. Cf. *C. A.* **24**, 5951.

Enzymes. ALBERT R. BOIDIN and IVAN A. EFFRONT. Fr. 37,420, May 23, 1929. Addn. to 670,099 (*C. A.* **24**, 2007). The p_H of worts fermented to obtain proteolytic enzymes of high power is corrected during this fermentation as often as necessary by the addn. of compds. of alk., acid or amphoteric reaction.

Enzymes. I. G. FARBENIND. A.-G. Ger. 515,931, Feb. 18, 1928. Enzymes are prepd. by treating the starting material such as milk, latex, etc., with proteases of p_H about 7, sepg. the coagulation product and isolating the enzymes therein in the usual manner. Cf. *C. A.* **24**, 4186.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

A simplified method for quantitative tissue culture in vitro. MACHTELD SANO AND LAWRENCE W. SMITH. *Proc. Soc. Exptl. Biol. Med.* **28**, 282–4(1930).—The tissue is grown in media contained in a special chamber consisting of a Pyrex glass ring 3 in in diam., 5–6 mm. high, with parallel flat ground surfaces, 2–3 mm. in thickness. Thin sheets of mica 3¼ in. in diam. form the top and bottom of the chamber; they are held in place by rims of petrolatum. The chamber is kept in a 4 in. Petri dish. The method permits the examn. of the growing tissue with high-power microscopic objectives, quant. growth is possible and the tissues may be fixed and stained without distortion.

Micro method for the determination of cystine in proteins. A. D. MARENZI *Compt. rend. soc. biol.* **104**, 405–7(1930).—See *C. A.* **24**, 5049. E. J. C.

The methylene-blue staining of yeast cells and studies on the permeability of the yeast-cell membrane. I. HERMANN FINK. *Z. physiol. Chem.* **195**, 215–40(1931), cf. *C. A.* **24**, 4354.—A crit. study was made of the methylene-blue-staining method commonly employed for distinguishing between living and dead yeast cells, and also a study of the permeability of the cell membrane. Both the quantity of dye taken up by the yeast and the no. of cells stained depend on the p_H. For one and the same yeast quite different values may be obtained for the no. of "dead" cells according to whether the yeast is taken directly from the fermented substrate or given a subsequent treatment with tap water. The influence of salts on the methylene-blue staining is still more important. In distd. water the no. of stainable cells rapidly increases while in tap water it remains practically const. during the same period of time. This difference becomes enormous when sugar is also present. In a few min. as many as 98% of the cells in the salt-free sugar soln. are stained deep blue, while in tap water the presence of sugar has little influence. This result is not to be interpreted in the sense of the methylene-blue method as the death of the cells, but must be considered from the standpoint of a change in permeability of the cell membrane. By the brief sojourn in an electrolyte-free sugar soln. the cells or their membranes are so altered that the methylene blue can penetrate. These cells thus prepd. for the reception of dye and easily stained deep blue are sound and capable of proliferation. They are not killed until the dye has actually penetrated. The predisposition to reception of dye can be completely removed again by a small addn. of salt. The same phenomena are evoked equally by glucose, fructose, sucrose and galactose; maltose is somewhat less effective. They are more pronounced with brewer's yeast than with baker's yeast. The results were confirmed and extended in eudiometer expts. In electrolyte-free mixts the fermentation velocity was less than in the presence of salts. If methylene blue was also present in the system the fermentation was strongly inhibited. This inhibition is almost completely overcome by salts, the activity of their ions following essentially the order of the Hofmeister series.

F. L. DUNN

The chemical detection of adrenaline in the blood. G. VIALE. *Boll. soc. ital. biol. sper.* **5**, 1163–7(1930).—To 1 cc. of blood add 1 cc. of satd. $HgCl_2$ acidified with traces of HCl (p_H = 6). Filter; add to the filtrate a few drops of satd. sulfanilic acid and satd. KIO_3 soln.; boil. The soln. develops a rose color. The reaction is always pos. with blood; occasionally with lymph; neg. with cerebrospinal fluid. The reaction is not given by urea, uric acid, tyrosine, tryptophan, indole, cholesterol, ephetonine, nor by the products of acid hydrolysis of egg white. Animal expts. indicate that the reaction is given by adrenaline. Since the blood of dogs deprived of the suprarenal capsules also gave a pos. reaction, the hypothesis is advanced that the reaction is also given by precursors of adrenaline, substances contg. the pyrocatechin group. The reaction may be used as an index of the amt. of adrenaline in the blood, by estg. the quantity colorimetrically. It is sensitive in a diln. of 1 to 30 million.

PETER MASUCCI

Preferred methods for the clinical determination of glucemia. LUIGI PINELLI AND ATTILIO CORBIA. *Biochim. terap. sper.* **18**, 19–33(1931).—The methods of Folin-Thivolle, Hagedorn, Hartmann-Schaeffer, Ionesco-Matiu and Bertrand-Silvestri are described and the results compared. Generally, the methods based on the reduction of Fe salts give higher results than the Cu methods. The av. figures for normal persons by the method of Folin are 0.085, by Hagedorn 0.135, Ionesco 0.162, Schaeffer 0.076 and Bertrand 0.085%. The av. in diseases was 0.088, 0.105, 0.157, 0.085 and 0.094, resp. The Ionesco method gave in some cases results 4 times as high as those by the Folin method.

Determination of albumin according to Esbach. J. VÁSÁRHELYI. Hun. 101,531, Dec. 21, 1929. Esbach tubes that can be used in centrifuges are specified. They reduce the time required for the detn. to a few min. instead of 24 hrs.

C—BACTERIOLOGY

CHARLES B. MORREY

Microbic dissociation with reference to the attenuated tubercle bacillus of Calmette and Guerin (B. C. G.). R. S. BEGBIE. *Edinburgh Med. J.* **38**, 174–82(1931).—Evidence is presented for the dissocn. of B. C. G. into intermediate, rough and smooth types. By guinea-pig inoculation the virulence is found to increase in the order named. A fresh culture of B. C. G. on glycerol bile potato medium is less virulent than a subculture on Dorset's egg medium.

RACHEL BROWN

Experimental and applied studies in electrosterilization. I. LOUIS I. GROSSMAN AND J. L. T. APPLETON, JR. *Dental Cosmos* **73**, 147–60(1931).—With oral bacteria and a clinically tolerated dosage of current (30 ma.-min.), greater antibacterial effect was uniformly obtained from an electrolyzed soln. than from the same soln. without electrolysis. The antibacterial effect always was greater at the anode. ZnI_2 was more efficient than KI. Of approx. 50 solns. tested, the greatest antibacterial effect compatible with tissue tolerance was given by 1 *M* ZnI_2 in 0.1 *M* I; this soln. had no greater irritant action than 0.85% NaCl soln. The action exerted was bactericidal and due directly to the action of the electrolyzed compd., and not to a change in the reaction of the medium. **II. Relative antibacterial effects of different electrodes used in electrosterilization.** *Ibid* 250–3.—The antibacterial effect depended upon both the electrode and the electrolyte. With NaCl as the electrolyte, a Zn electrode gave a greater antibacterial effect than an Ir-Pt electrode. With either $ZnCl_2$ or ZnI_2 + I_2, both types of electrode gave similar results. As electrode material Wipla steel was more efficient than Pt, less efficient than Zn. Both Zn and Zn-coated electrodes were slightly corroded by 1 *M* ZnI_2 in 0.1 *M* I, while an Ir-Pt electrode was unaffected. **III. Single- and multiple-electrode studies.** *Ibid* 370–3.—The antibacterial effect from a single electrode is greater than that from each of the 2 or 3 electrodes constituting a multiple electrode. Each constituent of a multiple electrode has practically the same effect.

JOSEPH S. HEPBURN

Theories of the bacteriophage. JULES BORDET. *Proc. Roy. Soc.* (London) **B107**, 398–417(1931).—The bacteriophage is not a virus, but its intense action represents

merely the pathol. exaggeration of a normal function connected with mutation, the lysis being a transmissible autolysis. JOSEPH S. HEPBURN

Modification of the Morse-Kopeloff culture of anaerobes. ARAO ITANO AND SACHIO ARAKAWA. *J. Agr. Chem. Soc. Japan* **6**, 996-8(1930).—A mixt. of 0.5–1.0 g. pyrogallol and 10–15 cc. 10% KOH was put in a Petri dish, and covered by another dish with agar culture medium. The dishes were sealed with Toma tape. This is a convenient method for the culture of *Clostridium pastorianum* and of thermobacteria at 60–5°. Y. KIHARA

The influence of soaps on the germicidal properties of certain mercurial compounds. BETTYLEE HAMPIL. *Am. J. Hyg.* **13**, 623–37(1931).—The presence of Na oleate or a mixt. of soaps such as Lux in concn. of 1% or over greatly increases the toxicity of $HgCl_2$ to virulent staphylococci at 37°. Smaller quantities of soap gave varying results; large amts. were no better than 1%. Destruction of the bacteria occurred in 5 min. The fact that there is no toxicity is not due to increased absorption due to the soap influencing the membrane, for it makes no difference whether the soap and the mercurial are used together or in any order. Some other organisms were not affected by the soap and for some its presence was protective. Soap increases the action of $HgBr_2$ and $Hg(NO)_2$ in some instances, particularly for *Staph. aureus*. The toxicity of $Hg(CN)_2$ and *o*-chloromercuriphenol is increased 3 to 4 times by soap. G. H. W. LUCAS

Germicidal efficiency of soaps and of mixtures of soaps with sodium hydroxide or with phenols. J. M. SCHAFFER AND F. W. TILLEY. *J. Agr. Research* **41**, 737–47 (1930).—Coconut-oil soap is the only common soap with significant germicidal activity at room temp. Its activity against most of the organisms tested is comparatively low but in the absence of org. matter it manifests a very high germicidal activity against *Pasteurella avicida* and *P. suiseptica* and some strains of hemolytic streptococci. In the presence of org. matter, however, its activity toward these organisms is relatively low. The addn. of NaOH to solns. of neutral coconut-oil soap increases the effectiveness of the solns. against the various bacteria tested. Coconut-oil soap, castor oil soap or linseed-oil soap when mixed with various phenolic compds. in the proportion of 1 part of soap to 2 parts of phenol considerably increased the germicidal efficiency of the phenols in the absence of org. matter. In the presence of milk or blood serum such increases were comparatively small. Germicidal soaps made by adding cresol, commercial cresylic acid or orthophenylphenol to coconut-oil soap are efficient against *Staphylococcus aureus* even in the presence of milk or blood serum. There is no satisfactory explanation of the germicidal activity of soaps, or of their action in enhancing the germicidal activity of phenols. W. H. ROSS

THOMAS G. PHILLIPS

Changes in the phosphorus content of growing mung beans. JAMES E. WEBSTER AND CLAUDE DALBOM. *J. Agr. Research* **41**, 819–24(1930).—A study of the P content of the various aerial organs of the mung bean as the plant grew to maturity shows that the stems and branches have a greater proportion of total inorg. P than is found in the leaves. The decrease in total P is much larger than the decrease in ash content. There is a relatively small change in the amt. of inorg. P in any one organ as the plant matures. There are indications that the P taken into the plant is metabolized to org. forms for storage. Lipoid P constitutes only a small fraction of the green plant and changes little during growth. There is only a slight change in the total P content at harvest times, so that differences of 2 or 3 weeks would make only negligible changes in the P feeding value. There is no evidence that P is transferred from the leaves and branches to the stems, and it is assumed that the localization of P follows the normal ash intake and is not the result of metabolic activities. J. R. ADAMS

The chemical composition of Ambrosia trifida at successive growth stages. R. B. DUSTMAN AND L. C. SHRIVER. *J. Am. Soc. Agron.* **23**, 190–4(1931).—The crude protein, N-free ext. and ash content of *Ambrosia trifida* are high well up to the time of

bloom while the fiber is correspondingly low. This plant might be made to yield considerable amts. of forage of high nutritive value because of its leafy nature and the high N content of the leaves. J. R. ADAMS

Guttation and its relationship to nitrates and other salts in the nutrient medium. A. DRAGHETTI. *Ann. staz. sper. agr. Modena* [N. S.], 1, 123–32(1930).—Wheat plants were cultivated on nutrient media contg. several salts, and the quantity of liquid obtained by guttation was measured. This quantity always reaches a max. in the 4th or 5th day of culture. When the nutrient soln. contains Ca, Na, NH_4 or K nitrates, the guttated liquid gives the nitrate reaction, but when Ba or Sr nitrates are present, the NO_3 reaction is not obtained. G. A. BRAVO

Morphological, biometrical and chemical notes on the cherries cultivated in the Modena Province. G. D'IPPOLITO AND E. ALBERTI. *Ann. staz. sper. agr. Modena* [N. S.], 1, 189–202(1930).—The chem. analyses of the cherries made by Berard, Fresenius and Richardson are given (without bibliography) and the morphological characters of 11 varieties of cherries (derived from *Cerasus avium* L.) are described. G. A. B.

Effect of turbulence (of the atmosphere) on the carbon-dioxide exchange in plants. P. LEHMANN. *Fortschritte Landw.* 4, 745(1929).—Variations in the CO_2 content of the air at short intervals and under varying conditions are recorded. The effect of wind velocity, temp. and environmental conditions on local changes in the moisture and CO_2 contents of air and the resulting influence on the CO_2 assimilation of plants, are discussed. B. C. A

Cyanogenetic glucosides in Australian plants. II. (a) Eremophila maculata. HORACE FINNEMORE AND CHARLES BERTRAM COX *J. Proc Roy. Soc. N S. Wales* 63, 172–8(1930).—Prunasin (cyanogenetic glucoside) has been isolated from the bark of *Prunus serotina*, and its identity with the glucoside now isolated from *Eremophila maculata* has been confirmed by the mixed m.-p. method **(b) Presence of enzymes in fodder plants as a factor in the poisoning of stock.** SUZANNE K. REICHARD. *Ibid* 179–82(1930).—The isolation of sambunigrin and prunasin has afforded the opportunity of testing, by means of these cyanogenetic glucosides, for the presence of enzymes in plants capable of decompg. them, and liberating the HCN which they contain. Investigation of *E. maculata* showed that the sample of dried plant employed contained practically no enzyme, and that, therefore, only a trace of HCN was liberated, and, in spite of the presence of an exceptionally large amt of glucoside, there still remained some doubt whether this plant was poisonous or not. Another plant, *Heterodendron oleaefolium*, recently submitted for examn., similarly contained a large amt. of cyanogenetic glucoside, but insufficient enzyme to give a positive reaction until enzyme from another source had been added. In this particular case it has been recorded by Petrie that only 1/3 the amt. of acid was liberated before the addn of enzyme (emulsin). Some of Petrie's work has been repeated, notably that involving amygdalin and its splitting enzyme β-amygdalase. The case with which prunasin and sambunigrin are decomposed, as compared with amygdalin by the enzymes of plants, is shown, and the significance of the presence of enzymes in fodder plants is illustrated W. O. E.

Membranes of spores and pollen. II. Lycopodium clavatum L. 2. FRITZ ZETZSCHE AND HANS VICARI. *Helv. Chim. Acta* 14, 58–62(1931); cf. *C. A.* 22, 2949.—The sporenin from lycopodium spores previously described was not free from cellulose and ash The cellulose could not be entirely removed by Schweitzer's cuprammonium reagent Treatment with 85% H_3PO_4 gave a cellulose-free product; so did 75% H_2SO_4 but some sulfonation took place Ash was reduced to < 0.2% by concd HF. Hydroxyl groups were detd. by acetylation. The formula is fixed as $C_{90}H_{127}O_{12}(OH)_{15}$. The yield was 23.8% of the spores. **III. 2. Picea orientalis, Pinus silvestris L., Corylus avellana L.** *Ibid* 62–7.—Qual. tests on many pollens showed that their hulls or membranes are similar chemically to lycopodium-sporenin, and the name *pollenin* is proposed for such compds. Three were isolated by treating the pollen successively with volatile solvents, KOH, H_3PO_4 and HF, and their formulas detd. as: *Picea* pollenin, $C_{90}H_{146}O_{25}$; *Pinus* pollenin, $C_{90}H_{144}O_{24}$ or $C_{90}H_{131}O_{11}(OH)_{13}$; *Corylus* pollenin, $C_{90}H_{188}O_{22}$. The yields were, resp., 21.9, 20.0 and 7.3% of the pollens. **IV. 3. Fossil sporopollenins from Tasmanite and Russian lignite.** FRITZ ZETZSCHE, HANS VICARI AND GUSTAV SCHÄRER. *Ibid* 67–78.—Fossil spores and pollens have been found in many coals and oil shales. Selected specimens of a Tasmanian oil shale, tasmanite, were ground and the organic material was sepd from the sand by floating on CCl_4. Clay was removed by shaking with soap soln. The crude sporopollenin, *i. e.*, mixt. of spore and pollen membranes, obtained was purified as previously described. The yield was 17% of a substance with the probable formula, $C_{90}H_{134}O_{18}(OH)_2$, for which the name *tasmanin* is proposed. From a lignite from the Tschulchowsky deposits near Skopin

8.5% of a fossil sporenin, $C_{10}H_{11}O_{12}(OH)_6$, was isolated. This is believed to be derived from macrospores of the genus *Bothrodendron;* hence the name *bothrodendrin* is proposed for the compd. A S-contg. sporenin was also present. Recent lycopodium sporenin and fossil bothrodendrin dissolve in concd. HNO_3 in 12–24 hrs. at room temp.; tasmanin requires 3 weeks. This is attributed to the decreased no. of OH groups making it more paraffin-like in character. L. E. Gilson

Biochemistry of tomato pigment. H. von Euler, P. Karrer, E. von Krauss and O. Walker. *Helv. Chim. Acta* **14**, 154–62(1931).—Green tomatoes kept at 20–1° ripened normally in a few days, developing the usual red lycopin coloring. At 30° they developed only a yellow color. Tests showed carotene, xanthophyll and an unidentified yellow flavone dye but no lycopin. At 37° they turned yellow and spoiled rapidly. Light, or its absence, has no effect on the rate of coloring. It is believed that lycopin is formed by an enzyme action which is inhibited by the higher temp. The pigment of the naturally yellow variety of tomato, "Golden Queen," was studied. Dried skins from vine-ripened fruit contained 0.021 g. carotene and 0.0053 g. xanthophyll per kg. but no lycopin. A considerable amt. of a yellow flavone dye, insol. in CS_2, sol. in alk., was also present. This has not yet been identified

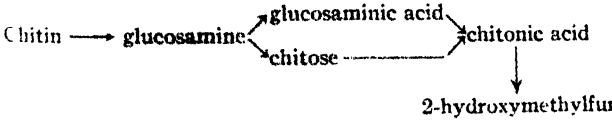
L. E. Gilson

The significance of iodine in (plant and) human metabolism. J. Stoklasa *Z. Ernähr.* **1**, 3–15(1931).—I is absorbed by many plants in comparatively large quantities and changed to org. I. The I-satd. plants have an important pharmacol. significance and can well be used in place of org. I. The I aids the oxidation processes in plants and animals and hinders a rise in H-ion concn. in the individual organs. *The I absorbed by plants* accumulates chiefly in the chlorophyll-rich portion of the plant. For expts. on the absorption of I by plants and its distribution in org. and inorg. form, the following data are given. The p_H of the soil was 6.68–7.36 High org. and inorg. soil I were closely correlated with high org. and inorg. plant I in the cases of *Cucumis sativus, Solanum lycopersicum, Raphanus sativus, Rheum undulatum* and *Spinacea oleracea* For example, the fruit of *Cucumis sativus* gave 1300 parts per billion of total I with a soil content of 236; and 2600 parts per billion with a soil content of 859. The p_H values of the juices from the roots of various plants are given. By I fertilization the p_H is raised. The author, after 14 days on a diet of plants high in I, noticed a lowering of the H-ion concn. of the urine from p_H 4.8 5.2 to 5.6 6.2. By the feeding of silk worms with leaves high in I a 65–85% increase in the no. of eggs laid was obtained Thirty-three references are given. Francis P. Griffiths

Organic matter given off by algae. August Krogh, Eugen Lange and Willi. Smith. *Biochem. J.* **24**, 1666–71(1930). —Culture expts. show that the org. material synthesized by the assimilation of freshwater algae is almost quantitatively stored in the cells of the algae. Benjamin Harrow

Determination of maltose in plant extracts by maltase. Nadigar Narasimhamurty and Motnahalli Sreenivasaya. *Biochem. J.* **24**, 1734–6(1930).—The enzyme ext. was prepd. from finely ground brewer's yeast desiccated over P_2O_5 by treating the material with 10 parts of a 5.8% soln. of Na phosphate at 20° for 14 hrs. The ext was centrifuged for 10 min., the filtrate neutralized to litmus with 4% KH_2PO_4 and preserved at 0°. This maltase ext. can be used for estg. maltose in mixts. of sugars occurring in plant exts. and tissue fluids. Benjamin Harrow

Accumulation of electrolytes in plant cells. A suggested mechanism. G. E. Briggs. *Proc. Roy. Soc.* (London) **B107**, 248–69(1930).—"A possible scheme, based on alternating phases, one of greater permeability to anions and the other of greater permeability to cations, is suggested to explain the accumulation of ions." J. S. H.



Alteration of the iron in chloroplasts due to chemical treatment. Hans Griessmeyer. *Planta, Abt. E., Z. wiss. Biol.* **11**, 331–58(1930).—When leaves of certain cereal plants were exposed in darkness to such vapors as SO_2 and fuming HNO_3 and to solns. of KCN and NH_4CNS the sol. Fe in the plastids increased at the expense of the insol. Fe. Plasmolytic tests with KNO_3 immediately after treatment showed that the leaf cells had not been killed. In contrast, treatment with ether and phenylurethan failed to increase the sol. Fe. Placing leaves in an Fe soln. increased the Fe content of the plastids. Leaves lacking a normal green color due to etiolation, variegation or to lack of Fe all contained a normal amt. of Fe in the plastids. But after treatment with the chemicals previously mentioned, these abnormally colored leaves behaved the same as normal green leaves in regard to an increase in sol. Fe. These results are offered as direct evidence for the participation of Fe in photosynthesis. A. E. H.

Experiments on the influence of iron salts on the pigments of chlorophyll. T. N.

GODNEV, S. K. KORZHENEVSKII AND M. H. GONCHARIK. *Ann. Weissruth. Staatl. Akad. Landw. Gory-Gorki* 9, 126–35(1929).—In expts. with *Pisum sativum* in culture solns. it was found that there was no proportional relation between the Fe taken up from the soln. and the coloring matter in the plants as was the case in maize. Fe is not of immediate importance for the building of chlorophyll; it is rather important primarily in the metabolic activity of the plasma. Fe enters as a constituent part of the chlorophyll mol.
J. S. JOFFE

Limiting factors in photosynthesis. V. A. CHESNOKOV AND E. N. BAZUIRINA. *Comp. rend. acad. sci. U. R. S. S.* No. 8, 193–8(1930A).—Ch. and B. analyze the theory of Blackman (*Ann. Botany* 19, 28(1905) and *Proc. Roy. Soc.* (London) B76, 402(1905)) on the influence of direct and indirect factors on photosynthesis as it is based on the Liebig law of minima. They question the character of the optimum curve as expounded by Blackman. An increase in the temp. of the medium which surrounds the leaf, according to Blackman, causes a series of changes in photosynthesis. Two groups of changes are noted; one corresponds to an increase in photochem. activity following the van't Hoff reaction. The other one has to do with some processes in the plasma. Both influences take place simultaneously and the curve is a result of that. They point out that the temp. of the leaf itself and not the external temp. of the medium is responsible for the thermal increase in reactivity. In general they consider that all the factors in photosynthesis are nothing more than indirect factors. From the expts of Warburg and Negelein (cf. *C. A.* 16, 3929–30) it is apparent that the coeff. of utilization of light is very high even with a small light intensity, which shows that light influences other processes which in turn change the velocity of photochem. reactions. As an increase in the temp. of the leaf takes place, there is an increase in transpiration, dehydration of the plasma, a change in the penetration of CO_2 in the plasma, etc The only rational way of investigating external factors is to det. the direct limiting factors. Such factors may be found in the internal system of the plant. They criticize the work of Lundegårdh on the effect of CO_2 concn. and intensity of light on photosynthesis. They do not consider the CO_2 or light as the limiting factors. It is the velocity of the penetration of CO_2 in the plasma that is responsible for the changes observed. They explain Lundegårdh's expts. as follows: Under the influence of light an increase in the penetration of CO_2 in the protoplasm takes place. This causes the chloroplastids to take up more moles of CO_2 and photosynthesis is speeded up. The same takes place with an increase in the concn. of CO_2. Thus the min. is the CO_2 entrance in the plastids. They prove their point with the results described by Warburg. They conclude that Lundegårdh's new theory does not overthrow the fundamentals of Blackman, if the latter's theories are analyzed in the light of the authors' contention that it is the internal influences which are responsible for the behaviors noted. J. S. JOFFE

The fermentation products of molds. VIII. Aspergillus glaucus. YUSUKE SUMIKI *J. Agr. Chem. Soc. Japan* 6, 1153–65; *Bull. Agr. Chem. Soc Japan* 6, 105–6 (1930); cf. *C. A.* 24, 3812.—In the culture of *A. glaucus* 2 hydroxymethylfuran-5-carboxylic acid (m. 163°) was produced and identified as the mono-Ac deriv. (m. 115°). It was not obtained in the culture solns. of gluconic acid and hydroxymethylfurfurol, but glucosamine, glucosaminic acid and chitose or chitonic acid were. The source of 2-hydroxymethylfuran-5-carboxylic acid may be chitin in the mold.

Y. KIHARA

Phytin and the methods of its preparation. N. E. ZELIGSON. *Trans. Sci. Chem.-Pharm. Inst.* (Moscow) No. 23, 4–81 (in German 82–3)(1930).—A monograph contg. a review of the literature, a restatement of the most reliable methods for the estn. of the constituent element of phytin and a description of a new method for the double combustion of C. A new method is offered for the estn. of the mineral phosphoric acid in phytin by pptn. with molybdic soln. in the cold. The following detns. were made: total phosphoric acid, mineral phosphoric acid, phosphoric acid added to phytin previously freed from mineral phosphates, phosphoric acid in org. combination, C and H, bases (Ca and Mg, Na and K, NH_4), Fe and Mn, Na and moisture. Analysis of several samples of phytin and a study of the Ba, Ca, Na, strychnine and borax salts of inositol phosphoric acid were made. Inositolhexaphosphomolybdic acid was given

some consideration analytically. Summaries in Russian and in German are appended.
B. S. LEVINE

Physico-chemical studies of rice produced in Gifu province. HANNEMON ITO, TATSUO WATANABE AND MASUO KITAHARA. Gifu Imp. Coll. of Agr. (Japan), *Research Bull.* 13, 48 pp.(1930).—Rice with high protein content is generally harder. The protein content of rice of poor quality is generally high, but grain of superior quality is high in fat. The fat of rice varieties adapted to growth in colder regions is higher in acid value than the varieties requiring warmer climate. Elementary analyses of the glutelin and globulin of rice showed the following values:

	C %	H %	N %	S %	Ash %	Isoelectric point, p_H
Glutelin	50.6–53.3	7.0–7.7	16.5–17.3	0.53–0.64	0.31–0 79	6.2–5.0
Globulin	50.8–52.5	7 0–7.6	16.5–17.3	0.44–1.15		5.5–4 6

K. KITSUTA

The role of iron and copper in the growth and metabolism of yeast. C. A. ELVEHJEM. *J. Biol. Chem.* 90, 111–32(1931).—The yeast was grown in a modified Wildiers medium, the constituents of which were purified so that they were practically Fe and Cu-free. Addn. of a small amt. of Fe accelerates the rate of yeast growth, increases the cytochrome content to the amt. normally present in com. yeast, and increases the respiratory quotient to Q_{O_2} values of 35–40. Addn. of both Cu and Fe causes a further increase in the growth rate and the production of cytochrome with a distinctly higher *a* component. Cu has the property of stimulating the formation of certain hematin compds. 0.02 mg. of Cu per 200 cc. of medium is the optimum amt for stimulating the formation of cytochrome *a* and additional amts. inhibit cell growth during the 1st 48 hrs. The toxic effect disappears as the no. of cells per unit of medium increases. The ratio of available Fe to the amt. of yeast present determines the Fe content of the yeast. Yeast low in inorg. Fe is unable to assimilate Fe from a phosphate buffer at p_H 7.0 but readily takes up Fe at p_H 4.0. Thus, the availability of Fe may be the limiting factor in many of the synthetic media which have been used for studying the growth requirements of yeast, Q_{O_2} values of 35–40 in 48-hr. cultures decrease to 15–20 when the culture is 6–7 days old because of the high acidity of the medium. At least 80% of the respiration is inhibited by KCN at 48 hrs. of age but the KCN-labile portion gradually decreases and after 7 days the O_2 uptake is completely unaffected by KCN. The KCN-stable system metabolizes glucose, is destroyed by heating to 60° and is inhibited by urethan to the extent of 70%. The respiration of yeast grown on beer wort, which prevents the development of high acidity, is largely inhibited by KCN. The total respiration of yeast grown on wort may be low on account of an insufficient supply of Fe in the beer wort. Bios stimulated the growth rate to a small extent but had no effect on the respiratory activity. The activity of bios is not so noticeable when the medium is maintained at the proper p_H. Further work will be required to det. whether the effect of bios can be eliminated entirely by regulation of acidity or whether it actually stimulates yeast growth but in either case the effect will be closely associated with the availability of the Fe. Bibliography of 23 references.

The non-volatile organic acids of green tobacco leaves. HUBERT B. VICKERY AND GEORGE W. PUCHER. *J. Biol. Chem.* 90, 637–53(1931); *Connecticut Agr. Expt. Sta. Bull.* 323, 155–202.—The existing methods for the *detn. of the org. acids in plant tissues* have been so modified as to make possible approx. quant. isolation and positive identification of the predominating acids. The acids are initially pptd. as Ba salts in the presence of dil. alc. rather than as the Pb salts by basic Pb acetate. In tobacco leaf exts. only about ½ of the total titratable acidity consists of acids of the familiar types such as malic, citric, succinic and fumaric. The remainder is due to acidic substances, the nature of which has not been detd. although part appears as phenolic acids. On account of the presence of these substances, indirect methods for the detn of oxalic, citric and malic acids, such as those of Kissling and of Fleisher, do not yield trustworthy results. Bibliography of 29 references.
A. P. LOTHROP

Causes of unequal resistance of a vine to mildew. L. RIVES AND G. KALÉ. *Prog. agr. vit.* 95, 138–9(1931).—An examn. of the f. ps. of extd. juices of grape vine leaves, sampled in October, indicated no relation between their resistance to mildew and the concn. of their cellular juice.
F. W. MARSH

Variations in the osmotic pressure of certain Basidiomycetes. SYLVIA COLLA AND ZIPORA DANIN. *Boll. soc. ital. biol. sper.* 5, 885–7(1930).—The juice of *B. edulis*,

A. cesarea L., *C. cibarius* Fries and *Russulavirescens* Schäft was obtained by pressing and the Δ detd. The Δ varied from species to species; it varied during the development of the reproductive cells and decreased during maturation and when aged; it was not equal in all parts of the same fungus. PETER MASUCCI

Respiration of seeds from oil plants. A. I. ERMAKOV AND NICOLAI N. IVANOV. *Biochem. Z.* **231**, 79–91(1931).—The respiration of oil seeds during the early stages of germination does not differ from that of seeds contg. carbohydrate stores. The CO_2 production bears a ratio of 1:1 to the O_2 absorption of these oil seeds. Neither the quantity nor the quality of the oil changes in the first hrs. of germination, while the amt of sugar increases at the expense of polysaccharides undergoing enzymic hydrolysis. The fact that the I no. of the oil does not change leads to the conclusion that the oil is not directly oxidized by the O_2 from the air, carbohydrates being the material primarily used in the respiration. S. MORGULIS

The presence of a dihydroxyphenyl derivative and of a specific enzyme in the apple and other fruits. KARL SPITZER. *Biochem. Z.* **231**, 309–13(1931).—The presence of an *o*-dihydroxyphenyl deriv. has been established in apples, pears and other fruits, and its identity with dopa seems very probable. Also an enzyme has been found in these fruits which reacts in a sp. way on dopa but has no effect on tyrosine. The enzyme is attached to the tissues. The browning of the fruit is due to its action on the chromogen. S. MORGULIS

Relations existing between the different organic acids elaborated by Sterigmatocystis nigra. MOLLIARD. *Compt. rend.* **192**, 313–5(1931).—When *Sterigmatocystis nigra* is cultivated in media sufficiently low in minerals to insure the utilization of a given quantity of org. substance, org. acids are formed of which the most important are gluconic, citric and oxalic acids. From cultures grown for 90 days in a medium contg. sucrose and only $^1/_{25}$ of the normal amts. of mineral the following information was obtained: An appreciable amt. of reducing sugar remained at the end; at no time did oxalic acid appear; gluconic acid increased rapidly for 10 days, remained stationary from the 10th to the 60th day and then rapidly diminished; citric acid was not very abundant at the end of 10 days, but increased in concn. constantly throughout the entire 90 days. To det. whether citric acid is formed from gluconic acid a culture of *S nigra* was grown under conditions similar to those of the above expt., gluconic acid being used instead of sucrose as the base. The following results were obtained: No trace of citric or oxalic acids was formed; the polarimetric deviation remained proportional to the free acidity. Gluconic acid, then, acts as a nutrient in the same manner as glucose, but never gives rise to citric acid. Gluconic acid, like the sugars, gives rise to oxalic acid when the culture medium tends toward alky. Analogous conclusions are reached concerning citric acid. M. concludes that gluconic and citric acids must be considered as oxidation products of sugars because of inanition in mineral substances; they both may be utilized subsequently by the fungus, but citric acid cannot be formed from gluconic acid. Oxalic acid is incapable of being utilized by *Sterigmatocystis nigra* and must be considered a final excretion product. ALBERT L. RAWLINS

The influence of nickel compounds and of cyanides on the germination of grains. ANNELIESE NIETHAMMER. *Wiss. Arch. Landw., Abt A, Pflanze* **4**, 607–34(1930).—Grains of wheat were placed in vessels contg. H_2O, $NiSO_4$, $Ni(NO_3)_2$, $NiCl_2$, $NiCO_3$, $Ni(CN)_2$ 2KCN, KCNS, NaCNS solns. of 0.1, 0.5 and 1.0% and the germination was observed. Arranged in the order of injurious effects, the compounds rank $Ni(CN)_2 \cdot 2KCN > Ni(NO_3)_2 > NiCO_3 > NiCl_2 > NiSO_4$. 0.1% solns. of $Ni(NO_3)_2$ and $NiSO_4$ accelerate germination. It was not detd. whether the effect was due to physical or chemical changes, although histological examn. showed that the Ni solns. penetrated to the embryo as well as the endosperm. Wheat grains of the years 1921, 1923 and 1924 were similarly treated, and similar results were observed. The individual grains were then examd. quantitatively for acetaldehyde, starch, reducing sugar and protein. The same investigation was conducted on *Allium cepa*. W. GORDON ROSE

The algae flora of the Ruhr River. HERMANN BUDDE. *Arch. Hydrobiol.* **21**, 550–648(1930).—Numerous data on the compn. of the Ruhr water are included. The analyses comprised temp., transparency, color, sediment, reaction to phenolphthalein, H-ion concn., hardness, no. of germs and content of org. substance, Cl, HNO_3, HNO_2, NH_3, Fe, CO_2 and O_2. Large bibliography. G. SCHWOCH

The metabolism of mosaic-diseased and healthy tobacco plants. M. LÜDTKE. *Phytopath. Z.* **2**, 341–59(1930); *Rev. Applied Mycol.* **10**, 132–3.—Chem. analysis of healthy and mosaic tobacco plants showed that the accumulation of starch in the latter is not due to a disturbance or reduction of diastatic activity. A sucrose- and a pep-

tone-splitting enzyme displayed equal activity in healthy and mosaic plants. Gelatin was not split up by the leaf enzymes. The injection of isoamylene into tobacco plants did not produce symptoms resembling mosaic. No alteration was observed in the pectin substance of mosaic leaves as compared with those of normal plants. These data indicate that tobacco mosaic does not result from a disturbance of the enzymic activity. OLDEN E. SHEPPARD

The thermodynamics of ion concentration by living plant cells. F. PAUL ZSCHEILE, JR. *Protoplasma* 11, 481–96(1930).—Ionic strength and activity coeffs. are used to calc., thermodynamically, the free energy change of ion concn. by living cells of *Nitella* and *Valonia*. The radioactive energy of K^+ is inadequate to account for this change. The e. m. f. due to oxidation-reduction potential may be an important factor.
B. A. SOULE

Diffusion of certain solutes through membranes of living plant cells and its bearing upon certain problems of solute movement in the plant. FREDERICK C. STEWARD *Protoplasma* 11, 521–57(1930).—By use of a special cutting device, cylinders, 3.4 cm. in diam., of potato and beet were prepd. These were used as membranes for diffusion expts. involving various sugars and salts. Diffusion of solutes through the living tissue is much slower than in aq. soln. This is due to the resistance of the protoplasm. Whether the small amt. of diffusion occurring is through the cells or along the walls is not decided. Diffusion through maple or cherry bark does not increase with rise in concn. of solute as much as it does through potato or beet. B. A. SOULE

Influence of the reaction of the medium upon the germination of spores of certain species of Mucor. R. CESBRON. *Thesis.* Paris, 1929; *J. pharm. chim.* [8], 13, 33–4(1931).—With 6 species of *Mucor, viz., M. spinosus, M. circinelloides, Circinella spinosa, Absidia cerulea, Rhizopus nigricans* and *Cunninghamella echinulata*, the influence of the reaction of the medium upon the germination of spores was studied by the method of hanging drops under minutely defined working conditions; the source of N of the media was of varied nature. On the alk. side, extreme limits have not been noted; even at p_H = 9.8 germination was still abundant with several species. On the acid side, germination stops near p_H = 3 although the limit is about 3.5 or 4 when the source of N is an NH_4 salt, and 2.5 when the source of N is an alk. nitrate, an amino acid or peptone. The resulting curves denoting percentage of germinated spores as a function of p_H show a double max. sepd. by a sometimes very pronounced min.; the min. is observed in all media and with all species. It is important that the drops examd. shall contain about the same no. of spores, as germination takes place faster when their no. is greater, under otherwise the same conditions. Media contg amino acids and a sugar cannot be sterilized by heat; notably in an alk. medium the soln. becomes colored and acidity rises, causing the p_H to fall several units. S. WALDBOTT

New apparatus for measuring the speed of penetration of saline solutions in plant protoplasm. R. BOUILLENNE. *Bull. sci. acad. roy. Belg.* [5], 16, 1017–26(1930).—Strips of tissue of *Tradescantia virginica* and *Allium cepa* are fastened by one end in glass dishes and submerged in a soln. A series of these dishes is arranged in a circle on a stand in such a way that they can be moved successively under a camera. As plasmolysis or deplasmolysis occurs the strip of tissue bends, and this can be followed by a series of exposures taken at intervals. An illustration of the app. is given.
J. J. WILLAMAN

Permeability of cells of Tradescantia virginica and Allium cepa. R. BOUILLENNE *Bull. sci. acad. roy. Belg.* [5], 16, 1027–47(1930).—KNO_3, KCl, NaCl, NH_4Cl and the NH_4 salts of formic, acetic, propionic, butyric and valeric acids were used at p_H 7. The first four cause definite plasmolysis of *Tradescantia* leaves at about 0.20 *N*, and of *Allium* at about 0.13 *N*. The salts of the fatty acids behaved irregularly, and the formate was definitely toxic. They penetrate the cells rather rapidly and hence tend to confuse the detn. of plasmolysis. The isotonic concn for *Tradescantia* and *Allium* are: acetate 0.34 *N* and 0.30 to 0.19 *N*; butyrate, 0.47 for both; valerianate, 0.50 and 0.30 *N*. Cells of *Tradescantia* were plasmolyzed with 0.67 *N* KNO_3, and the rate of deplasmolysis was measured in 0.67 *N* solns. of the NH_4 salts of the fatty acids. The results in min. were: formate, 21; acetate, 6.5; propionate, 5.5; butyrate, 3.5; valerionate, 1.5. Cells of *Allium* may be plasmolyzed and deplasmolyzed 6 times, with an increasing rate of penetration, and then they become useless for the detn. Older leaves are deplasmolyzed more slowly than younger, and the tips more slowly than the middle. J. J. WILLAMAN

Sexuality and cellular oxidation in Mercurialis annua. R. BOUILLENNE AND M. BOUILLENNE. *Bull. sci. acad. roy. Belg.* 16, 1047–51(1930).—Male individuals had a

higher rate of respiration than the females, although the respiratory quotient was the same. J. J. WILLAMAN

The toxic agent of Ambrosia pollen. M. BOUILLENNE AND R. BOUILLENNE. *Bull. sci. acad. roy. Belg.* [5], **16**, 1052–73(1930).—Ragweed pollen (*Ambrosia trifida* and *A. artemisiaefolia*) was extd. with a soln. contg. 0.363 g. KH_2PO_4, 1.431 g. Na_2HPO_4.-$12H_2O$, 5 g. NaCl and 4 cc. PhOH per liter. Exts. as low as 0.01% gave a positive skin reaction. The exts. could be boiled for 1 minute or heated at 75° for 15 hrs. without losing all their activity. A bibliography of 138 titles is given. J. J. WILLAMAN

Detection of F in plants (RECKENDORFER) **7.** A mannan from the bulb of *Lilium* (TAKAHASHI) **10.** Isolation of phytosterolin from wheat embryo (NAKAMURA, ICHIBA) **10.** Blossom xanthophylls. The pigment of the sunflower (ZECHMEISTER, TUZSON) **10.**

Isolation of the antineuritic vitamin. N. STECHOW AND L. WAMOSCHER. *Arch. Pharm. Inst. Univ. Berlin* **13**, 145–7(1927).—In expts. with rice bran, pptn. with K Bi iodide, but not that with $Pb(AcO)_2$, afforded active prepns. B. C. A.

The vitamins of milk and their behavior toward chemical, thermal and physical agents. A. FARINE. *Tech. Ind. Schweiz. Chem.-Ztg.* **1930**, 133–6, 149–50.—The amts. of vitamins A, B and C in milk and milk products are increased when green food is added to the diet. Vitamin C is most easily destroyed, being most sensitive especially to heat. The amt. of D can be increased by irradiation with ultra-violet rays. No appreciable amt. of vitamin E occurs in milk. H. J. DEUEL, JR

Effects of radiant energy on hemorrhagic anemia. HENRY LAURENS AND H. S. MAYERSON. *J. Nutrition* **3**, 465-77(1931); cf. *C. A.* **23**, 2195.—Anemia was produced in 24 dogs by the method and diet of Whipple and Robscheit-Robbins (*C. A.* **19**, 2692). C- and Hg-arc irradiation of these animals results in marked and persistent increases in the no. of erythrocytes and reticulocytes, the responses being more marked with massive exposures than with smaller exposures repeated more often. There was no significant effect on the amt. of hemoglobin formed. When irradiated dogs were fed peaches, apricots or lettuce, immediate hemoglobin increase was noted. C. R. F.

Vitamin studies. XVIII. Biological assay of food materials for vitamin A as influenced by yeast from various sources. HANNAH E. HONEYWELL, R. ADAMS DUTCHER AND JACOB O. ELY. *J. Nutrition* **3**, 491–8(1931); cf. *C. A.* **24**, 2163.—Long-continued expts. on the use of yeast in the ration of albino rats led to the conclusions: Yeast made by the same manufacturer may or may not contain traces of vitamin A. Vitamin A response, the curative method being used, varies depending upon the yeast used as a source of the vitamin B complex. Quant. results in assaying foods for vitamin A will likewise vary, depending upon the potency of the vitamin B complex in the yeast employed. In the interest of accuracy, periodical tests should be made of new yeast supplies in order to prevent this variable from affecting the usual vitamin A technic. Vitamin A may consist of 2 factors, 1 possessing antiophthalmic properties and which tends to preserve normality of other epithelial tissues, and the other factor possessing the growth-stimulating properties usually ascribed to vitamin A. Differences in anti-ophthalmic properties of different lots of yeast probably account for the incidence of ophthalmic symptoms in but 20% of the rats being used for the vitamin A assay. C. R. FELLERS

Metabolic rate and respiratory quotients of rats following the ingestion of dextrin and during fasting. LAURENCE G. WESSON. *J. Nutrition* **3**, 503–18(1931).—By maintaining male rats for some days at the environment under which the respiratory gas exchange is to be detd., the low basal rate of 718 Cal. per sq. m. per 24 hrs. was obtained. This basal value was reached in the 14th hr. after feeding dextrin and was maintained approx. const. for 30 hrs. following. The hourly averages of the respiratory quotients after a dextrin feeding decrease rapidly to 0.744 at the 16th hr. thereafter and slowly with several slight diurnal changes to 0.738 at the 43rd hr. The av.

respiratory quotient for the 38th to 44th hr., inclusive, is 0.733, uncorrected, or 0.722 if corrected for protein metabolism. The gas-exchange studies were definitely controlled and can be reproduced. C. R. FELLERS

Specific dynamic action. GRAHAM LUSK. *J. Nutrition* **3**, 519–30(1931).—A review. L. believes that sp. dynamic action of carbohydrate is due to heat production of the intermediary metabolism rather than to carbohydrate plethora. His views are now in agreement with those of Rubner. C. R. FELLERS

Investigations in the feeding of cottonseed meal to cattle. J. O. HALVERSON AND F. W. SHERWOOD. North Carolina Agr. Expt. Sta., *Tech. Bull.* **39**, 5–158(1930).—Eight years' results are reported in full. The feeding of large amts. of cottonseed meal and hulls to cattle over considerable periods of time results in what is commonly called "cottonseed meal poisoning," a condition formerly ascribed to a toxic substance, *gossypol*. Numerous expts. showed definitely that the disease was not due to a poisonous principle but rather to nutritive deficiencies of the rations. A crit. study of the various combinations of nutritive adjuvants used indicates that cottonseed meal and cottonseed hulls do not contain sufficient Ca or vitamins A, D or B to meet fully the needs of the animals. Great care must be used to select rations furnishing adequate amts. of minerals and vitamins for dairy cows. White corn is likely to be deficient in Ca, P and vitamin A, and corn silage or grain should not be used to supplement cottonseed feeds. The typical symptoms of cottonseed poisoning, *i. e.*, staggers, impaired vision and spasms, were readily reproduced on heifers receiving meals other than cottonseed such as linseed, peanut and soy bean in the presence of minerals. On autopsy, the livers of the animals were shown to be almost totally lacking in vitamin A. Cod-liver oil added to the ration proved moderately efficacious in preventing or curing the condition. Reproduction of cows fed on a cottonseed or similar deficient ration was decidedly subnormal. Numerous expts. where cottonseed meal was supplemented by poor roughage, wheat straw and a small quantity of green feed showed inadequate maintenance, poor reproduction and other conditions attributable to Ca and vitamin-A deficiency. Similarly, rations of cottonseed meal contg. minerals, timothy hay and corn silage did not quite maintain health and vigor in the animals. Even when 1/4 of the entire ration was alfalfa hay and beet pulp was fed in addn., the ration was inadequate for dairy cows over an extended period of time. Cottonseed or other meals from high oil-bearing seeds must be freely supplemented with good hay and possibly non-maize grains to avoid various nutritive deficiencies. Bibliography. C. R. FELLERS

Corn silage versus a mixture of wet beet pulp and molasses for milk production. C. F. MONROE, C. C. HAYDEN AND A. E. PERKINS. Ohio Agr. Expt. Sta., *Bimonthly Bull.* **148**, 3–8(Jan.–Feb., 1931).—Slightly higher milk and butterfat production were obtained on the beet pulp-molasses ration, though insufficient to justify the increased cost of the ration. C. R. FELLERS

Does the feeding of corn silage to dairy cows lead to acidosis? A. E. PERKINS, C. C. HAYDEN AND C. F. MONROE. Ohio Agr. Expt., *Bimonthly Bull.* **148**, 8–11(Jan.–Feb., 1931).—The total acidity of corn silage averaged 2–3%, consisting of lactic and acetic acids. The blood and urine of cattle normally have a slightly alk. reaction. The urine of several cows fed daily rations contg. 30–50 lb. of corn silage as compared with beet pulp showed no significant increase in either total acidity or H-ion concn. NH_3 and bicarbonate CO_2, were also unaffected by the feeding of silage. Conclusion: The org. acids in silage are fully metabolized and do not appear as org. acids or related compds. in the urine. C. R. FELLERS

Relation of food to the growth of pre-school children. MARY A. BROWN. Ohio Agr. Expt. Sta., *Bimonthly Bull.* **149**, 73–6(Mar.–Apr., 1931).—Two groups were formed, based on different economic levels, of 114 kindergarten children. The children were regularly weighed and examd. for phys. defects, etc., for approx. 1 year. Conclusion: It is desirable to include a quart of milk, vegetables, cooked and uncooked fruits, and cereals in the daily diet of the growing child, and eggs should be used several times a week, since a greater rate of growth was observed for those children whose diets contained these foods than for those children whose diets were lacking in quantity in certain food elements. C. R. FELLERS

Adsorption of vitamin A on silica gel. L. L. LACHAT, R. ADAMS DUTCHER AND H. E. HONEYWELL. Penna. Agr. Expt. Sta., *Bull.* **258**, 8(1930) Abstract; *43d Ann. Report of Director.*—Vitamin A in cod-liver oil may be adsorbed on highly activated silica gel so tenaciously that it cannot be rendered available when the silica gel is fed to rats. Toluene removes the adsorbed vitamin A from the silica gel, while acetone exts. are inactive. Further studies on availability before and after adsorption are being continued. C. R. FELLERS

Digestibility by sheep of the constituents of the nitrogen-free extract of feeds. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* **418**, 5-15(1930).—The contents of starch, pentosans, residual N-free ext. and sugars were detd. on 56 feeds. The digestibility by sheep of the sugars, starches, pentosans and residual N-free ext. was detd. by animal feeding tests. Feeds known to be of high feeding value are characterized by a high content of starch, or starch and sugar combined, or if the starch content is not high, by a high content of protein. The N-free ext. of feeds of low feeding value contains a high percentage of pentosans and of residual N-free ext. The N-free ext. of some feeds contains an appreciable percentage of compds. which are not carbohydrates, whose digestibility is uniformly high. For several feeds the digestibility of pentosans was 50–60%, but was somewhat variable. The pentosans in crude fiber are usually digested to a less extent than the total pentosans, or the pentosans in the N-free ext. The residual N-free ext. in hays and fodders is generally digested to a greater extent than are the pentosans. C. R. FELLERS

The nature of dietary deficiencies of milk. J. ERNESTINE BECKER AND E. V. MCCOLLUM. *Am. J. Hyg.* **12**, 503-10(1930).—Of 38 diets in which milk powder was used at 60-85% levels in combination with other substances, only 24 sufficed for the production of young rats. The best supplements from the standpoint of reproduction records were cooked dried beef liver, yeast and a mixt. of ferric citrate and copper sulfate. The liver is believed to owe its value to the Cu and Fe which it contains. S. B. FOSTER

Effect of cod-liver oil on calcium metabolism of young chicks. ARTHUR D. HOLMES AND MADELEINE G. PIGOTT. *Ind. Eng. Chem.* **23**, 190-6(1931).—Four hundred vigorous, day-old Rhode Island Red chicks were divided into 12 comparable pens, and the effect of cod-liver oil on their Ca utilization was detd. (1) when the Ca was obtained from different sources, (2) when it was fed at different levels, and (3) when it was fed at varying ratios to P. Judged by the rate of growth and bone development, the chicks which received cod-liver oil showed better Ca utilization than the controls. The oil was most effective when the Ca-P ratio was low. When this ratio was 5–1 the growth and Ca utilization of both exptl. and control groups were unsatisfactory. S. B. FOSTER

Radiographic study of the effect of irradiated ergosterol on the healing of experimental fractures. J. MORELLE. *Rev. Belge. Sci.* **2**, 226-8(1930); *Bull. Hyg.* **6**, 88 (1931).—M. studied the action of vitamin D on the lesions of the fibula of rats. The rats were divided into 3 groups which were given 0.001 mg., 0.01 mg. and 2–4 mg. of ergosterol per day. Up to the 20th day no results were visible, but after that time in those receiving the medium dose the fracture lines were invisible, while in the controls they were still apparent. After the 30th day there was a dense callus in treated animals while in the controls the disappearance had just begun. Heavy doses caused abnormally dense and exuberant callus formation. GEORGE R. GREENBANK

The mode of action of the vitamin B complex. I. EMIL ABDERHALDEN. *Arch. ges. Physiol.* (Pflügers) **226**, 723-37(1931).—The paralytic symptoms of pigeons fed on a diet of polished rice could be abolished by feeding small quantities of various organ exts. (particularly liver). The bearing of these expts. on the problem of the nature of the vitamin B complex is discussed. **II.** EMIL ABDERHALDEN AND V. VLASSOPOULOS. *Ibid* 808-15.—The *dehydrase* content of liver, muscle, and brain tissue of pigeons maintained on a diet of polished rice is abnormally low. The addn. of yeast or of dried organ exts. to the diet of such pigeons restores the above-mentioned organs to their normal dehydrase content. ARTHUR GROLLMAN

The utilization of soy-bean flour and a new soy protein preparation by man and the lower animals. J. KAPFHAMMER AND H. HABS. *Deut. med. Wochschr.* **56**, 1168-70 (1930). Metabolism expts. on men and dogs showed the value of soy-bean flour as a source of protein in the diet. *Novo-Tropon*, a com. prepn. contg. soy-bean flour, also proved efficacious as a source of protein. ARTHUR GROLLMAN

Carotene and vitamin A. L. K. WOLFF, J. OVERHOFF AND M. VAN ECKELEN. *Deut. med. Wochschr.* **56**, 1428-9(1930).—Carotene and vitamin A were sepd. from a no. of plant and animal substances. Their detn. in such substances is described. ARTHUR GROLLMAN

The effect of hypophyseal extracts and various protein bodies on the specific dynamic action of protein. ERNST HERZFELD. *Deut. med. Wochschr.* **56**, 1558-60 (1930).—Muscle, milk, and liver protein showed a specific dynamic action in normal individuals. ARTHUR GROLLMAN

"Diet 4" for breeding rats for work on vitamin A. SKULI V. GUDJÓNSSON. *Biochem. J.* **24**, 1591-4(1930).—The diet contains (in per cent) skimmed-milk powder

(made from pasteurized milk) 30, rice flour 40, autolyzed yeast 15, hardened coconut oil and shark-liver oil 15. BENJAMIN HARROW

Influence of foodstuffs on the acid-base balance of cattle urine. FREDERICK J. WARTH AND NARAYANA K. AYYAR. *Biochem. J.* **24**, 1595–1600(1930).—Urines from green fodders and cereal straws were alike in contg. excess of alkali and large amounts of CO_2. Urines from over-ripe hays contained very little CO_2 and were neutral or acid. These urines contain very little H_3PO_4 but relatively large amounts of hippuric acid. BENJAMIN HARROW

Studies in embryonic mortality in the chick. I. The effect of diet upon the nitrogen, amino nitrogen, tyrosine, tryptophan, cystine and iron content of the proteins and on the total copper of the hen egg. WM. D. MCFARLANE, HUGH L. FULMER AND THOMAS H. JUKES. *Biochem. J.* **24**, 1611–31(1930).—The source of protein in the diet of the hen has a marked influence on the mortality of the embryos during incubation. As regards total N, total amino N, tyrosine, tryptophan and cystine content, no difference was found in the compn. of eggs of poor hatchability and those of high hatchability. The Cu content varied considerably. The results offer no explanations of the differences in the hatchability of the eggs. BENJAMIN HARROW

Vitamin B deficiency in the rat. Bradycardia as a distinctive feature. ALAN N DRURY, LESLIE J. HARRIS AND CECIL MAUDSLEY. *Biochem. J.* **24**, 1632–49(1930). Vitamin-B deficiency reduces the heart rate from 500–550 per min. to 350–300 per min. BENJAMIN HARROW

Further observations upon the correlation between the arginine and vitamin B content of diets, and the effect of thyroxine upon tumor growth. ESMÉ GILROY. *Biochem. J.* **24**, 1659–65(1930); cf. *C. A.* **24**, 5061.—On a diet deficient in arginine, tumor growth in mice was inhibited in a way similar to a vitamin-B-deficient diet. Injection of thyroxine caused a slight inhibitory effect upon tumor growth. B. H.

Antiscorbutic fraction of lemon juice. IX. SYLVESTER S. ZILVA. *Biochem. J.* **24**, 1687–98(1930); cf. *C. A.* **24**, 2165.—The activity of the vitamin is controlled by the presence of a reducing substance which in itself is not antiscorbutically active. Attempts to replace the reducing substance after mild oxidation have so far failed to activate antiscorbutic fractions which have lost their potency through the destruction of the former. The reducing substance acts perhaps irreversibly as a protective agent against the oxidation of the vitamin. BENJAMIN HARROW

Effect of cooking on the digestibility of meat. WINIFRED MARY CLIFFORD. *Biochem. J.* **24**, 1728–33(1930).—Meats in the raw and cooked condition were digested either with pepsin and trypsin or with trypsin alone, and the rate of hydrolysis was detd. by Sorensen's method. If the rapidity of hydrolysis is taken as a criterion, meat when raw is in the least digestible condition. The most rapidly digested meat is that which is roasted or grilled until it is just red inside with a moist surface when cut. The rate of digestion is the same whether trypsin alone is used or pepsin followed by trypsin. BENJAMIN HARROW

Histopathology of experimental molar caries in rats. HENRY KLEIN AND DAVID H. SHELLING. *J. Dental Research* **11**, 151–7(1931).—"In the course of an investigation on the effects of unbalanced diets on the teeth of rats, it became apparent that frequent caries-like lesions were present in the molars of rachitic rats which had been fed viosterol therapeutically for long periods. The present communication is concerned with a description of the histology of such cavities." JOSEPH S. HEPBURN

Remark on the note of R. C. Gibbs, J. R. Johnson and C. V. Shapiro: The **absorption spectrum of blood and its relation to rickets.** R. SUHRMANN AND W. KOLLATH *Naturwissenschaften* **19**, 65–6(1931).—The neg. results obtained by G., J. and S. (*C. A.* **24**, 5771) on a relation between rickets and the absorption spectrum of blood are attributed to their studying a type of exptl. rickets in rats different from that observed by S. and K.; the authors used different rickets-producing and breeding diets. It is suggested that the absorption method apparently permits of distinction between types of rickets, valuable at least for theoretical work. Standardization of the animals is a prime requisite. B. J. C. VAN DER HOEVEN

Physiological significance of some inorganic elements. E. V. MCCOLLUM AND ELSA ORENT. *J. Maryland Acad. Sci.* **2**, 33–6(1931).—A diet adequate with respect to vitamins, proteins and salts, but which is spectroscopically free from Mn, has been prepd. Rats which were maintained upon this diet grew normally for about 8 months. However, second litters could not be obtained, apparently because the testes had degenerated. The females bore young which survived but a few days, seemingly because sufficient milk for their maintenance was not secreted. Mn is therefore an indispensable nutrient element for mammals. W. D. LANGLEY

Simple methods for metabolic balance studies and their interpretation. EVA DONELSON, BETTY NIMS, HELEN A. HUNSCHER, CARROLL F. SHUKERS AND ICIE G. MACY. *J. Home Econ.* 23, 267–72(1931).—The mean difference between the chem. compn. of a diet as computed from standard tables and as detd. in the lab. was 2–5%. N varied 0.7–38%; Ca varied 0–22%; and P varied 0–38%. The magnitude of retention or loss that can be considered significant in any expt. is detd. by calcg. the av. deviation. A calcn. of metabolic balance for short observation periods shows daily fluctuations, while balances for longer periods show the general tendency better. A list of 23 references is given.
AMY LEVESCONTE

The effect of feeding sorghum and sugar-cane sirups on nutritional anemia. OLIVE SHEETS AND ERNESTINE FRAZIER. *J. Home Econ.* 23, 273–80(1931).—Sorghum and sugar-cane sirup are effective in producing hemoglobin in the rat. A few expts. with Crooked Top sirup proved it to be almost as potent as calf liver.
A. LEV.

A differentiation of the so-called antipellagric factor, vitamin G. BARNETT SURE, MARGARET ELIZABETH SMITH AND M. C. KIK. *Science* 73, 242–3(1931).—Many expts. indicate that vitamin G contains 2 factors, one producing dermatitis without affecting the growth of rats, the other stunting the growth without sign of skin lesions. It is suggested that the growth-promoting factor be designated by the letter F.
AMY LEVESCONTE

Comparison between irradiation of diet and supplemental irradiation of animals in vitamin A and D deficiency. F. E. CHIDESTER, A. G. EATON AND N. K. SPEICHER. *Science* 73, 190–1(1931).—Rats depleted of vitamins A and D were fed on a diet (Sherman No. 380) low in D and deficient in A and given 0.01 mg. of ergosterol daily. Some of these rats were irradiated also for 30 sec. daily. The addnl. irradiation stimulated growth for a short time but did not produce the striking effects observed when FeI, was also added.
I. M. LEVINE

Sterol content and antirachitic activatibility of mold mycelia. L. M. PREUSS, W. H. PETERSON, H. STEENBOCK AND E. B FRED. *J. Biol. Chem.* 90, 369–84(1931).—The autoclaved, dried and finely grown pads, resulting from the growth of certain molds in a synthetic, inorg. medium contg. 4% glucose as the source of C, were irradiated with ultra-violet light and fed to rachitic rats. Five kinds of mushroom were also tested for antirachitic activatibility. Eight of 12 molds and 3 of the mushrooms brought about distinct healing of rickets even when fed at a level of 10 mg. of irradiated material per rat for 7 days. The total alc.-sol. sterol, detd. by the digitonide method, in 11 molds and 4 mushrooms varied from about 0.1 to 1.0% of the dry wt. of the fungus material. In most cases 90% or more of the alc.-sol. sterol was present in the free state. The sterol content of the molds varied not only with the species but also with different strains of the same species and was decreased by increasing the glucose content of the medium. Supplementing the medium with such org. nutrients as an aq. ext. of malt sprouts or fresh yeast did not appreciably change the sterol content but the mycelial growth of 1 of the strains studied, *Aspergillus oryzae*, was increased from 20 to 50%. A decrease of 56% in the wt. of the pad resulted from increasing the incubation period of this strain from 10 to 50 days. In most cases increasing the glucose content of the medium to 10 or 20% more than doubled the wt. of the dry pad. Bibliography of 22 references.
A. P. LOTHROP

The induction of tetany in rachitic rats by means of a normal diet. ALFRED F. HESS, MILDRED WEINSTOCK, H. R. BENJAMIN AND J. GROSS. *J. Biol. Chem.* 90, 737–46(1931).—"Tetany can be induced in rachitic rats simply by an abrupt change from a rickets-producing ration, high in Ca and low in P, to a normal ration of dried milk or of dried milk and whole wheat. The fall in Ca in the serum which is brought about by this means develops within 48 hrs. but is maintained for only a few days. This striking reaction is due not to an absolute or to a relative increase of P in the dietary but to a sudden shift in the Ca:P ratio in the subsequent diet as compared to the preliminary diet. When this ratio of Ca:P is decreased from about 4:1 to 1 or 1.5:1 tetany ensues, whereas if it is decreased only to about 2:1 the fall in Ca and nervous symptoms do not come about. Attention should be directed to the effect of marked alterations in the constitution of dietaries, as such shifts may help to explain nutritional disturbances which are inexplicable merely from the standpoint of adequacy."
A. P. LOTHROP

The effect of heat upon the biological value of cereal proteins and casein. AGNES F. MORGAN WITH THE COÖPERATION OF FLORENCE B. KING, RUTH E. BOYDEN AND V. ANN PETRO. *J. Biol. Chem.* 90, 771–92(1931).—The digestibility of proteins toasted at 150–200° for 30–45 min. is but little different from that of the raw protein but there are differences in the biol. values (ranging from 10 to 19%) which are in all cases more

than 6 times as great as their probable errors. The unexplainable loss of N occurs chiefly in the urine, indicating that the change produced by the heat treatment lies probably in the assortment or availability of the amino acids absorbed. The addn. of 5% casein to the toasted diets very nearly made up the discrepancy between the latter and correspondingly supplemented raw diets, thus indicating that the deficiency observed lay in the protein fraction of the toasted diet. With wheat gluten the max. growth rate (1.4 g. per g. of protein eaten in 56 days) occurred when the diet contained 18% of the protein. At an approx. 12% level the biol. values of raw and toasted gluten were 66 and 54, resp. The values for raw and toasted casein at an 8% level were 66 and 53. Cooking with H_2O, in general, slightly increased the biol. value of the protein. The values of raw, water-cooked and toasted whole-wheat protein alone and supplemented with 5% casein were found to be 64, 67 and 52 for wheat alone and 67, 75 and 69 with wheat plus casein. Bibliography of 33 references. A. P. L.

Digestive erythropenia and factors which cause it. GIUSEPPE SOLARINO AND VITTORIO CATTAINO. *Boll. soc. ital. biol. sper.* **5**, 985–9(1930).—The administration of a diet rich in protein substances (meat) or in HCl in concn. corresponding with that of gastric juice causes in normal dogs and in man a marked, const. erythropenia. Erythropenia more marked and of longer duration follows the administration of liver. Digestive erythropenia is related to 2 series of factors: to the accumulation of blood in the splanchnic area and to the erythrocytic activity of certain hemopoietic tissues. PETER MASUCCI

Studies on the metabolism of fats. VII. The glycogen content of adipose tissue of rats under varying conditions of alimentation. G. SCOZ. *Boll. soc. ital. biol. sper.* **5**, 1037(1930); cf. *C. A.* **24**, 5804.—Glycogen detns. expressed as mg. per 100 g. adipose tissue were: fasting animal 181, animal at const. wt. 527, animal after refeeding 1600. PETER MASUCCI

The diet in diabetes of children. PEDRO B. LANDABURE AND FÉLIX PUCHEU. *Semana méd.* (Buenos Aires) **1931**, I, 360–3.—The caloric intake should be in the first decade of life 69 cal. per kg. wt., in the second 48 cal. The requirement for carbohydrates is 2.09 g. per kg. in the first decade and 1.44 g. in the second decade; for proteins it is 2.47 and 1.58 g., resp., and for fats 5.57 and 3.87 g. Only in a few cases is it possible to dispense with insulin. A. E. MEYER

Calcium metabolism. ALBERT RANSON. *Semana méd.* (Buenos Aires) **1931**, I, 465–7.—After a short review on the subject, opocalcium is recommended, a product composed of minerals, parathyroid, suprarenal and thymus gland, which has been exposed to ultra-violet light. A. E. MEYER

Results of exclusively dietary treatment in forty-six cases of obesity. EGGERT MØLLER. *Acta med. scand.* **74**, 341–52(1931).—Forty-six patients were treated with a diet contg. 950 calories with about 6 g. protein N per day. This treatment continued for 54 days, the av. loss in wt. sustained being 8.8 kg. The basal metabolic rate of one patient who lost 29 kg. in 5 months showed no significant changes during that period. S. MORGULIS

Influence of some fats and oils, meat and bread on growing rats. V. A. LEIBOVICH-LIVSHINA. *Biochem. Z.* **231**, 260–73(1931).—Large amts. of cod-liver oil cause toxic effects which manifest themselves in extensive losses of body wt., trophic disturbances and premature death. With corresponding quantities of olive oil the body losses are smaller and the animals do not die prematurely even in long-continued expts. Small or moderate amts. of olive, linolic and other oils do not stimulate the growth of the rat. The greatest stimulating effect upon increase in body wt., especially following a preliminary fast, has been obtained with 5 g. meat added to a bread diet or with meat alone. The stimulating effect of the meat lasts longer in growing rats which have had a previous fasting experience than in rats without this. S. MORGULIS

The presence of vitasterol A in the cacao and its products of extraction. H. LABBE, HEIM DE BALSAC AND R. LERAT. *Bull. soc. therap.* No. **10**, 12 pp.(1930); cf. *C. A.* **25**, 729.—The following exts. of the cacao bean were made: (1) cacao butter; (2) alc. ext. of bean; (3) alc. ext. of shell; (4) the tailings of crystn. after extn. of α- and β-sterols. These products, in comparison with cod-liver oil, were tested by the color reaction with $AsCl_3$ and $SbCl_3$ according to the procedure of Carr and Price. The alc. ext. of the bean gives a feeble color reaction with both reagents, $AsCl_3$ and $SbCl_3$; the alc. ext. of the shell and the tailings of crystn. give color reactions comparable to that obtained with cod-liver oil. These exts. were further tested for their growth-promoting and antirachitic properties in expts. with white rats which had been sensitized by a vitamin-A-deficient diet according to a procedure of Lecoq. It was shown that important amts. of a vitasterol, similar to vitamin A of growth and develop-

ment, were present in the alc. ext. of cacao shell and in the tailings of crystn. and a small quantity in the alc. ext. of the bean. In the same order of importance, small quantities of antixerophthalmic vitamin were shown to be present in the exts.
N. M. NAYLOR

Fat-soluble vitamins in tumor tissues. MIDZUHO SUMI AND WARO NAKAHARA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, No. 283, 69–74(1931).—The expt. was undertaken to det. the vitamin A and D contents of tumors. Tumors were obtained as follows: Rous chicken sarcoma, Fujinawa rat sarcoma, Flexner-Jobling rat carcinoma and Bashford mouse carcinoma. Tumors were removed at 3 weeks' growth, dehydrated and dried. The fats were obtained from them by extn. with ether and then alc. Fat consts. were detd. The total cholesterol content is high: chicken sarcoma 16%, rat carcinoma 13%, rat sarcoma 12%, mouse carcinoma 12%. The absorption spectra of the cholesterol from chicken and rat sarcoma showed absorption bands for ergosterol. These tumor exts. were tested for vitamin A by being fed to white rats on Steenbocks' rickets-producing diet, namely wheat gluten 20, yellow cornmeal 76, $CaCO_3$ 3 and NaCl 1%. After 30 days on this diet, the ration was supplemented by 1 to 2 drops of the tumor oil per rat per day. It was shown that these tumor oils tended to heal rachitic lesions indicating the presence of vitamin D. Color reactions with H_2SO_4, with acid clay, and with $SbCl_3$, as used for vitamin A, with each tumor oil gave neg. results indicating the absence of vitamin A.
N. M. NAYLOR

Fixation of strontium in experimental rickets. G. MOURIQUAND, A. LEULIER AND NOGIER. *Compt. rend. soc. biol.* **106**, 18–9(1931).—Sr is not found in the normal boney tissue of rats, and is fixed only irregularly and in infinitesimal traces in this tissue when young rats are fed a diet contg. 2.2% $SrCO_3$. However, the wt. of the epiphysis ash of young rats fed on this diet is always notably greater than that of young rats fed on a Sr-free diet.
ALBERT L. RAWLINS

Investigation on a colorimetric method for estimating the silverskin (antiberiberi-vitamin) percentage of rice. J. P. SPRUIJT. *Chem. Weekblad* **27**, 298–304(1930). See *C. A.* **24**, 5802.
W. GORDON ROSE

Quantitative relations of the dry matter of the food consumed, the heat production, the gaseous outgo and the insensible loss in body weight of cattle. MAX KRISS. *J. Agr. Research* **40**, 283–95(1930).—A biometric study of relations between values representing the feed consumption, the production of heat, CO_2, water vapor and CH_4 and the insensible loss in body wt. of cattle showed that for practical purposes the dry matter of feed consumed is a better basis for predicting the heat production of cattle than the insensible loss in body wt.
W. H. ROSS

The irradiation of ergosterol. G. RANZOLI. *Boll. chim. farm.* **69**, 803–7(1930).—After discussing the phenomena involved in vitamin D deficiency and the chem. and therapeutic properties of irradiated ergosterol, R. stresses the importance of the exact standardization of the latter. On account of the conflicting statements in the literature he is not convinced that the spectrographic changes exhibited by ergosterol after irradiation are indicators of its activity. He does not attach practical significance to Black's findings that irradiated ergosterol has a lower m. p. than the non-irradiated substance, because the difference between the m. ps. of the 2 sterols is only very slight. R. believes that the biological methods are difficult to carry out in the chem. lab. After studying the reaction of Shear and Kramer R. convinced himself that this reaction is a feasible method for the approx. estn. of the quantity of ergosterol that by irradiation had been converted into the active principle.
G. SCHWOCH

Proteins and alimentation. GIOVANNI ISSOGLIO. *Giorn. farm. chim.* **80**, 58–62 (1931).—A review.
G. SCHWOCH

Electrolytic dissociation and serum protein content of the blood of nurslings with nutritional disturbances. B. VASILE. *Pediatria Rivista* **38**, 1217–26(1930).—Blood samples were taken 4 hrs. after the meal, from 5 healthy nurslings, 6 nurslings with acute nutritional disturbances, and 13 nurslings with chronic nutritional disturbances. The protein content of the serum was within the normal range in most of the chronic cases, while it was augmented in the acute cases. The electrolytic dissocn. was more or less normal in the serum of the chronic cases and was diminished in the acute cases. Numerous references are given.
G. SCHWOCH

The effect of altered acid-base equilibrium on growth. L. ZILZER. *Magyar Orvosi Archivum* **31**, 171–6(1930).—Rats about 25 days old, about 30 g. in wt. and from the same litter were fed acid and basic diets. The compn. of the diet was: albumin, fats, carbohydrates and some neutral salts, to which were added the acid and basic salts, resp. Nine groups were examd. In every group there were 3 acid- and 3 base fed animals. Increase in wt. was observed during 5–13 weeks. In 2 groups

the acid-fed animals increased in wt.; in the other groups the base-fed animals gained. The av. gain of 27 base-fed animals was 8% greater than the av. of 27 acid-fed animals. Diuresis caused in both acid- and base-fed animals the same loss of body wt. which shows that the difference in growth was not caused by the retention of fixed fluid. H. TAUBER

The significance of the calcium and phosphorus content of the food. K. WALTNER. *Magyar Orvosi Archivum* 31, 276–82(1930).—For white rats the min. quantity of P necessary for optimum growth is the same as that of Ca. A food contg. P and Ca in the same ratio as that in human milk is deficient in P for rats. Twice the min. amt of one of the elements can be ingested without injury in the presence of the min. amt of the other. Ca deficiency of the food can be partly compensated by vitamin D, but the deficiency in P only to a very limited degree. H. TAUBER

The influence of liver diet on the action of hemolytic poisons. V. FEHÉR. *Magyar Orvosi Archivum* 31, 446–50(1930).—The development of anemia in rats caused by phenylhydrazine poisoning is retarded by liver diet, but the regeneration of blood is not stimulated. Typical anemia cannot be produced by Cu acetate. Liver diet has no effect upon Cu acetate poisoning. H. TAUBER

The destructive action of finely divided solids on vitamin A. JOSEPH K MARCUS. *J. Biol. Chem.* 90, 507–13(1931).—The activity of vitamin A concentrates from cod-liver oil (Marcus, *C. A.* 23, 1162, 4093) is largely destroyed on standing 8–26 days in presence of various finely divided powders, whether in air or CO_2. K. V. T.

The fundamental food requirements for the growth of the rat. VI. The influence of the food consumption and the efficiency quotient of the animal. LEROY S. PALMER AND CORNELIA KENNEDY. *J. Biol. Chem.* 90, 545–64(1931); cf. *C. A.* 23, 4499.—The digestibility of various stock diets by rats varies from 80 to 95%, and diets should therefore be compared on the basis of an equal intake of digestible dry matter. This is done very reproducibly by collecting, drying and weighing the feces. When diets are thus compared, differences in the growth curves on synthetic vitamin-contg. and natural complete diets almost disappear, though the natural diet appears still slightly superior. Furthermore, the efficiency of food utilization, expressed as the efficiency quotient (E. Q.), or gain in wt. per 100 g. body wt. per g. of food digested, is higher in males than in females. The greater gain in wt. of males is due to this (cf. Osborne and Mendel, *C. A.* 20, 3487, Mendel and Cannon, *C. A.* 22, 798). Differences in E. Q. also account for the variations in growth between groups of rats on the same diet. The stimulating effects of fresh lettuce, liver and carrots, given with yeast, on the growth of rats are shown to be due solely to effects on the food consumption, when allowance is made for differences in the E. Q. With the same method yeast and wheat embryo are found equally effective as sources of water-sol. vitamin in a diet otherwise complete. By means of the E. Q., growth expts. can be more accurately controlled, and individual variation in gain in wt. of animals can be partially eliminated. K. V. T.

A critique of the line test for vitamin D. CHARLES E. BILLS, EDNA M. HONEYWELL, ALICE M. WIRICK AND MILDRED NUSSMEIER. *J. Biol. Chem.* 90, 619–36(1931).—The 4 grades or degrees of healing of rickets devised by Bills and McDonald (*C. A.* 20, 2522) are not proportional to the dosage of vitamin D. A graphic method is described whereby the amt. of diln. required for any vitamin-D-contg. prepn. to give 2+ healing can be detd. Av. cod-liver oil is taken as that which induces 2+ healing when given to rickety rats at 1/4% in diet 3143 for 5 days. The sex, color and wt of rats are not of importance in the line test. The relation of dosage required to the duration of the test period (between 3 and 14 days) is plotted, and the probable error of the method estd. K. V. THIMANN

E. K. MARSHALL, JR.

Basal metabolic rate of medical students and nurses in training at Charleston, S. C. ROB E. REMINGTON AND F. BARTOW CULP. *Arch. Internal Med.* 47, 366–75(1931).—The basal metabolic rate of student nurses and male medical students at Charleston, S. C., showed results 10% lower than the Aub-Dubois standards. The I intake, dietary

habits and the state of nutrition are not believed to be responsible for the results obtained. J. B. BROWN

Effect of acidosis upon capacity for work. H. DENNIG, J. H. TALBOTT, H. T. EDWARDS AND D. B. DILL. *J. Clin. Investigation* 9, 601–13(1931); cf. *C. A.* 24, 2504.—Acidosis produced by the oral ingestion of NH_4Cl lowers the capacity for work as evidenced by decrease in capacity for O debt. The buffer value of blood proteins is reduced 1/9 or more with a decrease of 1/2 in CO_2 capacity. The ability to neutralize lactic acid is lowered. These factors are raised in alkalosis. J. B. BROWN

Normal standards of gastric function. W. SCOTT POLLAND AND ARTHUR L. BLOOMFIELD. *J. Clin. Investigation* 9, 651–8(1931).—The results of gastric analysis, detd. under fasting basal conditions and resulting from the injection of histamine, are plotted in a number of charts showing the normal ranges. The charts are useful in clinical diagnosis. J. B. BROWN

Studies on the physiology of the parathyroid glands. II. The relation of the serum calcium to the serum phosphorus at different levels of parathyroid activity. FULLER ALBRIGHT, WALTER BAUER, JESSIE REED COCKRILL AND READ ELLSWORTH. *J. Clin. Investigation* 9, 659–77(1931); cf. *C. A.* 23, 5231.—Study of a large no. of simultaneous detns. of serum Ca and inorg. P in patients with hypo- and hyper-parathyroidism shows a slight reduction of P at high Ca level and a marked increase of P at low Ca level, so that the product of Ca and P is roughly const Parathyroid dysfunction is a disorder in which body fluids show normal Ca phosphate but an abnormal ratio of Ca to phosphate. At high Ca levels, however, P is no longer excreted and the fluids contain high Ca phosphate, with calcification elsewhere than in the bones as the result. The data do not explain the casual relationship between Ca rise and P fall. J. B. BROWN

The effect of injections of female sex hormone (estrin) on conception and pregnancy in the guinea pig. G. LOMBARD KELLY. *Surgery, Gynecol. Obstet.* 52, 713–22 (1931); cf. *C. A.* 24, 3816.—Small doses of estrin injected into female guinea pigs prevent conception. Pregnancy may be interrupted by this hormone. An excess of female sex hormone in the blood over the corpus luteum hormone is incompatible with conception. J. B. BROWN

Hormonal sterilization. K. JUNKMANN. *Z. angew Chem.* 44, 162–3(1931).—A review and bibliography are given of the different chemotherapeutical ways of producing facultative sexual sterility in the animal and human body. During pregnancy the corpus luteum prevents the ripening of new ova by internal secretion. The same effect is obtained by the injection of prepns. from ovaries or placentas of pregnant animals, such as placentaoptone (Merck), progynon, folliculin, menformone or the inner secretions of the corpus luteum. The hormones of the anterior lobe of the pituitary body can have the same effect, though the mechanism of their action is different. In the male body sterility can be produced by administering female sexual hormones. ALFRED BURGER

Combined peptic-tryptic digestion in vitro and the digestibility of foodstuffs. A. RONCATO. *Arch. fisiol.* 28, 69–98(1930).—See *C. A.* 25, 329. E. J. C.

The existence of a pancreas hormone which lowers blood pressure. P. GLEY AND N. KISTHINIOS. *Wiener klin. Wochschr.* 43, 1530–6(1930).—The amt. of the hormone is quite variable in different com. insulin prepns. Its effect is not the same as that of histamine or choline. It neutralizes the effect of adrenaline on blood pressure. D. B. DILL

Action of the heart hormone, "Eutonon," from the liver. H. SALOMON AND G. ZUELZER. *Z. ges. exptl. Med.* 66, 291–324(1929).—The response to eutonon was detd. in the frog heart, various heart-lung prepns and in selected clinical cases. F. L. D.

The antimasculine action of the female sex hormone, menformone. E. BORCHARDT, E. DINGEMANSE, S. E. DEJONGH AND E. LAQUEUR. *Z. ges. exptl. Med.* 68, 86–105(1929). F. L. DUNN

Corpus luteum and the sexual hormone. L. FRAENKEL AND E. FELS. *Z. ges. exptl. Med* 68, 172–84(1929). F. L. DUNN

A hormone affecting heart activity. XIII. Effect on the frog heart. L. HABERLANDT. *Z. ges. exptl. Med.* 68, 185–95(1929); cf. *C. A.* 24, 5817–8; *Med. Klin.* 1929, No 14. The action of Hormocardiol (Hoechst) on the frog heart is discussed. F. L. DUNN

Effect of muscle activity, adrenaline and stimulation with the galvanic and faradic currents upon the blood sugar. M. DORLE. *Z. ges. exptl. Med.* 69, 242–54(1930).—Below the point of fatigue muscle activity produced a variable response in the blood sugar and in various diseases and constitutional types. Adrenaline produced the same reaction in the two constitutional types. Elec. stimulation of the gastro-intestinal canal

in animals produced the greatest rise in blood sugar. The rise in blood sugar did not parallel the rise in blood pressure following the injection of adrenaline. F. L. DUNN

The mercapto group in blood cells. E. GABBE. *Z. ges. exptl. Med.* **69**, 392–421 (1930).—A method is described based on the oxidation of the SH group by $K_4Fe(CN)_6$ in strongly acid soln. by which the relation of SH and SS groups in glutathione and thionine can be detd. in blood. In venous blood the SH form is found, while in arterial or oxygenated blood the proportion of SH group is reduced 10–50%. The SH combination remains attached to protein when the soln. is treated with CCl_3CO_2H, neutralized with U acetate in the cold, but it is sepd. following hemolysis. The SH content of the blood cells increases following bleeding, anoxemia and $PhNHNH_2$ poisoning. There is an extensive bibliography. F. L. DUNN

Metabolism at reduced pressure. I. H. ELIAS AND M. TAUBENHAUS. *Z. ges exptl. Med.* **69**, 529–60(1930). F. L. DUNN

Behavior of δ-keto-*n*-hexoic acid in the perfused liver. WALTER L. DULIÈRE AND HENRY S. RAPER. *Biochem. J.* **24**, 1672–7(1930).—The Na salt of δ-ketohexoic acid on perfusion through the liver yields acetone bodies; this indicates a β-oxidation BENJAMIN HARROW

Male hormone. IV. CASIMIR FUNK AND BENJAMIN HARROW. *Biochem. J.* **24**, 1678–80(1930); cf. *C. A.* **24**, 5824.—A simplified method of prepg. the hormone is described. This involves the extn. of strongly acidified male urine with $CHCl_3$, heating the evapd. $CHCl_3$ residue with alkali, repeatedly extg. the alk. solution with ether, evapg. the ether ext. and taking up the residue with oil. About twice as much of the hormone can be obtained from a strongly acidified urine as from an alk. urine. An important difference in the chem. behavior of the male and female hormones has been noted. BENJAMIN HARROW

The presence of a volatile organic chlorine compound in blood. NOAH MORRIS AND SAMUEL MORRIS. *Biochem. J.* **24**, 1716–22(1930).—For each blood there is a certain max. and min. amt. of volatile Cl present beyond which the content does not pass. The Cl in normal blood probably exists in 3 forms: (*a*) inorg., (*b*) org. non volatile and (*c*) org. volatile. BENJAMIN HARROW

Studies on the biochemistry of sulfur. VIII. Rate of absorption of cystine from the gastro-intestinal tract of the white rat. M. X. SULLIVAN AND W. C. HESS. *U. S. Pub. Health Repts.*, Suppl., No. **89**, 16 pp.(1931); cf. *C. A.* **25**, 2449.—Studies are made on the rate of absorption of cystine, fed as the Na salt, from the gastrointestinal tract of the rat by means of 3 cystine methods, the Folin-Marenzi method, the Okuda iodometric method and the Sullivan method. The last two methods are in close agreement when corrections are made for the cystine value of the Na cystinate fed and the % recovery of cystine in the method of extn. The value found by these methods is, in round nos., 50 mg. of cystine per 100 g. of body wt. per hr.—a value which puts cystine in the same class as other amino acids as far as absorption is concerned. The F.-M. method gives a lower value, in round nos., 30 mg. of cystine per 100 g. of body wt. per hr., in agreement with the work of Wilson (cf. *C. A.* **24**, 3821), with the same method. If the value obtained by the F.-M. method is the true one, this method must be reacting to a desulfurized changed cystine left in the gastro-intestinal tract, a complex to which the other methods do not react. If this assumption is made that the excess of material reacting to the F.-M. method is only changed cystine, then the findings by the F.-M. method are the true rate of absorption of cystine by the white rat. Data are given to show that hydrolyzates of amino acids with no cystine present react pos. as cystine in the F.-M. method, but neg. in the other 2 methods, and that feeding glycine, and especially alanine, gives an increase in cystine value by the F.-M. method. Indications were obtained of an increase in glutathione content of the liver by feeding cystine. There are 27 references. J. A. KENNEDY

Modern conceptions on the antagonism of the sexual glands. ANGELO MIGLIACCA. *Boll. soc. ital. biol. sper.* **5**, 1082–4(1930). PETER MASUCCI

Relation between the calcium in the blood and the inhibitory action of the splanchnic nerve. E. GLEY AND H. JANKOWSKA. *J. physiol. path. gén.* **28**, 789–99(1930). The inhibitory action of the splanchnic nerve on the movement of the intestines depends, as does its vasomotor action, upon the Ca content of the blood. When this content falls $^1/_3$ or $^1/_2$ there results a large diminution and sometimes even a temporary suppression of the inhibitory action. This action is reëstablished rapidly under the influence of Ca injection. The inhibitory system is less sensitive to Ca deprivation than is the vasomotor system. L. A. MAYNARD

Suprarenal capsules and glutathione. A. BLANCHETIÈRE, LÉON BINET AND A. ARNAUDET. *J. physiol. path. gén.* **28**, 816–21(1930).—The suprarenal gland is the organ

which is richest in glutathione. The amt. of glutathione diminishes after ovariotomy and increases considerably during lactation. The venous blood of the suprarenals is particularly rich in glutathione. Perfusing the glands with blood to which glutamic acid and cystine have been added causes an increase of glutathione in the perfusate and in the tissues of the gland, indicating that glutathione can be synthesized from these constituents. L. A. MAYNARD

Psychic influences upon the calcium content of the blood serum. M. CH. EHRSTRÖM. *Acta med. scand.* **74**, 378–95(1931).—The effect of induced sleep is the same as that of normal sleep upon the Ca level of the serum. Psychic functions which are characterized by a state of quiet produce an effect upon the chemistry of the blood which manifests itself in a lowering of the serum Ca, while psychic states characterized by restlessness have the opposite effect upon the serum Ca. S. MORGULIS

The ammonia content and ammonia formation in muscle and its relation to function and change in condition. VIII. The assumed participation of the amide nitrogen of blood and muscle protein in the chemical processes of active muscles. T. MANN. *Biochem. Z.* **231**, 33–8(1931).—This is chiefly a critical examn. of the expts. of Bliss (*C. A.* 23, 1946), who claims for the tissues the ability to synthesize from NH_4 ions and blood protein amide compds. and to utilize these amide groups for the neutralization of acids produced during work. It was found that neither in the human blood nor in the isolated frog muscle does amide N take part in the chemistry or the metabolic processes. **IX. The position of ammonia formation in the series of chemical processes in active muscle.** WL. MOZOLOWSKI, T. MANN AND C. LUTWAK. *Ibid* 290–305.—The curve of NH_3 formation during activity of muscles poisoned with CH_2ICO_2H shows that the largest production of NH_3 takes place not during activity but during fatigue, exhaustion of the creatine-phosphate and the development of rigidity. S. MORGULIS

Experimental studies on the influence of air rarefaction on the resistance of red blood corpuscles to hypotonic salt solutions. CLARA NAEGELI. *Biochem. Z.* **231**, 95–102(1931).—Keeping animals in rarefied air greatly affects the resistance of their red blood cells to hypotonic NaCl solns. and after 6–8 days the min. resistance diminishes by 0.02–0.08% NaCl and the max. increases at least 0.08%. S. MORGULIS

Changes in the physical state of inorganic components of serum under reciprocal influences. HANS G. SCHOLTZ. *Biochem. Z.* **231**, 135–43(1931).—Studies by means of ultrafiltration show that a colloidal Ca-P complex is formed in serum when either the Ca or P level is raised. A similar complex is also formed with Mg. The addn. of $CaCl_2$ to serum increases the ultrafiltrability of the K and the addn. of $MgCl_2$ increases that of Ca. The hypothesis of a colloidal K compound in serum is given support by these expts. S. MORGULIS

Studies on blood glucolysis. III. Inhibition of glucolysis. H. K. BARRENSCHEEN AND KARL BRAUN. *Biochem. Z.* **231**, 144–72(1931); cf. *C. A.* **25**, 1889.—Under all conditions or agents which inhibit glucolysis of the erythrocytes (hemolysis, narcotics such as ether and $CHCl_3$, fluorides, oxalates and the monohalogen derivs. of AcOH, CH_2XCO_2H) there is a splitting of inorg. P from org. combination, the chief source being the pyrophosphate fraction of the org. phosphate. With fluorides and CH_2XCO_2H the inhibition of glucolysis is assocd. with a synthesis of difficultly hydrolyzable esters related to the hexosediphosphate fraction. From these considerations it is concluded that the pyrophosphate fraction is essential for the glucolytic process and is either the coenzyme or the activator of the coenzyme. This is sustained by such facts as the following: the fermentation of yeast prepns. free from, or poor in, coenzyme is somewhat activated by the addn. of the pyrophosphate fraction from erythrocytes, and the inhibition of glucolysis by hemolysis, fluorides or CH_2XCO_2H is accompanied by an accumulation of methylglyoxal from added hexosediphosphate. S. M.

Cholesterols in structural combination in the protoplasm. VI. Studies on the cow spleen. G. PFEIFFER. *Biochem. Z.* **231**, 239–43(1931); cf. *C. A.* **25**, 1889.—The spleen of the 1-yr.-old cow contains 0.0946% total cholesterol per 100 g. fresh substance. Of this 64.4% are cholesterol + oxycholesterol (oxycholesterol = 6%) and 35.6% cholesterol esters. Of the latter the oleic acid of cholesterol was 7.5% and of oxycholesterol 28.0%. The spleen shows thus a higher cholesterol content than other organs which is assocd. with its physiol. function of destroying red blood cells. The cholesterol set free in the process of erythrocyte destruction accumulates in the spleen. S. MORGULIS

Presence of ergosterol in the human brain. IRVINE H. PAGE AND WILH. MENSCHICK. *Biochem. Z.* **231**, 446–59(1931).—The absorption spectra were detd. of the purified sterol fraction from the brains of fetuses, newborn babies, lactating babies and adults. In the first three the absorption maxima of the brain sterols were at 294, 283 and

250 mμ, resp. The absorption at 294 and 283 mμ belongs to ergosterol, and its concn. in the cholesterol diminishes from 0.05% (fetus) to 0.01% in the 1½-yr.-old baby. The substance corresponding to the absorption band at 250 mμ has not yet been identified. The ergosterol has been identified by means of digitonin pptn. and change in absorption spectrum under the influence of ultra-violet radiation. The absolute amt. of ergosterol reaches a max. of 1 mg. in the brain of the 1-yr.-old baby, and then diminishes considerably. S. MORGULIS

The non-inhibition of cell respiration by hydrocyanic acid. OTTO WARBURG *Biochem. Z.* 231, 493–7(1931).—Dixon's discovery (*C. A.* 24, 426) that KCN affects only 60% of the cell respiration is shown to be based on error. Liver, kidney and spleen cells are injured by the phosphate buffer, as used by Dixon. When these cells are experimented with in a Ringer-$NaHCO_3$ + CO_2 medium their respiration is completely inhibited by KCN just as is that of yeast cells. Attention is called to several other exptl. errors in Dixon's work. A no. of instances are cited demonstrating that injury of the cell frequently affects the inhibition of its respiratory activity under certain conditions. W. points out that the cardinal problem in cellular respiration is not whether O_2 or H_2 is activated but whether or not activation is catalyzed by Fe. From the fact that baker's yeast heated 90 min. at 52° practically loses the ability to oxidize physiol substances, though it can still oxidize a mixt. of *p*-$C_6H_4(NH_2)_2$ and α-naphthol to indophenol, which is also inhibited by CO, Keilin (*C. A.* 23, 3719) concluded that the respiratory enzyme is the indophenoloxidase. The reaction with the heated yeast, however, is irregular and the expts. are interpreted as showing merely that the respiratory enzyme has been injured. S. MORGULIS

Skin and climacterium. CLARA NAEGELI AND MARIAN FEILNER. *Endokrinologie* 8, 81–121(1931). —General. S. MORGULIS

The endocrine function of the placenta. ARTHUR V. PROBSTNER. *Endokrinologie* 8, 161–9(1931).—From the fact that a patient who underwent an operation for double ovariectomy during pregnancy completed the term, gave birth to a normal child and still continued to secrete in the urine the sex hormone, just as the normal female does, it is concluded that the hormone must be produced by the placenta. S. MORGULIS

The mechanism of the action of the sex (follicular) hormone. PETER HAUPTSTEIN. *Endokrinologie* 8, 169–80(1931).—Studies on mice show that the effectiveness of the follicular hormone depends only up to a certain degree upon the amt. of the hormone administered. Repeating the dose at short intervals may increase its effectiveness even a hundred-fold. The loss of activity is rapid and independent of the dose and is apparently due to quick excretion. Following prolonged administration of nonphysiol amts. of the hormone there is definite evidence of injury of the follicular app. of the mouse, manifesting itself in inhibition of the follicular development and the failure of development of corpora lutea. The last fact is especially important in human therapeutics. S. MORGULIS

The chemical composition of animal fetuses. HAMDI ÖMER. *Arch. Wiss. Prakt. Tierheilkunde* 62, 248–66(1930).—Water, fat and ash were detd. in hog and sheep fetuses, and in hogs and sheep at various times shortly after birth. The water content of the fetus decreases, and the ash content and material free from fat and ash increase, as the fetus increases in size. The ash content of the fetus is less than that of the mature animal. W. GORDON ROSE

Partial diuresis. GIULIO LEGA. *Arch. farmacol. sper.* 51, 49–54(1930). —When 1000 cc. physiol. NaCl soln. was given to normal fasting humans, the NaCl was promptly excreted, while an increased water elimination became noticeable after 4–5 hrs. Urea administered in physiol. NaCl soln. to healthy persons was immediately excreted, while the elimination of water and NaCl was retarded. Daily administration of NaCl to nephrotics did not at first exert an influence on the NaCl excretion, which, however, began to rise after a few days. Administration of 500 cc. water to nephritics with polyuria and with glomerular and vascular lesions caused a retarded diuresis, if any. Protracted administration of urea to chronic nephritics with normal NaCl elimination and scanty urea exretion was followed in some cases by a prompt and prolonged urea excretion in the urine. In other cases with more severe lesions no urea was eliminated after administration of a single dose; in many of these cases, however, protracted urea administration was followed by increased elimination. No exptl. data are given G. SCHWOCH

Action of some organic and inorganic substances on the capacity for work of the gastrocnemius of the frog. VINCENZO FAMIANI. *Arch. farmacol. sper.* 51, 65–79 (1930).—One of the gastrocnemic muscles together with its nerve was isolated and immersed in a soln. of NaCl 0.60, KCl 0.03 and $CaCl_2$ 0.02% for 15 min. Then it was

put to work under isotonic conditions until it was completely exhausted. Meanwhile the substance to be tested was injected into the dorsal lymphatic sac of the frog. After 1 hr. (1.5 hrs. with glucose) the other gastrocnemius was isolated, immersed in the salt soln. for 15 min. and stimulated to complete exhaustion. From the muscular contractions as registered by the kymograph the work done was calcd. in g. m. and from the difference in work accomplished by the 2 muscles conclusions were drawn with regard to the favorable or unfavorable effect of the substance tested. Creatine, and to a slightly lesser degree NaH_2PO_4, caused an increase in the capacity for work. K_2HPO_4 in very small doses acted similarly, while in large doses it had an injurious effect. The influence of creatine in combination with K_2HPO_4 or NaH_2PO_4 was not greater than that of one of the compds. alone. Glucose alone or in combination with creatine or phosphates, or together with creatine and phosphates, always caused a distinct diminution in the work done. Other expts. showed that within certain limits the isolated gastrocnemius of the frog had a greater capacity for work the longer it had been immersed in the salt soln. All conditions being equal, the right muscle had a greater capacity for work than the left muscle. A large bibliography is included. G. SCHWOCH

The participation of the nucleolus of hepatic cells in iron metabolism. GIOVANNI CORRADINI. *Arch. farmacol. sper.* **51**, 125–8(1930).—By means of the Berlin blue reaction C. demonstrated that in the white mouse the nucleoli of hepatic cells participate in Fe metabolism. Normally the reaction is distinct only in the vicinity of the centrolobular vein, but after injection of colloidal Fe it was observed throughout the liver. Similar expts. on rabbits and guinea pigs showed that in these animals the Berlin blue reaction could not be produced in the nucleoli of the hepatic cells. G. SCHWOCH

Effect of experimental hyperthyroidism on reproductive processes of female albino rats. CHARLES K. WEICHERT. *Physiol. Zoöl.* **3**, 461–6(1930).—When normal female rats, which had shown regular estrous cycles, were fed with 0.25 g. of desiccated thyroid daily, the diestrous condition persisted as long as the thyroid feeding was continued (6–22 days). The animals came into estrus 2–10 days after feeding was discontinued. The general health of these rats was not markedly altered, though the body wt. had decreased approx. 19% after 3 weeks of thyroid feeding. Sections of the ovaries revealed a no. of corpora lutea along with follicles of all sizes. When pregnant mature rats were fed with desiccated thyroid (0.25 or 0.5 g. daily) very severe reactions followed. Some of the animals resorbed their young; others died before or after delivery. The gestation period was prolonged in those rats which lived long enough to deliver their young. The young were born dead or died within 1 or 2 days. The animals appeared to be in good health until the last 2 or 3 days of pregnancy. The reactions were more severe in the groups receiving the larger dose. The possibility is discussed that the anterior lobe of the pituitary body may be involved. G. SCHWOCH

Separation of anterior-lobe substances and study of their individual effects. PEARL L. CLAUS. *Physiol. Zoöl.* **4**, 36–57(1931); cf. *Proc. Soc. Exptl. Biol. Med.* **27**, 29–30.—Armour's desiccated anterior lobe was extd. with acid alc. In the attempt to sep. the hormones the method of Fevold, Hisaw and Meyer (*Proc. Soc. Exptl. Biol. Med.* **27**, 604) was used with some modifications. Two substances were isolated. One of them (I) was a constituent of a cryst. fraction; when injected subcutaneously it stimulated follicular development in adult female rats and induced early maturity in immature female mice and rats and in immature male mice. Identical crystals with the same physiol. properties were also obtained from urine of pregnant women, the epididymis of the bull, fish sperm, the thyroid gland and adrenal cortex. The other active fraction (II) was sol. in abs. alc. and contained a luteinizing hormone which was not obtained from a similarly prepd. ext. of adrenal cortex or epididymis. The luteinizing fraction caused, in the ovary of an adult rat, the formation of atretic corpora lutea with the ovum inclosed, but it did not induce early maturity. It also stimulated placentomata formation which does not occur with I. No increase in wt. was noticed after adult rats had been treated with I or II for 6 weeks. Numerous references and 6 plates are given. G. SCHWOCH

The formation of bile pigments in tissue cultures. I. SÜMEGI AND M. CSABA. *Magyar Orvosi Arch.* **31**, 473–7(1930).—The spleens of chicken embryos and those of amphibians are able to produce bilirubin in tissue cultures from laked blood. The bile pigments were identified by the indirect diazo reaction. Undissolved hemoglobin (erythrocytes from the explanates) produces bilirubin in the same way but only in trace. The formation of bile pigments is a vital function of the spleen. H. T.

The conditions of metabolism which can permit the change of sex. PH. JOYET-LAVERGNE. *Compt. rend.* **192**, 180–2(1931).—The changes of sex in animals, which have been described in recent years are attributed to simple physiol. causes: the change

from male to female to the deposition of fat in the testicles, the change from female to male to an increase in metabolism, a decrease in reducing power of the tissues and changes in the compn. of the blood. The last changes can be produced by tuberculous tumors (Crew, *Proc. Roy. Soc.* B95, 256, 1923) and are accompanied by the expected sex change. K. V. THIMANN

The relation between the effect of the estrus-producing hormone and a corpus luteum extract on the growth of the mammary gland. C. W. TURNER AND A. H. FRANK. *Science* 73, 295-6(1931).—Development of the mammary glands characteristic of pregnancy could not be obtained in rabbits by injection of the estrus-producing hormone alone. Injection of the hormone together with corpeus luteum ext. prepared by Allen's method (*C. A.* 24, 4819), however, gave after 30 days a development of the mammary glands of castrated males similar to that of advanced pregnancy. The active principle of the corpus luteum ext. responsible for this effect was present in a water- and EtOH-sol. ext. of the urine of pregnant cows, and this ext. could be substituted for the Allen's ext. in the above expts. K. V. THIMANN

Protoplasma-Monographien. Edited by FR. WEBER AND L. V. HEILBRUNN. **Band V.** PH. JOYET-LAVERGNE: **La physicochimie de la sexualité.** Berlin: Gebrüder Borntraeger. 457 pp. M. 32.

G—PATHOLOGY

H. GIDEON WELLS

A modified method for the production of antipneumococcus serum in horses. EDWIN J. BANZHAF AND THEODORE J. CURPHEY. *Proc. Soc. Exptl. Biol. Med.* 28, 279-80(1930).—Horses were immunized by intramuscular injections of phenolized pneumococcus pleural exudate and intravenous injections of formalinized sediment of 18-hr broth cultures. The sera of such horses had a greater therapeutic value than was indicated by their mouse protection unit content detd. by comparison with antiserum produced by administering vaccine intravenously. C. V. BAILEY

Is ferratin precipitinogenic? LUDVIG HEKTOEN AND WM. H. WELKER. *Proc. Soc. Exptl. Biol. Med.* 28, 293-4(1930).—Ferratin, a deriv. of nucleoprotein high in Fe, is obtained by boiling the liver, filtering and pptg. with tartaric acid. It can be rendered practically free from blood and lymph protein. Hog, beef and sheep ferratins were used in expts. on rabbits. The precipitinogenic power was slight and ferratin was not demonstrated to be a species-specific antigen. C. V. BAILEY

Antigenic power of ultra-violet-irradiated tetanus toxin. EMERSON MEGRAW AND HENRY WELCH. *Proc. Soc. Expt. Biol. Med.* 28, 494-5(1931).—A mixt. of 2 tetanus toxins dild. to contain 1 m. l. d. per cc. was irradiated with the C arc at 25 cm. distance for 2 min.; the toxin was partly destroyed; half the inoculated guinea pigs developed late tetanus. A further irradiation of 2 min. rendered the material atoxic. By use of a quantity originally contg. 1 m. l. d., 9 guinea pigs were given 5 subcutaneous injections of this irradiated toxin at 6–7 day intervals and were inoculated 3 weeks later with freshly titrated tetanus toxin in doses of 1–10 m. l. d. Tetanus did not develop in the 45 days of observation. Ultra-violet irradiation destroys the toxic but not the antigenic power of tetanus toxin. C. V. BAILEY

Absorption of hydrokollag from the obstructed bowel. H. A. CARLSON, H. J. DVORAK, F. W. LYNCH AND O. H. WANGENSTEEN. *Proc. Soc. Exptl. Biol. Med.* 28, 542-4(1931).—Hydrokollag, a colloidal suspension of graphite, was not absorbed from the obstructed intestine of the dog or of the rabbit. It was absorbed from the peritoneal cavity and possibly from the ulcerated intestine. C. V. BAILEY

Gastric acidity in diabetes mellitus. Its clinical significance based on a study of one hundred cases. I. M. RABINOWITCH, A. F. FOWLER AND B. A. WATSON. *Arch. Internal Med.* 47, 384-90(1931).—A study of normal cases shows a possible incidence of 20% who have achlorhydria. This incidence is, however, only one-half that found in diabetes mellitus, suggesting that this disease is accompanied by low gastric acidity. The etiology of this condition is discussed. J. B. BROWN

The metabolism of galactose. I. Conditions underlying the use of galactose in tests on the function of the liver. HARRY SHAY, EUGENE M. SCHLOSS AND MILTON A. BELL. *Arch. Internal Med.* 47, 391-402(1931).—Galactose is very suitable for testing liver function for the following reasons: readily obtainable pure; readily absorbed from the intestine; convertible with difficulty by the liver into glycogen; not utilized by other tissues than the liver; in the general circulation it is readily excreted in the urine, regardless of the condition of the kidney or endocrine activity. J. B. BROWN

The blood calcium in diabetic retinitis. R. D. LAWRENCE, KATE MADDERS AND

H. R. MILLAR. *Brit. Med. J.* 1930, II, 559.—The observation that diabetic retinitis is accompanied by low blood Ca is not confirmed. J. B. BROWN

The relationship of blood uric acid content to the state of renal function in nephritis. CHRISTOPHER JOHNSTON. *J. Clin. Investigation* 9, 555–9(1931).—Simultaneous detn. of blood uric acid and urea clearance showed the former to be of little value in the estn. of kidney function. Despite 80% loss of urea-excreting power by the kidney, uric acid may be normal. J. B. BROWN

The excretion of intravenously injected bilirubin as a test of liver function. GEORGE A. HARROP AND E. S. GUZMAN BARRON. *J. Clin. Investigation* 9, 577–87(1931).—The bilirubin excretory power is the most delicate method for testing liver function. J. B. BROWN

Studies of serum electrolytes. VII. The total base and protein components of the serum during lobar pneumonia with a note on the gastric secretion. F. WM. SUNDERMAN. *J. Clin. Investigation* 9, 615–33(1931).—Study of the base and protein constituents of the serum in patients with lobar pneumonia showed a decreased concn. of Na in proportion to the decrease in concn. of total base. In over half of the detns. an increase of K appeared before and after the crisis. During the febrile period Ca was decreased, while the Mg values were variable. A decrease in albumin was balanced by increase in globulin, making the total protein concn. nearly normal. Protein-bound base usually fell during the febrile period. Gastric acidity was low until after the crisis. There was no apparent correlation between serum total base or chloride with gastric acidity. J. B. BROWN

The cause of death in liver autolysis. EDMUND ANDREWS. *Surgery, Gynecol. Obstet.* 52, 61–6(1931).—Implantation of sterile liver (*in vivo* autolysis) produces a toxic reaction, described as autolytic peritonitis The toxic agent probably falls within the albumose group. J. B. BROWN

Action of parathyroid graft on calcemia in normal or parathyroidectomized dogs. J. T. LEWIS AND REBECA GERSCHMAN. *Compt. rend soc. biol* 103, 1281–3(1930).—See *C. A.* 25, 337. E. J. C.

Leucine and tyrosine in urine in lung tumors. HANS ASPERGER. *Wiener klin. Wochschr.* 43, 1281–4(1930).—Leucine and tyrosine are excreted in the urine in increasing quantities with the progress of carcinoma of the lungs. Their presence in the urine is of diagnostic value in doubtful cases. D. B. DILL

The influence of ergotamine and liver diet on liver function. RICHARD BAUER AND OSKAR WOZASEK. *Wiener klin. Wochschr.* 43, 1337–41(1930).—The administration of 40 g. of *galactose* results in *galactosuria* in some cases of liver disease when on a liver diet but does not occur with normal subjects on a liver diet. D. B. DILL

Distribution of electrolytes in serum and cerebrospinal fluid. I. Calcium and magnesium. ZDENKO STARY, ADALBERT KRAL AND RUDOLF WINTERNITZ. *Z. ges expl. Med.* 66, 671–91(1929); cf. *C. A.* 24, 3543.—The Ca content of cerebrospinal fluid approaches that of the dialyzable fraction of the serum. Dialysis of serum against spinal fluid produces only a slight change in the Ca distribution. The Ca content of cerebrospinal fluid is more constant than the serum Ca in the same individual, while Mg is the reverse. The spinal fluid Mg is higher than the serum Mg. A series of compensation dialysis experiments suggests that the serum Mg is in a complex anion. The ratio of Mg in spinal fluid and serum varied between 110 and 200% for non-meningitic cases. Tuberculous meningitis had a ratio less than 100%. **II. Potassium and sodium.** *Ibid* 691–701.—The K content of cerebrospinal fluid in a group of miscellaneous cases averaged 11.7 mg. % with an av. of 21.7 mg. % for the serum, giving a distribution coeff. of 53.92%; similarly for Na 295 mg. % for spinal fluid and 321 mg. % for serum, and a quotient of 91%. Dialysis of serum and cerebrospinal fluid results in both fluids having the same K concn. There were no characteristic changes in the distribution ratio of K or Na in the various diseases studied. F. L. DUNN

Behavior of free cholesterol and its ester in the blood and organs of the rabbit following artificial obstruction of the bile. E. VON ROSZTOCZY. *Z. ges. exptl. Med.* 68, 690–700(1929).—The rise in free cholesterol occurs in spite of the defective absorption of cholesterol resulting from the failure of the bile acids to be secreted because of the obstruction. The ester cholesterol showed a decrease in the organs while it was increased in the blood. The liver damage resulting from biliary obstruction is a factor in determining the relative amounts of free cholesterol and its ester. Part of the increase in cholesterol is due to the erythrocyte destruction accompanying biliary obstruction. The bibliography contains 75 references. F. L. DUNN

The specific dynamic action of protein in disturbed endocrine function. M. SEREISKII AND SOPHIE JISLIN. *Z. ges. exptl. Med.* 69, 321–36(1930).—Disease of the

thyroid resulted in a reduction or absence of the sp. dynamic action for protein. This change in hyperthyroidism was due to the satn. of the body with thyroid substance and to the over-stimulation of the vegetative nervous system. In hypothyroidism the lowered sp. dynamic action is a reflection of the general torpidity of bodily processes. The metabolism in thyroid disease is essentially endothermic in type. F. L. DUNN

Serum proteins in secondary syphilis. A. SEZARY AND P. MARTINET. *Bull. Mem. Soc. Med. Hopit. Paris* 1930, 945–7; *Bull. Hyg.* 6, 55.—The authors investigated the relation of albumin and globulin in the sera of 6 syphilitics in the secondary stage showing no nephrosis. The normal ratio is 1.6/1. The authors' figures range from 0.67 to 0.97/1. They assume the change due to changes in the metabolism brought about by spirochetal septicemia, not to nephrosis. GEORGE R. GREENBANK

Present status of the investigation of the cause, and of the geographical distribution, of mottled enamel, including a complete bibliography of mottled enamel. FREDERICK S. MCKAY. *J. Dental Research* 10, 561–8(1930).—"The evidence has been so overwhelmingly conclusive, to the effect that the productive influence resides in the drinking water, that the investigation now rests upon this hypothesis." The bibliography contains 47 references. JOSEPH S. HEPBURN

Cellular individuality in the higher animals with special reference to the individuality of the red blood corpuscle. II. CHARLES TODD. *Proc. Roy. Soc.* (London) B107, 197–205(1930).—Examn. of a family of Plymouth Rock chickens by means of exhausted immune iso-agglutinating sera revealed that the corpuscles of no 2 chickens were exactly alike; the cells of different individuals differed in immunological behavior from a close resemblance to a very marked contrast. Individual chickens, immunized with the blood of their own brothers and sisters, yielded active, highly sp. agglutinating sera. The ease of formation of the agglutinins varied with the degree of difference in character between the erythrocytes of the injected chicken and those used for immunization. "The red blood corpuscle must be regarded as a 'multiple antigen' in the sense that it contains a large number of different antigenic units or 'receptors,' which apparently behave as independent units when hereditarily transmitted." JOSEPH S. HEPBURN

Heat of rigor of mammalian muscle. E. C. SMITH. *Proc. Roy. Soc.* (London) B107, 214–22(1930).—Neither the disappearance of glycogen nor the formation of lactic acid suffices to explain the stiffening in rigor. A third chem. change, as yet not clearly understood, must also be involved. JOSEPH S. HEPBURN

Lactic acid content of the blood in several diseases, especially malignancy. E. M. GELSTEIN AND M. I. FRANKSTEIN. *Z. klin. Med.* 111, 563–81(1929).—The av. lactic acid content of the blood in healthy well-nourished persons is 9.08 mg. per 100 cc. It was increased in anemia, leucemia and cardiac disease with cyanosis and decreased oxidation in the tissues, and also in 56% of the cancer patients studied. A dose of 100 g. of dextrose or sucrose produced a temporary increase in the lactic acid content of the peripheral blood, the av. concn. being 66.9 mg. per 100 cc. at the end of 1 hr. This phenomenon was still more marked in some cancer patients. JOSEPH S. HEPBURN

Precipitation of sediments and the formation of calculi in the urinary tract. JOHANNES MEYER. *Z. klin. Med.* 111, 613–87(1929).—Pure uric acid calculi form in a normal, strongly acid urine with p_H approx. 5.0. Mixed calculi, composed of pure, quite dense uric acid, urate, oxalate and Ca phosphate layers, arise in normal urine of p_H 6.0. Pure Ca phosphate calculi form in normal neutral urine of p_H approx. 7.0. Hard, stratified calculi, composed chiefly of $MgNH_4PO_4$, Ca phosphate and NH_4 urate, form slowly in an ammoniacal urine with a faintly alk. reaction ($8 > p_H > 7$). If layers contg. considerable amts. of $CaCO_3$ be present in these calculi, then the reaction at their formation has been decidedly more alk. Soft free calculi, consisting chiefly of $MgNH_4PO_4$, $CaCO_3$ and NH_4 urate, form rapidly in a strongly alk. urine with $p_H > 8$. Org. compds. are simultaneously pptd., but the degree of satn. of the urine with crystalline compds. decides when the calculus grows, and the compn. of the deposited layers. An elaborate bibliography is appended. JOSEPH S. HEPBURN

Kidney function tests and blood-urea determination. H. KRUNKENBERG. *Arch. Gynäkol.* 143, 56–71(1930).—The various methods for detg. the functional activity of the kidney are reviewed. Most of them are too complicated for the average practitioner and require elaborate lab. equipment and often special prepn. of the patient. The detn. of the urea content of the blood by means of the azotometer is suggested as a reliable method for the average practitioner as the test is easily made and requires no special prepn. of the patient. HARRIET F. HOLMES

The xanthoproteic reaction in blood from which protein has been removed in pregnancy. H. EUFINGER. *Arch. Gynäkol.* 143, 366–75(1930).—The xanthoproteic reaction according to the method of Becher was carried out on blood from which the

protein had been removed from 80 pregnant women, 40 cases *sub partu* and 175 cases *post partum*. The xanthoproteic reaction was neg. during pregnancy and *sub partu*. *Post partum* a positive reaction was obtained in 45% and the reaction was obtained most often between the 5th and 10th days *post partum*. Fractionation of the total xanthoproteic content makes it seem probable that an increase of the intermediary aromatic amino acids is an indication of autolytic processes in the uterus in the puerperium. A pos. xanthoproteic reaction was obtained in 40% of the toxicoses of pregnancy, nephropathy and eclampsia. The xanthoproteic reaction is often markedly increased in cases of carcinoma of the uterus after x-ray or radium irradiation. Possibly the reaction will furnish a means for following the effect of irradiation in carcinoma cases. HARRIET F. HOLMES

Carbohydrate metabolism in cancer of the uterus after Röntgen and radium irradiation. I. LUCAS. *Arch. Gynäkol.* **143**, 389–411(1930).—In 10 cases of carcinoma of the uterus after treatment with x-ray or radium irradiation the sugar content and lactic acid content of the blood remain normal with the exception of a transitory increase in lactic acid content shortly after irradiation. The values for the alkali reserve indicate a hypocapnia of the blood. There was a decrease of alkali reserve 2–4 hrs. after the irradiation which was of short duration and 24 hrs. later there was an increase of alkali reserve which was slightly increased by each further irradiation. However, there is never a return to normal CO_2-binding power. The transitory increase in lactic acid shortly after irradiation coincides in time with the decrease in alkali reserve. The products of carbohydrate metabolism furnish no explanation for the persisting hypocapnia in patients with carcinoma of the uterus. HARRIET F. HOLMES

The Manoiloff reaction for pregnancy. F. FRETWURST AND K. OTTO. *Arch. Gynäkol.* **143**, 459–64(1930).—The Manoiloff reaction (*C. A.* **24**, 4315) for pregnancy was tried on sera from pregnant women, from healthy nonpregnant women and healthy men, and from patients with conditions that frequently give pos. results with other serological tests for pregnancy. The reaction was 61% pos. in the later months of pregnancy, but almost uniformly neg. in the earlier months of pregnancy. The reaction, therefore, is of no practical importance for the diagnosis of pregnancy. The reaction is not sp. HARRIET F. HOLMES

The two types of bilirubin diazo reactions in serum, with a hypothesis on the nature of the bilirubin in the serum from hemolytic jaundice. G. HUNTER. *Brit. J. Exptl. Path.* **11**, 415–9(1930).—An attempt has been made to det. the probable nature of the 2 kinds of diazo reactions for bilirubin obtainable in icteric sera. The so-called direct reaction, as it occurs in bile or in the serum of patients with obstructive jaundice, is most probably due to the presence of Na H bilirubinate. The so-called delayed reaction as it occurs in hemorrhagic exudates and in the serum of patients with hemolytic jaundice is probably due to the presence of free bilirubin in an undetd. solvent which is sol. in alc. The bilirubin solvent (it may be a lipoid or sterol) need be present in only relatively small amts. to retain the bilirubin in solution on the addn. of alc. The bilirubin may be in combination with its solvent or some other serum constituent so that it resists salt formation and oxidation. It would not be dialyzable or extractable with $CHCl_3$. H. thinks such a hypothesis to account for the delayed type of bilirubin would fit the findings better than the assumption of the presence of colloidal bilirubin. H. F. H.

Phosphorus, total calcium and diffusible calcium content of the blood sera of lepers and their relation to bone changes. JERALD G. WOOLEY AND HILARY ROSS. *U. S. Pub. Health Repts.* **46**, 641–58(1931).—Sera from 47 lepers were analyzed for Ca and inorg. P; the results were found to be within the range usually considered normal. Sera from 15 normal, healthy young men were examd. for inorg. P, total Ca, diffusible Ca, the % of Ca that was diffusible, the Ca-P and the diffusible Ca-P balance ratios were detd. Sera from 53 lepers, representing the various types and stages of progression of the disease, were similarly examd. The diffusible Ca and the % of total Ca that was diffusible averaged considerably lower in the lepers than in the normal young men, and in only a few instances did the diffusible Ca in the lepers approx. the level found in the controls. Radiographic studies of the bones of the hands and feet of 48 of these lepers showed bone atrophy in 44 (91.0%), the condition manifesting itself either as decalcification or absorption. The writers appreciate that the records here submitted do not include a sufficient no. of cases, observed over a sufficiently long period, to warrant the drawing of conclusions; it is thought, however, that deviation from the presumed normal has been marked enough to justify continuation of the investigation. J. A. KENNEDY

Antigenic value of scarlet-fever streptococcus toxin modified by the action of formalin. M. V. VELDEE. *U. S. Pub. Health Repts.* **46**, 693–8(1931).—V. briefly

reviews the data presented by various independent workers. The exptl. work here presented confirms the findings of others that scarlet-fever streptococcus toxin can be rendered much less toxic by subjecting it to heat and formalin. The antigenic value of the toxin apparently is not destroyed either by the action of the formalin or by the prolonged exposure to 37° to 38°. The amt. of antigen tolerated by susceptible individuals in each injection is greatly increased by this method of detoxification, so that the number of doses required for active immunization may be reduced. At the same time the reactions following the injections occur much less frequently and their severity is markedly diminished. Further experimentation may, it is hoped, develop a technic for removing the remaining toxic factor, thereby eliminating all disagreeable reactions and permitting the use of greater quantities of antigen. J. A. KENNEDY

The reactions of immunity among invertebrates. J. CANTACUZÈNE. *Arch roum. path. exptl. microbiol.* 1, 1–75(1928).—The introduction into the celom of *Sipunculus nudus* of sheep red corpuscles causes a certain no. of reactions on the part of the organism which have as their final effect the elimination of foreign particles in suspension in the cavity liquid, their reabsorption and the ultimate incorporation of the residue of this process into the brown bodies of the general cavity. The reabsorption is brought about solely by the phagocytes; the phagocytic action is facilitated by the agglutinant action of the viscous secretions. The process is characterized by an overproduction of all the cellular elements, and an intensification of their secretions, as well as a marked tendency toward agglutination and pptn. MARIE MAXIM

Investigations in the resistance of diphtheria and dysenteric toxin to different concentrations of hydrogen ions. C. IONESCO-MIHAIESTI AND A. DÂMBOVICEANU. *Arch roum. path. exptl. microbiol.* 1, 115–21(1928).—The destruction of the diphtheric toxin by the different concns. in H or OH ions is not immediate. For zone p_H 4.7–4.9 and 9.6–10.1 the toxicity is almost unchanged for 30 min. For 24 hrs. the limits are p_H 5.7–5.9 and 9–9.4. Likewise for dysenteric toxin the toxicity does not diminish until after a certain time; 30 min. in a medium of p_H 2.07–2.15 or p_H 11 does not suffice for any change; 24 hrs. of p_H 2.5–3 completes the action of the toxin. MARIE MAXIM

Appearance of a desensitizing and hypotensive substance in the organism after blocking of the reticulo-endothelial system. I. MODOVAN. *Arch. roum. path exptl microbiol* 1, 167–77(1928).—The intravascular or intraperitoneal injection of substances provoking the blocking of the reticulo-endothelial tissue brings about in the serum of inoculated animals the appearance of a desensitizing, hypotensive, thermo resistant substance, sol. in acids, alc., water, easily dialyzable through membranes of collodion and which has not been identified. MARIE MAXIM

Investigations on blood lipase in different forms of tuberculosis. I. NICOLAU AND O. ANTINESCU. *Arch. roum. path. exptl. microbiol.* 1, 437–51(1928).—Fat, detd according to the stalagmometric method, is generally diminished in the blood of tuberculous patients; its variations are in relation to the general state of the sufferer and not to the degree of tuberculous lesion. MARIE MAXIM

The glycogenesis of the sarcoma of Peyton Rous. E. C. CRACIUN. *Arch. roum. path. exptl. microbiol.* 2, 105–11(1929).—The sarcoma of Rous presents a quite abundant and irregular glycogenesis at the level of coagulation necrosis as well as with liquefying necrosis. There is no relation between the glycogenesis and the virulence of this tumor. MARIE MAXIM

Investigations on specific substances (residual antigens) of the anthrax bacilli. D. COMBIESCO, E. SORU AND S. STAMATESCO. *Arch. roum. path. exptl. microbiol.* 2, 291–312(1929).—A water-sol. substance having the properties of polysaccharides has been sepd. from *B. anthracis*. This substance is not toxic for white mice and guinea pigs, does not form antibodies and gives a pptn. with specific serums. The rotary power after hydrolysis is —20; it contains hexoses and pentoses. MARIE MAXIM

Glycogenesis and regeneration of voluntary muscles. E. C. CRACIUN. *Arch roum. path. exptl. microbiol.* 2, 313–23(1929).—The sarcoblasts and granulation tissue contain no glycogen; this substance is often present in abscesses. M. M.

The heliotropic property of cholesterol in relation to cancer of the skin. A. H. ROFFO AND FR. PILAR. *J. physiol. path. gén.* 28, 854–6(1930).—Exposure of the skin to sunlight or ultra-violet light increases its cholesterol content. In the authors' experience 92% of the skin tumors of the face occur on parts directly exposed to the sun. They conclude that there is a relationship between the heliotropic properties of cholesterol, its fixation in the skin and tumor formation. L. A. MAYNARD

The chemical investigation of lung tissue in pneumoconiosis. LUIS ROSSI AND SANTIAGO A. CELSI. *Semana méd.* (Buenos Aires) 1931, I, 629–34.—In the lungs of

miners in Bolivia, SiO_2, Fe, Al and Sn were found, the last at a ratio of 1.0963% calcd. on dry or 0.272% calcd. on fresh substance. A. E. MEYER

Studies on the subfractions of the serum globulins and albumins. II. The distribution of lipoids, precipitinogens and bacterial agglutinins among the separate fractions of serum. B. LUSTIG AND R. KATZ. *Biochem. Z.* **231**, 39–44(1931).—The largest lipoid content is found together with the albumin and the smallest with the euglobulin fractions of serum. Among the subfractions of euglobulins and pseudoglobulins the highest total lipoid and lecithin content is found in the proteins sol. in NaCl and the smallest in the water-sol. ones. The largest amt. of the sp. precipitinogen is also in the NaCl-sol. euglobulins and pseudoglobulins and the least in the albumin fractions I and II. Normal agglutinins are chiefly associated with the euglobulin and are practically absent in the albumins. Among the globulins the Na_2CO_3-sol fraction has the largest amt. of agglutinin while the NaCl-sol fraction has the smallest amt. **III. Elementary composition, distribution of amide nitrogen, humin nitrogen, diamino nitrogen, mono- or non-amino nitrogen, of tryptophan, and of carbohydrate in the separate subfractions of cow serum.** B. LUSTIG AND P. HAAS. *Ibid* 472–92(1931).—The water absorption (% increase in wt. of dry powder suspended in H_2O) of the different serum protein fractions is as follows: water-sol. euglobulin 8.8–12.3%, NaCl-sol. euglobulin 9.6–13%, Na_2CO_3-sol. euglobulin 8.3–10% and NaOH-sol euglobulin 8.3–12.8%, water-sol. pseudoglobulin 8.8–11%, NaCl-sol. pseudoglobulin 8.1–12.5%, Na_2CO_3-sol. pseudoglobulin 6.8–9.5%, albumin I 10.5–14%, albumin II 9.5–12.5% and albumin III 8.0–12.8%. The elementary compns. of the different fractions, in the same order, are: % C 51.89, 52.44, 55.76, 49.51; 53.02, 54.59, 57.14; 53.70, 53.27, 55.82. % H 6.38, 6.39, 7.27, 6.32; 6.75, 6.91, 7.53; 7.25, 6.71, 7.31. % N 15.25, 15.96, 13.84, 9.83; 14.05, 15.45, 13.25; 15.43, 14.68, 15.92. % S 1.53, 1.55, 1.71, 1.57, 1.64, 1.34, 1.28; 2.37, 2.18, 2.27. % P 0.06, trace, 0.15, 0.24; 0.12, 0.20, 0.06; 0.07, 0.06, 0.15. % CH_3 on O 0.46, 0.66, 0.49, 0.47; 0.95, 0.42, 0.63; 0.57, 0.06, 1.04. % CH_3 on N 0.79, 1.50, 0.57, 0.38, 0.43, 0.83, 0.68; 0.93, 0.58, 0.66. The percentages of amide N in the different fractions were 4.5, 1.5, 3.2, —; 4.3, 1.6, —; 4.8, 4.3, —; of humin N, 4.8, 2.1, 2.2, —; 4.2, 1.9, —; 1.5, 1.7, —; of diamino N, 23.6, 26.5, 27.0, —; 21.8, 26.0, —; 32.5, 32.7, —; of mono- and non-amino N, 68.2, 71.8, 61.8, —; 72.2, 68.1, —; 63.8, 62.5, —. The av. percentages of carbohydrate were 0.84, 0.98, 2.38, 8.50; 0.98, 0.64, 6.40; 0.47, 0.55, 0.65. S. MORGULIS

Studies on antiricin. FRITZ REUTER. *Biochem. Z.* **231**, 175–232(1931).—The antiricin is adsorbed with kaolin from an anti-serum. The relation of the antiricin to the serum proteins is thereby not affected since the latter are likewise adsorbed, the adsorption of both being proportional to the quantity of kaolin. The adsorption is complete in 10 min., neither the order of mixing nor the degree of dilu. of the serum being of any consequence. Small amts. of kaolin adsorb the antiricin and proteins without reacting NH_2 groups, whereas with larger amts. proteins with reacting NH_2 groups also appear. A *M*/3 phosphate buffer of p_H 7.17 leaches out the antiricin only to a small extent, but this is improved by the addn. of normal serum to the buffer. NaCl does not leach out the antiricin even in the presence of a great excess of serum. Infusorial earth C is an excellent adsorbent, and the antiricin can be very well leached out with phosphate buffer (not with NaCl), the ease depending upon the concn. of the buffer. Evidently the PO_4 ions are essential for the leaching out. With increasing acidity of the buffer soln. it becomes less suited for leaching out purposes. Furthermore, the PO_4 ions also tend to displace the protein and antiricin from the adsorbent, since the latter treated with phosphate loses some of its adsorbing power. The leaching out was repeated 3 times, most of the antiricin together with most of the protein being removed after the first leaching, each successive leaching, however, removing a const. portion of the antiricin present in the adsorbent. The second leaching yields antiricin poorest in protein. Through fractional pptn. with $(NH_4)_2SO_4$ much protein can be removed without affecting the antiricin content. Further purification can be effected through electrodialysis, etc. Antiricin is not attacked by proteinase, carboxypolypeptidase or trepsin. S. MORGULIS

Rose bengal in the examination of the liver function. ALFREDO RICCI. *Arch. farmacol. sper.* **51**, 25–31(1930).—R. concludes from the analysis of liver-function tests on 12 patients that with the Rose bengal test the eliminating power of the liver, but not the entire functional ability of the hepatic cells, is detd. When bile pigment or urobilin is found in the urine and when the Rose bengal test is positive, the functional ability of the liver is altered. The reverse is not true, however, since the elimination may be normal, though the more complex functions of the liver may be impaired. G. SCHWOCH

The gastric secretion in fasting patients. FLAMINIO RICCI. *Arch. farmacol.*

sper. 51, 55–63(1930).—In 70 patients with gastric disturbances the gastric secretion was studied with respect to quantity of fluid, free HCl and total HCl. The samples were taken from patients in the fasting state or after a meal. In the patients in the fasting state a distinction is made between the "immediate secretion" which represents the 1st sample taken and the "late secretion" comprising samples taken after the removal of the 1st sample, in 10-min. intervals for the following 30 min. An "immediate fasting secretion" was found in 94% of the cases. In 72% the quantity of juice was less than 40–45 cc. Quantities in excess of 40 cc. were found in diseases assocd. with hypersecretion. Quantities larger than 60 cc. contained food residues and were due to pyloric stenosis. Free HCl was found in 78.57% of the cases; this percentage increases with the "late secretion" or after a meal. In general the immediate fasting secretion varied with the different gastric disorders and a relation between secretion and disease could be established. In diseases assocd. with hyperchlorhydria the secretion was generally abundant (25–60 cc.), while in diseases with normal or subnormal HCl the secretion was small (5–25 cc.). In the diseases with little secretion the content of free HCl was very slight. About 30 cc. is considered as the normal immediate fasting secretion. The "late secretion" was in general more abundant in cases with hyperchlorhydria and less abundant in cases with hypochlorhydria and anachlorhydria; the av. quantity secreted within 30 min. is 35–50 cc. The content of free HCl was generally greater in the late secretion than in the immediate secretion and slightly smaller than in the secretion after the meal. The late secretion was quite frequently (30%) contaminated because of duodenal regurgitation; therefore this test is only of relative value. The importance of the examn. of the fasting gastric secretion is emphasized with respect to its value in the diagnosis. G. Schwoch

Uricidemia in diabetes mellitus. Alfredo Ricci. *Arch. farmacol. sper.* 51, 41–8(1930).—The uric acid of the blood was detd. in 18 fasting diabetic patients who in the days previous to the expts. had been given a diet low in purine-contg. foods. The uric acid was normal in the cases treated with insulin and was increased in the cases not treated with insulin. Since the detns. were carried out according to the method of Folin and Denis, and since xanthine and guanine give the same reaction with this method, R. assumes that the oxidation of the intermediate products in the purine metabolism, for which the kidneys are impermeable, is retarded, thus giving rise to the accumulation of these products in the blood. This hypothesis is supported by expts. which were conducted to exam. the degradation of the exogenous purine substances. One normal person and 11 diabetics were given a meal consisting of 150 g. liver and 50 g. calf's tripe. Three hrs. later the uric acid was elevated in the healthy person and 6 hrs. later it had almost returned to its initial value. In the diabetics the uric acid was increased after 3 hrs. and was still far above normal after 6 hrs. The uric acid curve of the diabetic treated with insulin was similar to that found in the normal person. These results indicate that the purine metabolism is intimately linked with the carbohydrate metabolism; when the latter is deranged, as in the diabetic, the purine metabolism is also affected. Insulin administration to diabetics restores the carbohydrate metabolism to normal and consequently the purine metabolism is also restored to normal. G. S.

Chloremia and azotemia in cardiopaths. Serafino Manca. *Arch. farmacol. sper.* 51, 81–94(1930).—Urea N and Cl of the blood and Cl of the urine were detd. in 20 patients with heart disease who had been kept on a const. diet for 2 or 3 days before the test. The patients with compensated heart disease showed values similar to those obtained from 8 healthy people. In the patients with non-compensated heart disease the Cl of the blood and urine was diminished, while the non-protein N of the blood was augmented. The more the non-compensated state was reduced by proper treatment the more the Cl and urea N approached normal values, without ever completely equaling them. These findings are probably related to the fact that in these cases slight renal lesions persist even after compensation has occurred. G. Schwoch

Lactacidemia in renal insufficiency. Alfredo Ricci. *Arch. farmacol. sper.* 51, 141–4(1930).—Lactic acid was absent in the plasma of 12 patients with partial renal insufficiency; it was present (0.019 and 0.015%) in 2 cases of complete renal insufficiency. Its presence signifies an unfavorable prognosis. G. Schwoch

The question of the effect of unilateral eye extirpation. Bernhard Do
sunlight
92% of the *neralis* 6, 511–52(1930).—D. had found in the course of earlier investigation
conclude that there after unilateral eye extirpation the normal development of the midbr
fixation in the skin and tunic rated eye is inhibited. The controls developed normally in u

The chemical investigation ts. revealed that the water used in those expts. conta
Santiago A. Celsi. *Semana me* ated from a zinc-plated storage basin. Recent inv
s the development of extremities, midbrain and eye,

inhibited also in non-operated animals when a relatively large amt. of Zn was present in the water. However, the eye extirpation was an aggravating factor, since all of the operated larvae, when kept in the water with high Zn content, developed the symptoms mentioned. With the exception of the immediate consequences of the operation no disturbance was exhibited by the operated animals kept in Zn-free water. G. S.

The chlorine content in the blood of tuberculous infants during the tuberculin shock. IGNAZIO GATTO. *Pediatria Rivista* 39, 143–9(1931); cf. *C. A.* 25, 339.—Expts. on 10 infants with active tuberculous foci showed that the Cl content of whole blood was diminished during the tuberculin shock. The ratio corpuscular Cl : plasma Cl decreased first, but it increased during the period of the max. febrile reaction.
G. SCHWOCH

Experimental contribution to the study of rickets. CAMILLA NERVI. *Pediatria Rivista* 38, 1268–78(1930).—The amt. of inorg. P found in the blood of children with rickets appeared to be slightly lower than that found in normal children; however, no relation existed between inorg. P and the severity of the rachitic lesions. Detn. of the inorg. P of the blood in rachitic children showed that after ingestion of a meal the behavior of the P curve is similar to that observed in normal children. In rats kept on a rachitogenic diet no relation was found between the inorg. P of the blood and the extent of the rachitic lesions
G. SCHWOCH

The effect of acid and alkaline food on the growth of mouse carcinoma. I. MARTON, G. MAGASSY AND A. LESZLER. *Magyar Orvosi Archivum* 31, 59–64(1930).—The growth of transplanted mouse carcinoma is retarded by food contg. $(NH_4)_2HPO_4$ or $(NH_4)H_2PO_4$, which are known to cause acidosis. On the other hand, tumor growth is accelerated by food contg. $NaHCO_3$, which causes alkalosis. H. TAUBER

Tumor immunity. THOMAS LUMSDEN. *Am. J. Cancer* 15, 563–640(1931).—If the euglobulin is pptd. from an anti-malignant-cell serum (by dilg. the serum with distd. water and adding enough AcOH to bring the mixt. to the isoelec. point) a soln. of the ppt. in normal rat serum is as toxic to cultures of cancer cells as the original anti-malignant-cell serum itself. Euglobulin pptd. from the serum of a sheep which has been immunized against human breast cancer can be redissolved in Ringer soln. or normal mouse serum to the original vol. of the serum from which it was made, and, when recomplemented, kills cultures of mouse cancer (M_{63}) or sarcoma (A_{37}) as rapidly as the iginal serum. This fraction (euglobulin), therefore, contains the anti-malignant-cell odies. This euglobulin fraction is even more specifically anti-malignant than the iginal anti-human-breast-cancer serum itself, since in the process of pptn. most of the terotoxins present are destroyed. Hence, if the redissolved and recomplemented globulin is applied to a mixed culture of mouse cancer and mouse normal tissues, all e cancer cells are killed in a few min., while the normal tissue cells are quite undamaged id continue to divide and migrate out actively. The euglobulin fraction of the serum a rabbit immunized against mouse sarcoma kills, when recomplemented, cultures of ouse carcinoma, but does not damage cultures of mouse heart cells nearly so rapidly or verely. The pseudoglobulin pptd. from the serum of the sheep immunized against man cancer is not toxic to cultures of normal mouse tissues, but it causes mouse ncer cells to agglutinate. The cytolytic effects produced by the euglobulin fraction on ouse cancer cells are not observed if the pseudoglobulin is pure. This pseudoglobulin action is still toxic (cytolytic) to human cancer cells, which suggests that anti-species odies are contained in it. They demonstrate conclusively the fact that antibodies hich are specifically lethal to malignant cells exist. These antibodies can be pptd. out the appropriate sera, can be in this way refined and concd., and when redissolved and complemented are as potent as before pptn. The fact that they are toxic to malignant lls of all varieties, and from any species of animal, strongly suggests that some special ntigenic factor is common to all malignant cells. These cells all have certain common haracteristics, such as the power of indefinite multiplication, dedifferentiation, etc. ence it would have been surprising if they had not had as a common basis for these eculiarities some common constituent capable of acting as an antigen.
H. G. WELLS

Biochemical studies of malignant conditions. JOSEPH H. ROE AND HELEN M. YER. *Am. J. Cancer* 15, 725–31(1931).—Glucose-tolerance tests showed a lowered arbohydrate tolerance in fowls bearing the Rous sarcoma No. 1. The reduced carbohydrate tolerance is probably secondary to changes produced in the organs regulating arbohydrate metabolism, either by metastases or by a toxemia due to the malignant owth. The glycogenolytic activity of the blood of hens in which the Rous sarcoma . 1 had developed showed no variation from that of normal controls. The blood of wls bearing the Rous sarcoma No. 1 has a glucolytic activity about twice as great as

that of normal fowls. This is a primary change resulting apparently from an overflow into the blood stream of the glucolytic enzyme, which Warburg showed to be in tumor tissue in greatly increased amounts. An examn. of the glucolytic activity of the blood of 16 patients with malignant tumors gave values that are within normal limits. The detn. of the glucolytic activity of the blood is, therefore, of no clinical value in studying malignant conditions. The discrepancy between the glucolytic activity of the blood of hens with the Rous sarcoma No. 1 and that of the blood of patients with malignant conditions is probably due to the greater ratio of tumor tissue to normal tissue in the fowls with the sarcoma. H. G. WELLS

Immunological relationships among the pneumococci. V. Anaphylaxis and precipitation between antigens and antisera of yeast of type II pneumococci. JOHN Y. SUGG AND JAMES M. NEILL. *J. Exptl. Med.* 53, 527–34(1931).—A report is given of the interactions of anaphylaxis and pptn. between antigens and antisera derived from Type II variety of pneumococcus and from one variety of yeast. That the reactions occurred only with Type II and not with Types I and III is proof that the pneumococcus antigen responsible for the anaphylaxis of the antiyeast-sensitized animals was the type-sp. carbohydrate (S). C. J. WEST

Bilirubinemia. E. S. GUZMAN-BARRON. *Medicine* 10, 77–133(1931).—An exhaustive critical review of the literature of the physiology and chemistry of bilirubin, methods of detn. and their clinical application, with a bibliography of 290 references. H. G. WELLS

Biochemistry of Rous sarcoma of fowls. I. Biophysics. V. Coagulation of the serum. JIŘÍ HOLÝ. *Z. Krebsforsch.* 33, 133–45(1930); cf. *C. A.* 24, 5858.—In all cases the quantity of serum proteins of normal fowls showed wide variations, quite as great as in disease, and the proteins show the same coagulation properties, whether normal or pathol., with most precipitants. With $CuSO_4$ and $Cd(NO_3)_2$ some irregular differences were obtained. VI. Alterations in the crystal form of sodium chloride. *Ibid* 146–54.—A difference was found in the crystal forms when serum from normal and sarcomatous fowls was evapd. to dryness. H. G. WELLS

Vitamin A content of melanosarcoma of horses. SK. V. GUDJONSSON. *Z. Krebsforsch.* 33, 155–7(1930) —The amt. present in the tumors and in the adjacent muscle tissue is very small. H. G. WELLS

Sulfur impoverishment of the body and the tendency to cancer. GRUMME. *Z. Krebsforsch.* 33, 376–7(1931).—Purely speculative. H. G WELLS

The stimulation of epithelial growth with synchronous disturbance of connective tissue growth in tissue cultures by substances which affect surface tension. M KATZENSTEIN AND ELSE KNAKE. *Z. Krebsforsch.* 33, 378–410(1931).—Substances with high surface effects have a sp. action on tissue cultures of the chicken embryo. Cholesterol or amyl alc. depresses connective tissue growth and stimulates epithelial proliferation. Other substances exert a similar effect in direct proportion to their surface effects. H. G. WELLS

The American Journal of Clinical Pathology (*New journal*). Published bimonthly by the American Society of Clinical Pathologists at Mount Royal and Guilford Aves., Baltimore, Md. Vol. 1, No. 1 appeared Jan., 1931. $5 per year.

A. N. RICHARDS

Avertin. F. B. PARSONS. *Brit. Med. J.* 1930, II, 554–7; cf. *C. A.* 24, 5373.—A review of the chem. properties and the clinical uses of this drug. J. B. BROWN

Sodium amytal and other derivatives of barbituric acid. L. G. ZERFAS. *Brit. Med. J.* 1930, II, 897–902.—A review. J. B. BROWN

The elimination of ethyl iodide after inhalation and its relation to therapeutic administration. HERRMAN L. BLUMGART, DOROTHY ROURKE GILLIGAN AND JACOB H. SWARTZ. *J. Clin. Investigation* 9, 635–50(1931).—Following the introduction and inhalation of 1 to 3 cc. of EtI in the inspired air, 45% is immediately exhaled during the treatment, 9% is exhaled during the next 2 hrs. and 31% is excreted by the kidneys as iodide. A total of 85% of the dose is accounted for, the remainder being probably excreted in the sweat, etc. Eighty-five % of the urinary excretion appears in the first 24 hrs. and 97% in 48 hrs. To maintain high iodide concn. in the body daily administration must be given, the treatment being omitted every 3rd or 4th day to avoid iodism. The % of EtI retained in the body is independent of the size of the dose. J. B. BROWN

Studies in congestive heart failure. VIII. The effect of the administration of

dibasic potassium phosphate on the potassium content of certain tissues. J. ALFRED CALHOUN, GLENN E. CULLEN, GURNEY CLARKE AND T. R. HARRISON. *J. Clin. Investigation* 9, 693–703(1931); cf. *C. A.* 25, 1283.—Detns. of total solid and K were made on skeletal muscle, cardiac muscle from both ventricles and on liver and kidney in subjects dying without cardiac disease, with congestive heart failure without K and with congestive heart failure when K was administered during life. The controls showed a higher K content in both wet and dry tissues than the heart failure cases. The administration of K to the heart cases increased the tissue K, but the difference was most striking with skeletal muscle and least in heart muscle. J. B. BROWN

The toxicity and balantidicidal action of "di-hydranol" in guinea pigs. NORMAN A. DAVID AND CHAUNCEY D. LEAKE. *Proc. Soc. Exptl. Biol. Med.* 28, 196–9(1930).—"Di-hydranol" (2,4-dihydroxyphenyl-*n*-heptane) caused death in the guinea pig in about 4 days with symptoms of loss of wt., diarrhea and lethargy at an av. single dose of 400 mg. per kg. of body wt. It cures *Balantidium coli*-infested guinea pigs when given in doses of 75–100 mg. per kg. at 1–2 day intervals until the total amt. administered is 200–225 mg. per kg. of body wt. Doses slightly higher than the curative range may be toxic. C. V. BAILEY

Value of hexuronic acid in the treatment of Grave's disease with suprarenal cortex. DAVID MARINE, EMIL J. BAUMANN AND BRUCE WEBSTER. *Proc. Soc. Exptl. Biol. Med.* 28, 327–9(1931).—Marked clinical improvement followed the oral administration of a glycerol ext. of fresh ox suprarenal cortex in patients with Grave's disease. A hexuronic acid, readily destroyed by exposure to air, had been found in suprarenal cortex (cf. *C. A.* 23, 1423). Large doses of hexuronic acid concentrate, 400 mg. twice daily, given by mouth did not relieve the symptoms of Grave's disease and did not add to the therapeutic value of the suprarenal cortex ext. C. V. BAILEY

Effects of the halogenation of hydroxyquinoline on biological activity. H. H. ANDERSON, N. A. DAVID AND DOROTHY A. KOCH. *Proc. Soc. Exptl. Biol. Med.* 28, 484–5(1931).—Toxicity increased with halogenation of hydroxyquinoline and in proportion to the at. wt. of the halogen. The addn. of both I and Cl to hydroxyquinoline caused a considerable increase in toxicity which was slightly reduced by the addn. of a solubilizing group. The balantidicidal action in naturally infested guinea pigs was also increased by halogenation. In monkeys naturally infested with *Endameba histolytica*, 900 mg. per kg. of body wt. of iodochlorohydroxyquinoline given in divided doses over a 6 weeks' period eradicated the amebae. C. V. BAILEY

Blood-sugar response to intravenous insulin in normals and in diabetics. WM. S. COLLENS AND HAROLD G. GRAYZEL. *Proc. Soc. Exptl. Biol. Med.* 28, 487–9(1931).—Equivalent intravenous doses of insulin on the basis of body wt. produce a much greater depression in the blood sugar level in diabetic than in normal man. The absence of an insulin-inhibiting substance in the blood of diabetics is inferred. C. V. BAILEY

Parathyroid and fluoride hypocalcemia. R. GERSCHMANN. *Compt. rend. soc. biol.* 104, 411–2(1930).—See *C. A.* 25, 348. E. J. C.

Parathyroids and hyperglucemic curves. R. GERSCHMANN. *Rev. soc. Argentina biol.* 6, 35–9(1930).—See *C. A.* 25, 348. E. J. C.

Bromide poisoning with the picture of typhus abdominalis. HEINRICH MAYRHOFER AND ALFRED FESZLER. *Wiener klin. Wochschr.* 43, 1315–6(1930).—A case is described. D. B. DILL

The comparative effects of diuretics containing mercury. ELISABETH BERGER. *Wiener klin. Wochschr.* 43, 1505–8(1930).—The diuretic properties of NH_4Cl, NH_4Br and HCl are due to acid formation in the organism. They are used together with *salyrgan* and *decholin* when these alone are ineffective. D. B. DILL

The effect of age upon the action of thyroxine. EMIL ABDERHALDEN AND ERNST WERTHEIMER. *Z. ges. exptl. Med.* 68, 1–19(1929).—Loss of weight and toxicity are more marked in older or heavier guinea pigs and rats when given thyroxine than in younger or lighter animals. The glycogen losses are more marked in the older animals. No definite differences were made out with regard to gaseous and N metabolism at different ages, following administration of thyroxine. Increasing the dosage of thyroxine from 0.3 to 3 mg. per day in young animals results in but very little increase in toxicity. F. L. DUNN

Ketonuria in experimental hyperthyroidism. I. ABELIN AND A. JORDI. *Z. ges. exptl. Med.* 68, 20–31(1929).—Following thyroid ext. feeding or injections of thyroxine in rats there is an excretion of acetone, diacetic acid and β-hydroxybutyric acid in the urine, the last being in greatest amt. Maximal excretion occurs on the 10–14th day. It is much less than that observed following phlorhizin or alkaloids. F. L. DUNN

The influence of thyroxine on the blood iodine in myxedema. B. EISLER AND

A. SCHITTENHELM. *Z. ges. exptl. Med.* **68**, 487–92(1929).—The I content of the blood is markedly lowered in myxedema. Thyroxine administration (oral or intravenous) raises the blood I above the normal values for a short period after which it remains normal. The blood I in normal individuals is not altered by thyroxine feeding.
F. L. DUNN

Mechanism of action of small doses of salts and "Trunecek-serum." K. I. KOTELNIKOV. *Z. ges. exptl. Med.* **69**, 297–320(1930).—Subcutaneous injection of inorg. salts (5–15–25 mg.) and Trunecek-serum results in definite changes in the acid-base balance measured by alveolar air CO_2.
F. L. DUNN

Intravenous injection of ethyl alcohol for anesthesia. I. I. NITZESCU. *Compt. rend. soc. biol.* **104**, 25–8(1930).—See *C. A.* **24**, 5865.
G. G.

Action of arsenite on tissue respiration. ALBERT SZENT-GYÖRGI. *Biochem. J.* **24**, 1723–7(1930).—Arsenite strongly inhibits respiration of minced liver tissue, but has no effect on O activation, and little effect on H activation. In yeast, arsenite in higher concns. inhibits respiration but has no effect on alc. fermentation.
B. H.

Ethylene and carbon dioxide. JAMES TAYLOR GWATHMEY AND M. HILLEL FELDMAN. *Dental Cosmos* **72**, 1164–6(1930).—The use of C_2H_4, N_2O, CO_2 and O_2 for general anesthesia is described.
JOSEPH S. HEPBURN

Effects of strontium administration on the histological structure of the teeth of rats. HENRY KLEIN, J. ERNESTINE BECKER AND E. V. MCCOLLUM. *J. Dental Research* **10**, 733–8(1930).—A ration, adequate in all respects except its Ca content and contg. Sr chemically equiv. to 0.6% Ca, produced a proliferation of dentinoid, *i. e.*, the uncalcified ground substance, when fed to rats.
JOSEPH S. HEPBURN

Contraction of the extrinsic muscles of the eye by choline and nicotine. W. S. DUKE-ELDER AND P. M. DUKE-ELDER. *Proc. Roy. Soc.* (London), **B107**, 332–43(1930). —Choline, acetylcholine and nicotine produce a slow, tonic contraction of the normal extrinsic muscles of the eye, which is unaffected by atropine, increased by adrenaline and abolished by nicotine plus curare.
JOSEPH S. HEPBURN

Experimental addiction of animals (monkeys) to opiates. LAWRENCE KOLB. *U. S. Pub. Health Repts.* **46**, 698–726(1931).—The relative effects in the order of their severity of the 3 drugs given to monkeys in one toxic dose or in smaller daily doses were: toxicity; *heroin* was decidely most toxic, *morphine* least toxic; general health: *codeine* was decidedly most harmful, *heroin* least harmful; dependence-producing properties: *morphine* was most potent, *codeine* very slight or nonexistent.
J. A. KENNEDY

Intraperitoneal iron. CLIFFORD G. GRULEE AND HEYWORTH N. SANFORD. *Am. J. Diseases Children* **41**, 53–61(1931).—Fe injected intraperitoneally into rabbits becomes deposited in the liver rather than in the spleen. The hemoglobin and erythrocyte contents of the blood remain unchanged. The intraperitoneal administration of Fe to children with secondary anemia appears to be a safe and easy way of introducing Fe into the organism and creating a reservoir upon which the body may draw. Following the intraperitoneal injection of 5–8 mg. of Fe, as colloidal $Fe(OH)_3$, at 3-day intervals, the hemoglobin content of the blood and the no. of erythrocytes become markedly increased. The injections are combined with exposure to ultra-violet light or with blood transfusions.
E. R. MAIN

The blood constituents in acute rheumatism before and after salicylate treatment. EVELYN M. HICKMANS AND SIDNEY H. EDGAR. *Arch. Disease in Childhood* **5**, 387–96 (1930).—The urea, non-protein N and uric acid contents of the blood are somewhat higher than normal in acute rheumatism. The values tend to remain high during treatment with salicylate. The urea tends to become increased after the treatment while the administration of the same quantities of salicylate to normal children does not affect the urea content of the blood. The treatment with salicylate may further decrease the degree of renal efficiency in acute rheumatism.
E. R. MAIN

Quantitative studies on local anesthetics. A. RABBENO. *Boll. soc. ital. biol. sper.* **5**, 1094–8(1930).—The method used consisted in the application, to the dorsal skin of the leg of the decerebrated frog, of a rectangular piece of cotton satd. with the soln. under examn.; this was left for a definite time, and the reflexes were tested with disks of paper wetted with *N* AcOH. By varying the time of application of the drug, at const. concn., the min. time necessary to obtain the abolition of the reflexes is detd. and with successive tests at varying concns. a curve of the min. time of anesthesia as a function of the concn. of the drug is obtained. The curve is bound by 2 limiting values of concn.: the one which provokes immediate anesthesia (1 min.) and that which acts after several hrs. of application. Pyrryl alkyl or aryl ketones: (α-acetyl-, α-propionyl-, α-butyryl-, α-benzoylpyrrole). The curve which graphically represents the manner with which the min. time of anesthesia of pyrryl ketones varies with varying concns. of the drugs is

an arc of an hyperbola, represented by the equation $y = a + (b/x)$ (1), where y = min. time, x = concns., a and b are consts. When $y = 0$, $x = b/a$, that is, for zero time, the curve intersects the axis of x at a concn. equal to $-b/a$. For concns. equal to or greater than this, anesthesia is almost immediate. From the intersection at x, the curve rises with varying rapidity as indicated by the numerical value of the const. a (acetylpyrrole —58.8, propionyl- and butyryl- —4). For values of y between 60 and 140 min. the relation between the concns. is a const. and the conclusion is that the anesthetic activity of the acetyl-, propionyl-, butyryl- and benzoylpyrrole increases as 1:10:110:250. Referred to cocaine, the activity of the acetyl and propionyl derivs. is less, while that of the butyryl and benzoyl derivs. is 8 times greater. Cocaine and cocaine substitutes (cocaine, stovaine, alypine, novocaine, eucaine B and tutocaine-HCl). The curves for the min. time for these drugs resemble those of the pyrryl ketones. Cocaine gives values corresponding to equation (1), novocaine to $xy = b$, and the others to $y = b/(x - a)$. It was observed that the ratio alypine/cocaine, tutocaine/cocaine, stovaine/cocaine and eucaine/cocaine is const. only for very high values of min. time (150–200 min.) while for novocaine/cocaine it is 60–150 min. For lower values of min. time (10, 30, 60 min.), different numerical values are obtained. Conclusion: The activity of the local anesthetics used, tested by the method described, is less than that of cocaine. For brief intervals of anesthesia, alypine has just slightly less, tutocaine and stovaine has 2/3–3/4, eucaine 1/2 and novocaine 1/20–1/80 the activity of cocaine. PETER MASUCCI

Chloroform narcosis and radon. P. MASCHERPA. *Boll. soc. ital. biol. sper.* **5**, 1167–72(1930).—White mice narcotized with $CHCl_3$ and kept in an atm. rich in Ra emanations showed more rapidly phenomena of excitation and the narcosis intervened more quickly than in the control mice that were also narcotized but kept in ordinary air. Also on awakening, the radioactivated animals required a longer time to reëstablish normal functions than the controls. PETER MASUCCI

Uroselectan in pyelography. JUAN SALLERAS. *Semana méd.* (Buenos Aires) **1931**, I, 570–1.—Uroselectan was given intravenously. In most cases satisfactory results could not be obtained. A. E. MEYER

Irradiated ergosterol in the treatment of tuberculosis. F. MEERSSEMAN AND G. TRICAULT. *Semana méd.* (Buenos Aires) **1931**, I, 595–6.—In 11 human cases, improvement was observed. Tuberculous guinea pigs treated with irradiated ergosterol lived longer than the controls, and the lesions were found to be less severe. A. E. MEYER

The treatment of asthma with sulfarsenol. FÉLIX J. LICEAGA. *Semana méd.* (Buenos Aires) **1931**, I, 636–51.—Clinical cases of successful treatment are reported. A. E. MEYER

Clinical investigations into the effect of intravenous injections of insulin. V. The action of adrenaline on the stomach secretion. KAJ ROHOLM. *Acta med. scand.* **74**, 359–69(1931); cf. *C. A.* **25**, 353.—It was found that injections of insulin stimulate gastric secretion and that this stimulation was really an adrenaline effect. However, adrenaline injections have no effect upon the secretion of the fasting stomach. S. MORGULIS

The effect of colloids on histamine action. BEHREND BEHRENS. *Biochem. Z.* **231**, 92–4(1931).—Small amts. of kaolin or talcum do not affect the action of histamine but large amts. may cause inhibition. S. MORGULIS

The fate of parenterally administered sulfur. R. MEYER-BISCH AND F. TECHNER. *Biochem. Z.* **231**, 110–2(1931).—No changes either in the water content or in the hydrolyzable and total S of the liver have been found in rabbits receiving S parenterally. The changes in S metabolism must therefore be attributed to processes occurring in more peripheral organs, such as cartilage, skin, etc. S. MORGULIS

Influence of insulin on blood and organ lipoids. IRVINE H. PAGE, L. PASTERNAK AND MARIE L. BURT. *Biochem. Z.* **231**, 113–22(1931).—The most pronounced effect of insulin is manifested in the phosphatide content of serum, which diminishes 30%. The cholesterol contents of the blood, kidney and brain are higher than those in the non-insulinized controls. The aliphatic acid contents of brain, blood and serum seem to diminish under insulin, but the I_2 nos. of the acids increase in some (brain, liver) and decreases in other tissues (blood, serum). S. MORGULIS

The relative toxicities of some organic salts of triethyl lead hydroxide. HENRY GILMAN AND O. M. GRUHZIT. *J. Pharmacol.* **41**, 1–4(1931).—The m. l. d. intravenously to rats, and the m. l. d. for the first 3 intramuscularly to rabbits are given for the following: triethyl lead salicylate, triethyl lead phenyl acetate, triethyl lead furoate, triethyl lead *p*-toluenesulfonate, triethyl lead *p*-aminobenzoate, triethyl lead furylacrylate. All the compds. were extremely irritating and produced nervous symptoms. C. RIEGEL

Notes on the importance of exact preparation of tincture of digitalis and on the number of pigeons in the pigeon-emesis method. P. J. HANZLIK, A. B. STOCKTON AND S. S. DAVIS. *J. Pharmacol.* 41, 5–10(1931).—The min. emetic dose (m. em. d.) of digitalis tincture varied with the length of time allowed for extn. of the digitalis leaves. The practicability of using as the m. em. d. that amt. causing emesis in 2 out of 3 pigeons is confirmed by detns. on larger groups. C. RIEGEL

Some clinical actions and therapeutic uses of racemic synephrine. A. B. STOCKTON, P. T. PACE AND M. L. TAINTER. *J. Pharmacol.* 41, 11–20(1931).—Racemic synephrine raised the blood pressure in patients when 0.2 g. intramuscularly or 0.05 g intravenously was given, the rise being from 25 to 30 mm. Hg, and lasting ½ to 1 hr It was ineffective in asthma, and did not prolong the action of procaine in local anes thesia. Applied to the nasal mucous membrane it produced shrinkage of the mucosa without irritation, engorgement or swelling. Solns. of synephrine are stable and could be sterilized by heat. C. RIEGEL

The effect of mechanical constriction of the hepatic veins upon the anticoagulant action of Witte's peptone. ELIZABETH CRANSTON AND O. R. CAILLET. *J. Pharmacol.* 41, 65–70(1931).—Constriction of the hepatic veins previous to injection of the peptone produced a delay in the appearance and a reduction in the intensity of its anticoagulant action, and a less marked reduction in platelet count. C. RIEGEL

Apomorphine tolerance and its relationship to morphine tolerance. FRANK CO TUI. *J. Pharmacol.* 41, 71–82(1931).—Dogs habituated to apomorphine develop a tolerance to its emetic action, but not to its other effects. Dogs tolerant to apomorphine are tolerant to the emetic action of morphine, and vice versa. There is no cross tolerance as regards other effects. Neither morphine- nor apomorphine-tolerant animals are tolerant to the emetic action of pilocarpine. C. RIEGEL

Glycogen storage in the white rat when fed the roots of Arctium lappa. JOHN C. KRANTZ, JR., AND C. JELLEFF CARR. *J. Pharmacol.* 41, 83–7(1931).—Glycogen storage in the liver was increased in rats fed the roots or the carbohydrate prepd. from them, over that in rats fed only on a basal diet of cacao butter. C. RIEGEL

The influence of insulin on the formed blood elements, on the sedimentation rate of the erythrocytes, and on the bleeding and coagulation time. GIULIO LEGA. *Arch farmacol. sper.* 51, 1–23(1930).—In the blood of the diabetic there exists in general a diminution of hemoglobin and red cells, a slight and inconst. increase in leucocytes and bleeding time, and an almost const. increase in coagulation time and sedimentation rate The graver the condition of the diabetic is, the more marked are these changes, though they are not directly related to the degree of glucemia. Dietetic treatment resulting in an improvement of the general condition of the patient causes an increase in erythrocytes and hemoglobin, but it does not influence the leucocyte formula, coagulation time, bleeding time and sedimentation rate. Insulin treatment resulting in a notable improvement of the general condition of the patient has a remarkable influence on the factors under examn., since coagulation time, bleeding time, sedimentation rate and no. of formed blood elements returned rapidly and almost constantly toward physiol. conditions. G. SCHWOCH

The behavior of experimental glucemia in cases of diabetes mellitus treated with insulin. GIULIO LEGA. *Arch. farmacol. sper.* 51, 33–40(1930).—When 20 g. of glucose in 200 cc. water was given to healthy persons, the blood sugar, which was detd. every 30 min. for 3 hrs., rose to a max. during the 1st hr. after ingestion of the glucose. Then it decreased and finally reached values below the normal level. When the same test was carried out in diabetics, the rise in blood sugar was much greater, the values remained at an elevated level for a considerably longer period, the decrease was much slower, and the original level was not reached at the end of the 3rd hr. The grave cases presented the strongest deviations from the normal curve. The more a case improved under insulin treatment, the more closely the glucemic curve approached the normal type. The improvement in the condition of the patient is due to the improved functioning of the pancreas brought about under the influence of insulin. Thus the test described may serve as a method of detg. the functional ability of the pancreas with respect to its internal secretion. G. SCHWOCH

Is codeine without influence on the blood pressure? LUIGI SCREMIN. *Arch. farmacol. sper.* 51, 97–110(1930); cf. *C. A.* 24, 4643.—Intravenous injections of small doses of codeine caused an increase in blood pressure in rabbits and guinea pigs. In the cat the blood pressure was raised by very small doses of codeine; somewhat larger doses, which, however, were still far below the min. convulsive dose, caused a considerable decrease in blood pressure. G. SCHWOCH

The action of photodynamic substances on the carbohydrat metabolism. II.

GABRIELE MONASTERIO. *Arch. farmacol. sper.* **51**, 111–24(1930).—In an earlier study M. had investigated the influence of trypaflavine on the blood sugar of rabbits. In this work its effect on the blood sugar of dogs was studied. Intravenous doses of 5 mg. per kg. were without effect on the blood sugar. Ten mg. caused a pronounced hyperglucemia, while 40 mg. caused hypoglucemia after about 7 hrs. Trypaflavine is quite toxic for dogs, and therefore the 40 mg. dose was given in single doses of 10 mg. each at intervals of 1 hr. This method of subdividing the dose is probably the reason why the hypoglucemia was preceded by a hyperglucemia. The symptoms of hypoglucemia, consisting of generalised tremors and sometimes convulsions disappeared after glucose injection, but the animal remained in poor condition because of the intoxication caused by the trypaflavine. When rabbits injected with 20 mg. trypaflavine per kg. were irradiated by ultra-violet rays the hyperglucemia produced in them was much more intense than when they were kept in the dark after injection of the same dose. Other expts. were concerned with the influence of antiphotodynamic substances injected simultaneously with, or after, the administration of trypaflavine. When small doses of resorcinol totalling about 0.5 g. were injected into dogs, which a few hrs. previously had received sufficiently large doses of trypaflavine, the hyperglucemia developed normally, but the onset of hypoglucemia was greatly retarded. When the resorcinol was injected at the beginning of the expt., the onset of hyperglucemia was retarded. Eosin injected subcutaneously or intravenously did not alter the blood sugar of normal rabbits. The hyperglucemia induced in rabbits by adrenaline or subcutaneous injection of glucose was intensified after eosin administration. On the other hand, the hypoglucemia-producing effect of insulin was attenuated by eosin. Of some other acridine derivs. studied, acridine orange and, to a slight extent, flavicid are capable of producing hyperglucemia. Rivanol was without effect. Inconst. results were obtained with acridine yellow and acridine red. G. SCHWOCH

Changes in the osmotic pressure of the organs after intravenous injection of urea. LUIGI SCREMIN. *Arch. farmacol. sper.* **51**, 129–34(1930); cf. Messini, *C. A.* **24**, 657.—The expts. were carried out on 8 rabbits to which quantities of urea varying from 2.10 to 0.89 g. per kg. were slowly administered by intravenous injection of a 13% soln. The animals were bled to death 90 sec. after the injection was completed and the osmotic pressure of the blood serum and various organs was detd. by the cryoscopic method. In normal rabbits Δ rises in the organs examd. in the following order: serum, brain, muscle, heart, kidney, liver. In the exptl. animals Δ generally increased with increasing doses of urea. For a certain dose, serum always showed the lowest values; slightly higher values were found in the brain, while muscle and liver gave the highest figures. However, the relative increase was greatest in the serum and was smallest in the kidney and liver. The results obtained are discussed in connection with the pathogenesis of uremia, but no definite conclusions are drawn. G. SCHWOCH

Influence of some carbohydrates on the toxicity of potassium cyanide. P. MORETTI AND G. MUSCOLINO. *Arch. farmacol. sper.* **51**, 135–40(1930).—Mixts. of 4% KCN soln. and glucose soln. (10–30%) were allowed to stand at 37° for 24 hrs. When such mixts. in quantities corresponding to 2, 4, and 10 times the m. l. d. of KCN were injected intramuscularly into pigeons, the animals remained alive and well. It is calcd. from the quantities of glucose added that 1 g. KCN is neutralized *in vitro* by 15 g. glucose or less. After a certain period of time the KCN-glucose solns. assume a distinctly ammoniacal odor, however, the reactions of Wortmann and Pagenstecher-Schönbein remain positive. In attempting to hydrolyze the glucose in the glucose-KCN complex a mixt. of KCN and glucose soln. was treated with yeast. After the treatment the mixt. does not reduce Fehling soln., which shows that KCN, after combining with glucose, has lost its antienzymic properties; however, its toxicity was not restored. Similar expts. in which glucose was replaced by other carbohydrates showed that fructose, galactose, mannose and lactose also neutralized KCN, while dextrin, sucrose and gum arabic did not. Starch was only very slightly effective as a neutralizing agent. G. SCHWOCH

The action of yohimbine on the blood pressure and the reversal of the blood-pressure action of adrenaline and adrenalone by yohimbine. MASASHI YAMAUCHI. *Okayama-Igakkai-Zasshi* **40**, 1220; *Chem. Zentr.* 1929, II, 3029.—Small doses of yohimbine cause an increase in blood pressure by exciting the vascular muscle itself. The blood-pressure-reducing effect of larger doses of yohimbine seems to be due to the ability of the poison to render the sympathetic fibers insensitive for the adrenaline, which always circulates in the organism; therefore only the action of adrenaline on the vasodilators becomes manifest, which then surpasses the exciting action of yohimbine on the vascular muscle. By a previous treatment with yohimbine the action of adrenalone is inhibited more strongly than that of adrenaline. G. SCHWOCH

Reversible coagulation in living tissue. I. WILDER D. BANCROFT AND J. E. RUTZLER, JR. *Proc. Natl. Acad. Sci.* 17, 105–11(1931).—Anesthesia and anaphylactic shock are due to the reversible coagulation of protein in certain nerve colloids. Intravenous injection of a 10% NaCNS soln., which peptizes protein, hastens the return of consciousness of rabbits under ether, amytal or morphine anesthesia and prevents death from strychnine or histamine. It prevented anaphylactic shock in rabbits sensitized by subcutaneous injection of egg-white sol. KCNS cannot be used because of its high toxicity. D. S. SEARLE

The influence of insulin and adrenaline on the sugar content of the spinal fluid. J. LUKÁCS. *Magyar Orvosi Archivum* 30, 591–7(1930).—The sugar of the spinal fluid is decreased after the injection of insulin. Decrease in blood sugar sets in sooner than that in spinal fluid. Preceding the decrease in the sugar of the spinal fluid a temporary increase takes place; this is not true for blood sugar. Adrenaline raises the sugar in the spinal fluid and also in the blood; however, the increase in blood sugar takes place first. H. TAUBER

The action of histamine on human blood vessels. J. POGÁNY. *Magyar Orvosi Archivum* 32, 51–6(1931).—0.001–0.002 mg. of histamine intravenously injected into the human vein causes a rise in venous pressure, which sets in immediately after injection but only in veins affected first by adrenaline. 0.01–0.02 mg. histamine also raises venous pressure. The rise sets in after 25–60 sec. and is manifested by accompanied warmth. This can be eliminated if the vein is shut off in the capillary region. H. TAUBER

The action of histamine on human adrenaline sensibility. J. POGÁNY AND G PILAU. *Magyar Orvosi Archivum* 32, 57–61(1931).—The adrenaline sensibility is increased considerably 30–50 min. after subcutaneous injection of small doses (0.005–0.01 mg. per body wt.) of histamine. This effect is attributed partly to the dilatation of peripheric small vessels and partly to the characteristic histamine distribution in the blood. H. TAUBER

Induction of lymphocytosis and lymphatic hyperplasia by means of parenterally administered protein. BRUCE K. WISEMAN. *J. Exptl. Med.* 53, 499–510(1931).—In this study 2 animals received chick "embryonic ext." intraperitoneally, 2 intravenously and 1 subcutaneously; 2 received egg albumin intravenously and 1 subcutaneously; 1 received normal horse serum intravenously and 1 received normal salt intravenously; each injection carried approx. 50 mg. of protein in 66 cc. normal salt soln. The injections caused an increase of lymphocytes in the peripheral blood varying from 23 to 139%. It seems probable that the degree of response is conditioned upon the type of protein used. At autopsy the lymph nodes and spleen showed hyperplastic changes. The thymus did not participate in the hyperplasia. C. J. WEST

I—ZOÖLOGY

R. A. GORTNER

The oxidation-reduction potential in slugs (Agriolimax agrestis). EUGÈNE AUBEL AND ROBERT LÉVY. *Compt. rend. soc. biol.* 105, 358–9(1930).—Oxidation-reduction indicators were injected into living slugs. The oxidation-reduction potential figures for slugs were identical with those formerly obtained for caterpillars. The physiol. r_H in aerobiosis is about 20; in anaerobiosis, it is lowered to a limit between 5 and 6. B. C. BRUNSTETTER

The action of placenta on the metamorphosis and on the development of the smooth muscles in tadpoles. G. GANFINI. *Boll. soc. ital. biol. sper.* 5, 949–53(1930).—The larvae of *Bufo vulgaris* were fed with raw beef, raw and cooked human placenta, aq. ext of placenta and planktons. Raw, cooked or exts. of human placenta contained substances which accelerated the development and metamorphosis of tadpoles and activated the development of the smooth muscles. The amt. of these substances was, however, greatest in the beef. PETER MASUCCI

The importance of arginine-phosphoric acid in the metabolism of the reacting crustacean muscle. EINAR LUNDSGAARD. *Biochem. Z.* 230, 10–8(1931) The metabolism of the reacting crustacean muscle is altered exactly like that of the frog muscle when its lactic acid production is stopped by poisoning with CH_3ICOOH, whereby the arginine-H_3PO_4 of the crustacean muscle behaves just as the creatine-H_3PO_4 of the frog muscle. It is therefore concluded that the hydrolysis of either arginine- or of creatine-H_3PO_4 must be considered as a source of energy. The crustacean muscle is very much less sensitive to CH_3ICO_2H than is frog muscle. S. MORGULIS

Hydrogen-ion concentration in a unicellular body. S. DATE. *Compt. rend. soc.*

biol. **106**, 89–93(1931).—The p_H of the protoplasm of *Amoeba proteus* in the culture (p_H = 8.0) is 6.4 to 7.3 (it is more acid during movement than during repose); the p_H of the nucleus is a little higher than that of the protoplasm. When the exterior p_H varies from 5 to 9, it does not greatly influence the interior p_H. ALBERT L. RAWLINS

A radioactive indicator method for estimating the solubility of acid lead arsenate within the alimentary tract of the silkworm. F. C. CAMPBELL AND CHARLES LUKENS. *J. Econ. Entomol.* **24**, 88–94(1931).—This study describes the use of a radioactive indicator method for the detn. of the amt. of Pb evacuated by the silk worm (*Bombyx mori*) after being fed known dosages of $PbHAsO_4$ and $Pb_4(PbOH)(AsO_4)_3.H_2O$. An arsenate of Th B, a radioactive isotope of Pb, is mixed with known quantities of Pb arsenate. The mixt. is then fed to an insect. The Th B accompanies the Pb wherever it goes in the body and the ratio of Th B to Pb will remain the same as in the original mixt. regardless of the reactions into which the arsenate may enter. The prepn. which was fed to the insect was tested in an electroscope to obtain the quantity of Pb present. The ash of the excrement was similarly tested and from this information the quantity of Pb, and therefore of the Pb arsenate evacuated, was obtained. Results: At least 25% of a moderately lethal dose of $PbHAsO_4$ (0.12 mg. per g. body wt.) passes into soln. within the intestine during the survival period. Basic lead arsenate was much less sol. within the intestine. C. H. RICHARDSON

The catalase content of the Colorado potato beetle during metamorphosis. DAVID E. FINK. *J. Agr. Research* **41**, 691–6(1930).—The variation in the activity of catalase during the metamorphosis of the Colorado potato beetle, beginning with the mature larva, was ascertained by making daily detns. of the quantity of O_2 per g. of tissue evolved from H_2O_2 by the action of catalase during prepupal and pupal development. Analysis of the resulting data indicated a reduction in catalase of 16% on the first day of histolysis and 19% on the second, followed on the third day of histolysis by an increase which, when the pupa was formed, reached the max. of 6% above that of the mature larva. The decline in content of catalase during pupal development was continuous thereafter until a reduction of 51% below that of the mature larva was reached with the formation of the adult. The curves obtained for catalase content and those previously reported for O_2 consumption and excretion of CO_2 (*C. A.* **19**, 2536) were similar for the prepupal period of histolysis. During pupal development, however, the catalase curve declined rapidly whereas the curves for O_2 and CO_2 followed the usual growth curve. W. H. Ross

Phosphorus distribution, sugar and hemoglobin in the blood of fish, eels and turtles. C. M. MCCAY. *J. Biol Chem* **90**, 497–505(1931).—The distribution of P in blood fractionated by Youngburg's method (*C. A.* **25**, 1857) was detd. by a modification of the method of Kuttner and Cohen (*C. A.* **22**, 606); $HClO_4$ was used in place of H_2O_2 for the oxidation. The total P in 100 cc. whole blood of pike is 87 mg., carp 92 mg., bullhead 77 mg., *Chelydra serpentina* 49 mg., compared with beef blood 22.9 mg. Figures for the P distribution, blood sugar and Fe are given. During spawning the hemoglobin and reducing sugar in the blood of lamprey eels decreases while the total P is unchanged. K. V. THIMANN

Physicochemical properties of crocodile blood. D. B. DILL AND H. T. EDWARDS. *J. Biol. Chem.* **90**, 515–30(1931).—The concn. of protein in the serum and of hemoglobin in the blood of crocodiles is lower than in man. The buffer value of the blood is also much less, although that of the serum protein itself is higher than in man. The change in strength of acidity on oxygenating crocodile hemoglobin is twice as great as in human blood, and correspondingly the effect of p_H change on the O_2 affinity is twice as great. The content and distribution of water, Na, K, Ca, Mg, Cl, HCO_3, phosphates, lactate and proteinate in the plasma and cells were also detd. K. V. THIMANN

Effect of inorganic salts on photic orientation in Allolobophora foetida (Sav.). VI. Magnesium sulfate, nitrate and chloride. EKITARO NOMURA AND SHINRYO OHFUCHI. *Science Repts. Tôhoku Imp. Univ.* [4], **5**, 669–89(1930).—A large no. of data are given to show that immersion of the worm in solns. of $MgSO_4$, $MgCl_2$ and $Mg(NO_3)_2$ alters the degree of orientation to light. The forward crawling mechanism in the brain and ventral nerve cord is also affected. The effects are complex. K. V. THIMANN

Effect of light on porphyrin from the integument of the earthworm Allolobophora foetida (Sav.). SATARO KOBAYASHI. *Science Repts. Tôhoku Imp. Univ.* [4], **5**, 763–78 (1930).—The worms were extd. with 20% HCl-alc., centrifuged, the filtrate was neutralized and extd. with Et_2O. The well-washed ext. was treated first with glacial HOAc, then with 20% HCl, re-extd. with EtO_2 each time, washed and evapd., the whole operation being carried out in the dark. A yield of 1.5 g. was obtained from 2 kg. worms. The spectrum of the porphyrin in 20% HCl-alc. slowly fades on illumination, but in 25%

HCl, in alc., AmOH, Et_2O or 6% HOAc-alc., the 4 bands move slightly toward the violet and 2 new bands appear in the red at λ649 and 670μμ. With the appearance of the new bands the intensities of the others decreases. The spectrum agrees approx. with that given by Fischer and Schaumann (*C. A.* **17**, 3349), and is entirely different from that of hematoporphyrin. The changes occur very rapidly and support the view that these pigments of the erythrocytes are photodynamically sensitive. K. V. THIMANN

Analysis of the proteolytic enzymes of Maja squinado by the adsorption method. J. J. MANSOUR-BEK. *Proc. Acad. Sci. Amsterdam* **33**, 858–70(1930).—The ext. of the small intestine contains a protease, carboxypolypeptidase, aminopolypeptidase and dipeptidase. The p_H optimum of the protease of the raw ext. is 6.0 on casein and 6.1 on gelatin, while that of the purified protease is 7.4 and 8.1. The raw ext. is not activated by HCN, H_2S or enterokinase, while the purified ext. is activated by the latter. Separation of the enzymes was achieved by differential adsorption on kaolin and on fuller's earth. The protease was purified by repeated adsorption on $Fe(OH)_3$. J. J. WILLAMAN

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Chemical and physical methods in the examination of food products. EGGERT. *Pharm. Presse, Wiss.-prakt. Heft.* 1931, 20–1.—An address is given which deals with some of the more recent methods. W. O. E.

International agreement for the unification of the presentation of analytical results on foodstuffs for man and animals. ANON. *Ann. fals.* **24**, 69–75(1931).—Final text of the International agreement for the unification of the presentation of analytical results established as a result of the International conference held in Paris on May 13, 1929, by which a unanimous decision was reached. A. PAPINEAU-COUTURE

Determination of water in foods, condiments, etc. B. BLEYER AND W. BRAUN. *Z. anal. Chem.* **83**, 241–68(1931).—Water may be detd. (*a*) by thermic expulsion and weighing the residue, (*b*) by distn. with a high-boiling liquid which is immiscible with water and measuring the vol. of water in the distillate, (*c*) by treatment with CaC_2 and measuring the vol. of C_2H_2 formed and (*d*) by detn. of the dielec. const. These methods are discussed, and a no. of typical food ingredients and food products were examd. comparatively. Conclusion: There is no one method which is always preferable, but preliminary tests will show which particular method is best for a given material. W. T. H.

Biochemical data on wheat harvested at the experiment station of Bordenave. CARLOS ALBIZZATI. *Rev. facultad cienc. quím.* (*Univ. La Plata*) **7**, Pt. 2, 53–7(1930).—Analysis of wheat in the processes of grinding and baking led to the development of an index designated as the "value of utilization." Any wheat having a utilization value of 95 or above is considered suitable. Before discarding a wheat variety because of its low utilization value agronomical and ecological expts. should be made with a view to a possible increase in the utilization value. No conclusions are drawn with regard to bread-making qualities and the diastatic properties of the wheat because of the insufficient no. of expts. performed. B. S. LEVINE

Artificial refrigeration in mill industries and its influence on the quality of flours. S. GÖMÖRY. *Magyar Mérnök Epitészegylet Közlönye* **64**, 387–92(1930).—The heat of the rollers has a bad influence on the chem. and phys. properties of flours. Flours ground on cooled rollers contained about 0.5% more moisture and had their water-absorbing capacities increased by 1–2 cc. for 100 g. of flour. Bread baked from such flours had a somewhat greater vol. and was more homogeneous. The glutenin content of flour did not change, but its quality changed because of its increased moisture content. Intensive refrigeration during rolling prevents evapn. of moisture from wheat, formation of pulpy knots in the flour and eventual fermentation. The flour yield of wheat ground under cooled rollers increased, since peel particles are more easily sepd. from starch and aleuron particles when the moisture content is higher. S. S. DE FINÁLY

Analytical control of imported flours. JOS. KULMAN. *Chem. Listy* **25**, 53–9 (1931).—The methods for analyzing flours suspected of chem. treatment are described. Sp. methods for N oxides, Cl, peroxides, bromates and iodates are given. F. M.

The significance of the acidity in baking. E. ELION AND L. ELION. *Chem. Weekblad* **28**, 103–5(1931).—Twenty-five g. wheat flour extd. with 500 cc. water contg. 50 mg. tartaric acid gave an ext. (I) of p_H 5.9 and with a *diastatic activity* more than twice as high as the diastatic activity of an ext. of the same flour made with water alone (p_H 6.6). Adjusting the p_H of I with alkali to 6.6 did not change the diastatic activity of this ext.

By extn. in the presence of tartaric acid the diastase is apparently either extd. in larger quantity or changes to a more active form. F. DE LEEUW

New method for determining the swelling capacity of bread. L. KARÁCSONYI. *Magyar Chem. Folyóirat* **36**, 59–61(1930).—Detn. with a viscometer is made as follows: Cut up and moisten 10 g. bread crumbs. After 5 min. press through a sieve 10 cm. in diam. covered with Dufour's silk. Dil. the pulp with water to 100 g. with an exactness of 0.01 g. Pour the homogeneous pulp into an Ostwald viscometer (Lüers and Ostwald, *C. A.* **14**, 1167) in a 20° thermostat, mix with an air current and measure the time required for flowing within 0.2 sec. Calc. the av. of 4–5 measurements. The results were well reproducible in the case of wheat breads. Detns. can be made in 30–40 min. as compared with the 24 hrs. of the sedimentation method according to Katz. S. S. DE FINÁLY

The distribution of electrolytes in milk and in the dialyzate. ALESSANDRO ROSSI. *Boll. soc. ital. biol. sper.* **5**, 1060–3(1930); cf. *C. A.* **24**, 5359.—Milk, 20 cc. samples in collodion sacs, was dialyzed against 25 cc. of distd. H_2O. When osmotic equil. was reached, samples from the inside and outside of the sacs were analyzed for Ca, K and P. The results are given in tabular form. Conclusion: the K in the bound form is rather labile and is dependent on the concn. of the diffusible fraction. PETER MASUCCI

Dialysis of milk. I. MICHIO SAITO. *J. Agr. Chem. Soc. Japan* **6**, 1087–92 (1930).—Milk was dialyzed for 5 hrs. The outer soln. was evapd. under diminished pressure. The ppt. thus obtained was a mixt. of phosphates and Ca salts. In the filtrate lactose and lactic acid were found. A substance giving no biuret reaction but giving the ninhydrin reaction was found. Boiled milk was also dialyzed. The dialyzable N substances increased markedly, owing to the production of NH_3 by the heating. Y. KIHARA

Does filtered milk keep longer? K. VAS. *Kisérlet. Közlemények* **32**, 342–55 (1929); *Chimie & industrie* **25**, 453(1931).—Filtration removes the coarser impurities but facilitates the dispersion of bacteria throughout the mass of the liquid, favoring more rapid decompn. of the milk. Of ten samples, in 1 the result was clearly unfavorable; in 3 no difference was noted; in the remaining 6 there was a retardation (up to 11 hrs.) in the rate of coagulation. It would appear that filtration is efficacious only if it is carried out immediately after milking, before the bacteria originally adherent to the larger particles of fecal matter and dirt have become distributed through the milk. A. PAPINEAU-COUTURE

The distribution of phosphorus in cow milk and a scheme for the separation of phosphatides. RINJIRO SASAKI. *Bull. Agr. Chem. Soc. Japan* **6**, 52–61(1930).—Milk powder, dried by the Buflovak drum drier below 70°, was used. The greater part of the phosphatides was more easily sol. in warm alc. or warm acetone than in ether. The existence of much P in the phosphatide fraction has been proved. Y. KIHARA

Commercial sour cream. F. J. DOAN. *Creamery and Milk Plant Monthly* **20**, No. 2, 21–2(1931).—A method of mfg. com. sour cream is given. Before the starter is added, the cream is pasteurized for 30 min. at 180°F. Pasteurization at the high temp. yields a cream which will increase in acidity more rapidly during ripening and which will reach max. viscosity in a shorter time. Homogenization of the cream after pasteurizing is desirable, as the sour cream produced from homogenized cream will be thicker in body and smoother in texture than sour cream produced from unhomogenized cream. Increased body of the sour cream may also be obtained by using cream of higher fat content, by adding solids in the form of plain condensed milk, by the use of gelatin and by the use of rennet. The cream is caused to sour by the addn. of 1–2% of lactic starter. The souring is allowed to proceed at 70°F. until 0.6 to 0.65% acid (as lactic) has developed, whereupon the cream is cooled and bottled. A. H. JOHNSON

The basic viscosity of ice cream mix. J. C. HENING. *Ice Cream Trade J.* **27**, No. 2, 41–5; *J. Dairy Sci.* **14**, 84–92(1931).—Mech. agitation of ice cream mixes reduces their viscosity by a partial splitting of fat clumps. The viscosity of mechanically agitated ice cream mixes may be further reduced by passing them through the homogenizer at low pressures. Different conditions of agitation may vary in their effectiveness in splitting fat clumps and introduce a variable factor in the magnitude of the basic viscosity. The term basic viscosity, as now used for ice cream mixes, denotes a value secured under specified conditions and not a correct min. value from the viewpoint of its being the lowest possible viscosity in the absence of fat clusters. A. H. JOHNSON

Determination of the egg content of egg pastes. O. SZAKACS. *Kisérlet. Közlemények* 32, 459–60(1929); *Chimie & industrie* **25**, 309(1931).—Digest 2 g. of paste with 100 cc. distd. H_2O for 1 hr. shaking at 15-min. intervals; let stand 30 min.; to 70 cc. of clear soln. add 5 cc. of 5% β-naphthosulfonic acid; coagulate on a water bath at 90°, cool

without shaking and centrifuge. The egg content is obtained by comparing the coagulum obtained with that of a blank detn. As the results are very const., a graduated tube may be used instead of comparison with a blank. A. P.-C.

Hawaiian honey. JAR. SVOBODA. *Chem. Listy* **24**, 462–3(1930).—Hawaiian honey imported into Czechoslovakia during 1927 had a powerful aroma and a saline taste. A complete analysis is given. The salty taste was due to a high ash content (0.47–0.88%), in which the NaCl (0.03–0.09%) and KCl (0.19–0.29%) predominated. FRANK MARESH

Note on the manufacture and analysis of chocolates. RAOUL LECOQ. *Ann. fals.* **24**, 11–22, 96–104(1931). See *C. A.* **25**, 153, 1295. A. PAPINEAU-COUTURE

Refrigeration an essential in candy manufacture. TRESPER CLARKE. *Refrigerating Eng.* **20**, 219–22(1930).—C. outlines the manner in which temp. control has been applied to the candy industry. The temp. of the chocolate mix dets. the viscosity of the mix and other properties assocd. with viscosity. The proper rate of cooling of chocolate candy makes it possible to prevent "graying" or dulling. Also the rate of cooling of sugar candies enables one to control the type of crystn. and to obtain the type of crystal desired. Dry rooms are maintained by removing excess moisture from the atm. by cold water or brine circulating in pipes. Maintenance of proper temp. and humidity makes it possible to store candy for 6 months to 1 year without deterioration. A. H. JOHNSON

The disappearance of ozone in cold-storage rooms. ARTHUR W. EWELL. *Refrigerating Eng.* **20**, 358–60(1930).—Under practical conditions the rate of decompn. of O_3 follows the equation for monomolecular reactions. With an initial concn. of 1 part of O_3 per million by vol. the absorption in one-half hr. by the several food products studied was eggs 0.03 p. p. m., fresh apples 0.33 p. p. m., apples previously exposed to O_3 0.06 p. p. m., fresh meat 0.38 p. p. m., meat previously exposed to O_3 0.20 p. p. m. and cauliflower 0.21 p. p. m. A. H. JOHNSON

A new method for the prevention of mold on marmalades, jellies, fruit pastes, etc. RUDOLF RIPA. *Konserven-Ind.* **1931**, 171–3.—After jellification has begun, but before complete cooling, the surface of the product is coated with a thin layer of pectin soln. The pectin soln. dries to a glaze which prevents mold growth. After complete cooling the container is sealed. FRANCIS P. GRIFFITHS

Blue and green molds of oranges. G. B. TINDALE AND S. FISH. *J. Dept. Agr Victoria* **29**, 101–4(1931).—The atm. of the packing shed and the dust on the grader are the important sources of infection of oranges with blue and green molds. Both molds may spread to sound fruit by contact. The optimum temp. for infection with both types of mold is 70–78°F. With shallow inoculations development of the molds is completely controlled by keeping the fruit at 94°F. for 5 days. Oranges, however, will not stand a temp. of 94°F. for more than 4 days without developing a bitter flavor. Storage of the fruit at 94°F. for 3 days, which gives about 90% control of the molds, is recommended. K. D. JACOB

Organic solvents for aiding the removal of spray residue from waxy or oil-covered fruit. R. L. ROBINSON. *J. Econ. Entomol.* **24**, 119–25(1931).—The removal of spray residues from apples which have been sprayed with petroleum oils, or which are covered with an excessive wax formation, is difficult. The addn. of certain org. solvents (alc., $C_6H_6(CH_3)_2CO$, kerosene) to the HCl washing soln. renders removal of the residue most effective. Kerosene appears to be the most practicable for this purpose. C. H. R.

A simple test for sulfur dioxide content of dried apricots. W. R. JEWELL. *J. Dept. Agr. Victoria* **29**, 90–1(1931).—Add 500 cc. of water to 2 oz. of the minced sample contained in a stoppered bottle and shake thoroughly every 10 min. for 2 hrs. Add a teaspoonful of starch soln., prepd. by boiling a teaspoonful of starch with 2 cups of water, and 18 cc. of 0.1 *N* I soln., and shake vigorously for 15 sec. If the dark blue color persists at the end of this period, the sample contains less than 14 grains of SO_2 per lb. of fruit. A gray or apricot color indicates the presence of larger amts. of SO_2. If a green color develops, the test should be repeated with the addn. of a larger amt. of starch soln. The method is designed for rough testing at the packing shed. K. D. JACOB

The supposed relation between the p_H value and acid taste of aqueous solutions, particularly wines. P. CRISCI. *Ann. chim. applicata* **20**, 566–83(1930).—Although there is undoubtedly a relation between the p_H value of a wine and its acid taste, other factors influence this taste markedly, such as sugar, EtOH, glycerol, salts, tannins, etc. The undissocd. org. acid radicals also affect this taste, as the addn. of org. acids affects the acid taste noticeably, while it only affects the p_H value slightly. Dilu. of sour wines with water does not affect the p_H value much, but it greatly changes the taste. A. W. CONTIERI

Refrigeration and the fishing industry (FINN) **13. Treating meal. ERICH STAUDT. Ger. 515,843, May 22, 1926. Foodstuffs, especially meal, is sterilized, matured and bleached by treatment with compds. contg. ClO_2. In the example, wheat or rye flour is treated with gaseous ClO_2 mixed with air and CO_2. The gas is absorbed by the meal.

Improvement of the baking capacity of cereal flours. M. VUK and S. GÖMÖRY. Hung. 101,845, Nov. 12, 1929. A paste-like pulp is formed of the flour with water. This pulp is kept at a temp. higher than that at which albumins coagulate (drying, however, is avoided) until the outlines of starch particles begin to fade under the microscope. Then it is dried at a temp. lower than that of caramelization and is ground to dust. Of this product 4–6% is added to flours to improve them.

Heat treatment of flour. D. W. KENT-JONES, C. W. CHITTY and WOODLANDS, LTD. Brit. 338,603, Aug. 23, 1929. Various details of app. and procedure are described for heating cereal flours for use in ordinary manner or as addns. to untreated flour to improve its properties.

Complex organic peroxides. PILOT LABORATORIES, INC. Brit. 339,336, Aug. 29, 1929. Mixts. of the acid chlorides of higher fatty acids and benzoyl chloride, chlorobenzoyl chloride or bromobenzoyl chloride are treated with peroxidizing agents. Products are obtained suitable for bleaching flour, oil-seed meals, soaps, oils, fats, waxes, egg yolk and other foods products, etc. Acid chlorides derived from the mixed fatty acids of coconut oil may be used as an initial material. Various details of procedure are described.

Bread, etc. JEAN J. PUTSCHER. Fr. 37,165, June 28, 1929. Addn. to 657,741. Petrolatum oil, glycerol and dextrin are added to the cooking salt ordinarily used in the manuf. of bread, etc., dough.

Irradiating bread or other products in baking ovens. ALBERT WÖRNER. U. S. 1,796,134, March 10. A Hg-vapor lamp is mounted in a baking oven with a reflector arranged to deflect the rays from the lamp so that all the irradiation is by reflected rays. This is stated to avoid impairment of taste such as direct irradiation may cause.

Use of pectin in baked food products. ARNOLD S. WAHL (to E. W. Stewart & Co.). U. S. 1,795,980, March 10. In making baked goods such as sweet rolls or cake, pectin is added to a sugar soln. used as an ingredient, in order to improve the texture and yield. The proportion of pectin may be about 5% the wt. of the flour used.

Pectin. ROGER PAUL and ROBERT H. GRANDSEIGNE. Fr. 695,204, Aug. 24, 1929. Neutral pectic juices are caused to solidify slowly to a gel at ordinary temp. by adding 2–10% of com. HCl. The gel. is afterward finely ground and washed free from HCl by water.

Milk preparation free from milk sugar. JACOB POHLMANN and JACOBUS R. F. RASSERS. Ger. 515,894, Sept. 13, 1928. See Brit. 320,497 (*C. A.* **24**, 2512).

Apparatus for pasteurizing milk, etc. FRITZ G. CORNELL, JR. (to Jensen Creamery Machinery Co.). U. S. 1,795,932, March 10. Structural features.

Corrugated heat-exchange shell apparatus suitable for pasteurizing milk EDGAR B. NICHOLS. U. S. 1,797,014, March 17. Structural features.

Tubular heat-exchange apparatus suitable for treating milk, cream, etc. FRITZ G. CORNELL, JR. (to Jensen Creamery Machinery Co.). U. S. 1,795,837, March 10. Structural features.

Apparatus for pasteurizing, aerating and degasifying cream. OLIVER V. JONES and ALVIN SCHNEIDER. U. S. 1,796,951, March 17.

Apparatus for sterilizing milk. RICHARD SELIGMAN. Ger. 518,462, July 10, 1928. See Brit. 302,743 (*C. A.* 23, 4279).

Apparatus for spray desiccation of materials such as milk. FRANK H. DOUTHITT (one-half to Chester E. Gray). U. S. 1,797,055, March 17. Various structural details and details of operation are described. Cf. *C. A.* 24, 4560.

Conserving animal and vegetable matter, especially foods. RICHARD WILLSTÄTTER. Ger. 515,960, Apr. 16, 1929. Addn. to 513,665 (*C. A.* 25, 1921). As in 513,665, HCN is used as the conserving agent. In conserving meat, 20 mg. HCN is packed with each kg. of meat.

Preserving food materials such as fruits, vegetables and meats. U. GIOMI. Brit. 338,768, Dec. 17, 1929. Fruits such as strawberries, peaches, grapes or apricots are immersed in pure alc. and then dried before packing. Vegetables and meats may be packed in vessels and then sterilized with steam, and all such products, placed in suitable receptacles, are subjected to a vacuum treatment, treated with an inert gas and then sealed. App. is described.

Preserving foods such as fish or meats. M. T. ZAROTSCHENZEFF. Brit. 339,172, Feb. 16, 1929. The materials are rapidly chilled or frozen for preservation or transport by subjection to air satd. with a highly atomized liquid such as fresh or sea water or brine in the form of fog and at a low temp. (suitably about —22° to —25°) and may be subsequently defrosted by treatment with a fog-laden atm. at a temp. above freezing. App. and details of procedure are described.

Apparatus for freezing foods such as fish. ALEXANDER H. COOKE (to Atlantic Coast Fisheries Co.). U. S. 1,795,330, March 10. Heat-conducting elements depending from an endless-belt carrier serve as heat-transfer means between the cooling agent and the articles to be frozen. Various structural details are described.

Meat extracts, etc. BEEFEX, LTD., and J. E. APS. Brit. 338,808, Jan. 30, 1930. Cubes of material such as meat exts. are toasted to sterilize them and harden their surfaces so that they can be handled without wrapping. Various details of treatment are described.

Vacuum treatment of corn, fruits, etc. A. E. JONSSON. Brit. 338,635, Sept. 9, 1929. Vegetable products are subjected to a vacuum in the presence of a regulated proportion of water which is vaporized by heating during the continuation of the vacuum treatment (a temp. of 30–45° being suitable for corn).

Apparatus for conditioning raisins or other fruits by dry air treatment. THOMAS W. W. FORREST (to Sun-Maid Raisin Growers of Calif.). U. S. 1,795,302, March 10. Structural features.

Filter press for raisins, etc. PAUL COMBESCURE. Fr. 695,211, Aug. 27, 1929.

Machine for extracting grape juice. KARL MAURER. Ger. 515,925, Aug. 14, 1928.

Cocoa preparations. G. SENFTNER. Brit. 339,034, Sept. 28, 1929. Radioactive chocolate is prepd., *e. g.*, by admix. with sugars which have been dehydrated and then allowed to cryst. in water contg. emanation or radioactive salts.

Coffee preparations. W. PÄFFGEN. Brit. 339,543, Sept. 18, 1929. Caffeine and "roasting toxins" are stated to be removed by use of absorption paper impregnated with finely divided active C.

Stock feed. GAGE A. KENT. U. S. 1,796,031, March 10. Pea- or nut-sized pieces of cracked pressed oil cake are provided with a substantially uniform and continuous coating of sorghum molasses, and each molasses-coated piece is further provided with a final coating of powd. oil-cake meal which prevents adhesion.

Preserving green fodder. SIGMUND VON KAPFF. Ger. 518,463, Oct. 26, 1927. The fodder is sprayed with a soln. contg. HCOONa and a salt or acid capable of liberating HCOOH therefrom.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Good lighting—an executive problem. DEAN M. WARREN. *Ind. Eng. Chem.* 23, 512–6(1931). G. G.

The use of emulsions in industry. V. KUBELKA. *Chem. Listy* 24, 354–7, 372–4 (1930); *cf. C. A.* 24, 5393.—The use of much com. app. for prepg. lab. or theoretical emulsions on a com. scale is discussed. FRANK MARESH

Metafiltration. GEORGES GENIN. *Rev. prod. chim.* **33**, 613–6(1930); cf. *C. A.* **23**, 1186; **24**, 4961.—This method of filtration is described. P. THOMASSET

The injurious action of smoke, dust, gases, factory fumes, etc., on plants. ANTONIN ROLET. *Rev. gén. sci.* **42**, 111–20(1931).—A discussion is given of the origin in the atm. of chem. gases, vapors from tar roads, illuminating gas and other contaminations, and their effect on plants. J. T. SULLIVAN

Heat transfer in superheaters. W. GUMZ AND F. MICHEL. *Feuerungstech.* **18**, 129–34, 152–5(1930). E. I. S.

Measurement of air temperatures. M. TOMLINSON. *Heating, Piping and Air Conditioning* **2**, 769–70(1930). E. I. S.

Predicting the flow of liquids in pipes. R. E. GOULD. *Heating, Piping and Air Conditioning* **2**, 850–2(1930). E. I. S.

Heat transmission to water flowing in pipes. A. E. LAWRENCE AND T. K. SHERWOOD. *Ind. Eng. Chem.* **23**, 301–9(1931).—Expts. indicate that for heating water in turbulent flow the effect of pipe length on the film coeff. of heat transfer is negligible. D. GORDON

Heat transfer through air spaces. P. D. CLOSE. *Heating, Piping and Air Conditioning* **2**, 875–8(1930).—A résumé of important investigations. Brief abstracts are presented. E. I. S.

Calculation of loss of head in straight channels. D. KESTLICHER. *Rev. univ. mines* [8], **3**, 271–91(1930).—A theoretical mathematical discussion leading to the construction of a logarithmic chart for computation of loss of head in rectilinear channels carrying water, oil, steam or air, account being taken of the viscosity of the fluids. E. I. S.

Method for demustardization of one-ton mustard containers. H. P. AVERILL AND F. W. LANE. *Chem. Warfare* **17**, 932–3(1931).—The containers to be demustardized were 2 steel drums which had held mustard for 10 years. For reasons given it was impracticable to use corrosive agents or solvents for mustard to destroy the mustard remaining after emptying the drums. The drums were steamed for a period of 8 hrs. with steam at a pressure of 5–15 lb. per sq. in This destroyed (hydrolyzed) practically all the mustard, only traces remaining in the approx. 75 lb. of residual S. A. L. KIBLER

Refrigerants show similarities. J. E. STARR. *Refrigerating Eng.* **20**, 302–3 (1930).—Similarities between 16 different substances were shown in terms of pressure-temp. and compressor displacement relations. From a knowledge of one point on the pressure-temp. curve it is possible from the curves given to predict the pressure exerted by a gas at any given temp. This was done for CCl_2F_2 and exptl. results agreed fairly well with those predicted from the curves. A. H. JOHNSON

Refrigeration and the fishing industry. D. B. FINN. *Refrigerating Eng.* **20**, 287–90(1930).—Rapid freezing results in the formation of min. ice crystals. Small ice crystals do not rupture the cell walls of the material frozen and therefore when thawed such material more closely resembles the fresh food product than if slow freezing had occurred with consequent formation of large ice crystals. In order not to allow the crystals to grow the storage temp. must not be allowed to fluctuate. Also fluctuations of temp. set up internal pressures which tend to cause oil to ooze from the material frozen. Loss of moisture from frozen material during storage may be reduced by keeping all objects within the storage chamber at as near the same temp. as possible. In such a case moisture will not condense on colder surfaces such as cooling coils, etc. Sufficient insulation so that the temp. differential between the cooled product and the coils is low will prevent serious shrinkage. The occurrence of "rusting," the yellow discoloration which occurs in oily fish during cold storage, may be reduced by using low storage temp. "Rusting" appears to be concerned with a change in the fat or oil, but nitrogenous constituents and possibly H-ion concn. are thought to play an important part. A. H. JOHNSON

Dangerous liquids. B. L. HUBSTIS. *Safety Eng.* **60**, No. 3, 174, 176, 178–9 (1930).—The main considerations in selection of containers for shipment are: strength and tightness, possible reaction of liquid on containers, and proper handling of container, both loaded and empty. E. I. S.

Role of gas masks in mines. P. ESZTÓ. *Bányás. Kohás. Lapok* **63**, 55–60 (1930).—Modern gas masks (respirators), *e. g.*, the "All-Service-Mask" examd. by the U. S. A. Bureau of Mines in May, 1924, yield perfect defense against CO. Therefore gas masks should be used in mines instead of expensive air-regenerating app., as the cost of the former is only 12–15% that of the latter. S. S. DE FINÁLY

The moisture in technical gases. III. Examples. FRIEDRICH LÜTH. *Arch.*

Eisenhüttenw. **4**, 281–7(1930); cf. *C. A.* **25**, 1924.—Numerical examples (10) showing the applications of the method of calcn. are given. J. BALOZIAN

Control and regulation of distilling columns. M. PÉRARD. *Chimie & industrie* **25**, 286–90(1931).—A brief discussion is given, from a practical operating standpoint, of various points regarding the control and regulation of continuous distg. columns, more particularly columns for distg. alc. A. PABINEAU-COUTURE

Vacuum as an insulator. CHARLES O. DUEVEL, JR. *Refrigerating Eng.* **20**, 223–8 (1930).—D. reviews the subject of heat transfer in vacuum insulation and in gases. An app. is described by the use of which it is possible to measure thermal cond. of vacua and gases. A. H. JOHNSON

Separation and size distribution of microscopic particles (ROLLER) **2.**

Hütte. Des Ingenieurs Taschenbuch. Band I. Grundlagen der Technik. Edited by AKADEMISCHEN VEREIN HÜTTE, E. V. Berlin: Wilhelm Ernst & Sohn. 1199 pp. Linen, M. 17.50; leather, M. 20.50.

LEIGH, C. W., AND MANGOLD, J. F.: **Practical Mechanics and Strength of Materials.** 2nd ed. New York: McGraw-Hill Book Co., Inc. 420 pp. $2.75. Reviewed in *J. Western Soc. Eng.* **35**, 495(1930).

Purifying gases. UNION CHIMIQUE BELGE S. A. Fr. 37,418, May 17, 1929. Addn. to 650,516 (*C. A.* **23**, 3284). The pptn. of the $(NH_4)_2SO_4$ is localized in the part of the app. where the NH_3 is dissolved and is prevented in the part where the cooling takes place. The fall of temp. of the satd. soln. is reduced during the cooling but is afterward repeated several times. Cf. *C. A.* **24**, 3843.

Separation of gas mixtures, and nitric acid production. N. CARO and A. R. FRANK. Brit. 338,497, Aug. 13, 1929. A constituent of a gas or vapor mixt. is sepd. by condensation by cooling under such conditions that the mixt. leaving the condenser is unsatd. with respect to the sepd. constituent. Various details of app. and operation are described. Hot aq. nitrous gases, produced by oxidation of NH_3, with addn. of steam, H, O or SO_2 in some cases, can be treated to sep. the water, free from or low in HNO_3, and if desired the N oxides may be directly worked up to form nitrates or nitrites by reaction with suitable oxides, carbonates, chlorides, etc. Sepn. of water, etc., may be effected by the method described in connection with the production of Ca cyanamide, HCN and NH_4 salts or aq. NH_3.

Distilling or drying carbonaceous or other solid materials, etc. E. M. SALERNI and E. M. S. INDUSTRIAL PROCESSES, LTD. Brit. 338,939, July 30, 1929. Operations of this general character or evapn. or other heat treatments of liquids are effected in a described app. which may comprise a plurality of juxtaposed troughs through which the material successively passes while at the same time it is subjected to a secondary movement by the action of agitators in a direction counter to that of main passage of the material.

Alumino-thermic reactions. E. BLÜMMER. Brit. 338,468, March 11, 1930. In effecting reactions such as those of Fe oxide and Al, very high temps. are attained by employing one or both of the reacting materials in molten state. Various details of app. and procedure are described and the operation may be conducted in a vessel surrounded by N under 200 atm. pressure.

Regulating the temperatures of chemical reactions. HOLZVERKOHLUNGS-INDUSTRIE A.-G. Brit. 339,144, Jan. 18, 1929. In regulating temps. such as in the production of acetone from C_3H_7 and water vapor, the reacting constituents are maintained in motion in a continuous circuit past heat-exchanging walls which sep. part of the circuit from a reaction zone, while part of the constituents are diverted continuously into the reaction zone; the reaction temp. is controlled by regulating the speed of travel of the reacting materials in the circuit. App. is described. The procedure is suitable for exothermic or endothermic reactions between liquids or between liquids and gases. Brit. 339,148

relates to similar regulation of reactions carried out under pressures above atm. pressure.

Furnace operation for chemical reactions. Soc. chimique de la Grande Paroisse (Azote et produits chimiques). Brit. 338,444, Jan. 28, 1930. A jet of O or of air enriched with O is impinged on a restricted area of a bed of coke to produce a high temp. zone in which refractory materials such as silica, alumina and Ca phosphate can be volatilized and caused to react. Fine powders are sepd. from the combustion products and in the operation of the process silica or ferric oxide for polishing metals may be reduced to fine powder, and silica or alumina can be caused to react on Ca phosphate for the production of Ca silicate or Ca aluminate and oxides of P. App. is described.

Autolysis or heterolysis of animal or vegetable materials. Soc. française des produits alimentaires azotés. Ger. 518,263, Jan. 14, 1925. The operation is effected with the aid of an antiseptic mixt. comprising $CHCl_3$ and an alc. of lower sp. gr. than the materials under treatment. Thus, fish may be autolyzed with water for 4 days at 40° in the presence of a mixt. of $CHCl_3$ and BuOH.

Granulating salts. I. G. Farbenind. A.-G. (Bodo Haak, inventor). Ger. 518,090, Dec. 14, 1927. In granulating salts, particularly fertilizer salts, by causing the fused salt to fall in drops into a liquid, the path of the salt through the liquid is lengthened by stirring the liquid so that it circulates around the vertical axis of the vessel contg. it.

Gelatinizing organic liquids such as benzine. I. G. Farbenind. A.-G. Brit. 339,360, July 4, 1929. To facilitate safe handling and storage, liquids such as benzine or petroleum ether have formed in them a voluminous "framework" of solid inorg. oxide or hydroxide such as may be produced by the action of a base such as NH_3 on $SnCl_4$, $SiCl_4$ or a chloride of Fe or of Al.

Gel-like benzine. L. Lorber. Hung. 101,509, May 3, 1930. Soap is boiled in alc., then shaken with benzine and water until the mixt. becomes gel-like; *e. g.*, 2 g. soap and 2 g. alc. are boiled, then 500 g. benzine and 2 g. water are gradually added.

Oil or wax emulsion. L. Pócs. Hung. 101,357, Feb. 22, 1930. The aq. phase of the emulsion contains a mol. or a colloidal soln. of halogenated fatty acid soap as emulsifier. A disinfectant agent can be added or the emulsified oil, *e. g.*, turpentine oil, may also have disinfectant qualities.

Oil or wax emulsion. L. Pócs. Hung. 101,358. March 5, 1930. Oil or wax is emulsified with soap, and sufficient alcohol or alcoholic KOH is added to give permanent emulsion in water. Finally the disinfectant is added.

Emulsions, ointments, etc. T. Goldschmidt A.-G. Brit. 339,558, March 9, 1929. Emulsions are prepd. by mixing esters (contg. non-esterified OH groups) of polyhydric alcs. with higher fatty acids, such as glycerol monostearate or diethylene glycol monostearate, with water or aq. solns. in the presence of acylated alkylene diamines or their derivs. such as the C-substituted or N-alkylated derivs., and various other substances may be emulsified or dispersed in the products, such as glycerol, H_3BO_3, citric acid, fats, fatty acids, waxes, vegetable or mineral oils, rubber, glue, gelatin or dextrin, terpenes, perfumes, latex, cow milk, lampblack, talcum or ZnO. Examples are given. Cf. *C. A.* 24, 5437.

Lining liquid containers. Standfasswerke Rostock & Baerlocher and Georg Walter. Austrian 121,533, Oct. 15, 1930. In lining *fermentation vats* and other liquid containers made of concrete or the like with bituminous, resinous or waxy substances the lining substances are applied as aq. emulsions. Preferably, a relatively stable emulsion is first applied, followed by a relatively unstable emulsion. Fibrous materials and other fillers may be included in the emulsions, and the addn. of a small quantity of a hydraulic mortar is advantageous.

Detecting leakage of noxious gases from pipes. Gabriele Windisch. Austrian 121,257, Sept. 15, 1930. The pipes conveying the gases are enclosed in protective pipes, which are connected through a manometer to a suction app. Means for sealing off sections of the protective piping may be provided to assist in locating a leak.

Use of substances of low-boiling point such as carbon dioxide, ammonia or methyl ether for operating engines. Olga, Princess zur Lippe and M. Brand. Brit. 338,894, June 28, 1929.

Use of hydrochloric acid to prepare bore holes for blasting. V. Tschenn. Brit. 338,454, Feb. 11, 1929. Bore holes are provided with spherical enlargements to receive blasting charges by forcing acid such as HCl in fine jets through the nozzle of a described app., and a preliminary charge may be exploded in the bore hole to facilitate the action of the acid.

Drying air surrounding perishable goods during shipment. T. Robbins, F. C.

DEHLER and SILICA GEL, LTD. Brit. 338,855, July 4, 1929. The air supplied to containers in cars, ships, etc., is dried by silica gel or like material. App. is described.

Refrigerating chemicals. N. CARO and A. R. FRANK. Brit. 339,194, Feb. 8, 1929. In processes for absorbing at low temps., liquefying or freezing out N oxides, HNO_3 and their mixts., an aq. NH_3 soln. is used as the "cold-conveying" medium and substances such as NH_4NO_3, metal nitrates and metal thiocyanates may be added to the soln. Various details of concns. of solns. for different temps. are given.

Refrigerator boxes formed of Celotex or the like dipped in asphalt. J. C. STATON (to Coca-Cola Co.). Brit. 338,959–60, Jan. 9, 1929.

Refrigerating apparatus using solid carbon dioxide. W. T. HEDLUND (to Electrolux, Ltd.). Brit. 338,795, Jan. 12, 1929. Structural features.

Refrigerating apparatus utilizing solid carbon dioxide. WALTER S. JOSEPHSON and THOMAS B. SLATE (to Dryice Equipment Corp. and American Patents Development Corp.). U. S. 1,796,907, March 17. U. S. 1,796,908–9–10 (THOMAS B. SLATE to American Patents Development Corp.) also relate to app. for the same general purpose. Cf. *C. A.* **24**, 446, 2517.

Heat-insulating material suitable for building construction. GEORGE B. STRYKER, JR. (to Weatherproof Products Co.). U. S. 1,796,631, March 17. A base of compressed fibrous material such as compressed waste paper and cotton fiber is provided with a top layer consisting of a hardened mixt. of fibrous material with cement, clay and lime. Cf. *C. A.* **25**, 754.

Heat insulators. S. A. I. G. (SOC. ANON. INVENZIONI, GUADAGNIN). Brit. 338,743 Dec. 3, 1929. See Fr. 686,226 (*C. A.* **25**, 549).

Insulating electric wires and cables. FRANCIS J. BRISLEE (to British Insulated Cables, Ltd.). U. S. 1,795,994, March 10. An esterified cellulose compn. such as a cellulose acetate compn. in hard and substantially solvent-free form is applied in layers with textile supports around a conductor under approx. atm. pressure, and the material is then heated to about 100°, at which temp. the compn. softens and flows so that adjacent layers unite and impregnation of the textile supporting material is effected.

Insulation of wire for electrical purposes. I. G. FARBENIND. A.-G. Ger. 518,328, April 24, 1929. The insulation consists of filaments of butadiene hydrocarbon polymerization or condensation products which have been hardened so that they no longer show the extensibility and elasticity of rubber. Hardening may be effected by heat or the action of sulfurizing or oxidizing agents. Examples are given.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Water supply work of the U. S. Public Health Service. ARTHUR P. MILLER *Water Works Eng.* **83**, 907–8(1930).—The relations of the P. H. S. officials with local health agencies, water and sewage treatment plant operators and the like are usually of an advisory character. A review of the manner of certifying water supplies to be used on common carriers engaged in interstate traffic is given. The objectionable practice of adding ice directly to the drinking water used on railway coaches has been nearly eliminated. The effect on the drinking water by careless handling by railway employees is being studied. Since the beginning of the certification of water supplies, the P. H. S. has assumed the entire responsibility of assuring water of good quality on vessels. In 1921 the P. H. S. arranged to do the sanitary engineering work for the National Park Service in the national parks. The work included development of water supplies, building of sewage-treatment plants, mosquito eradication and disposal of combustible and non-combustible waste. C. H. BADGER

Study of a spring in Monferrato (Italy). GIOVANNI CALVI. *Giorn. farm. chim* **79**, 543–8(1930).—A qual. and quant. chem. analysis was carried out on the water of an inexhaustible spring. G. SCHWOCH

New pipe materials for Dresden water mains. SCHEMEL. *Gas u. Wasserfach* **74**, 169–73(1931).—Various types of Fe and steel water mains with and without internal coatings, as well as reënforced concrete and wooden mains, are discussed. R. W. R.

Piping materials for mineral water. E. MAURER. *Gesundh.-Ing.* **53**, 333(1930); *Wasser u. Abwasser* **27**, 369–70.—Most mineral waters in themselves contain no substances corrosive to Fe or other piping. By far the most important agent in corrosion is O_2, introduced from the air. O_2 is not normally present in mineral waters obtained from deep in the earth. CO_2 has little or no corrosive effect. Incrustants will deposit on any

pipe but in less quantity where O_2 is absent. Hence to reduce both corrosion and incrustation, the piping system should be planned to avoid entry of O_2. Wood and galvanized Fe are shortlived while Sn, Pb and Cu pipes are too expensive. Cast-Fe is the best all-around pipe for mineral waters. C. R. FELLERS

Protection of water supply pipe lines system from electrolysis with particular reference to insulation, pipe bonding, electrical drainage and return systems. J. J. LAUDIG, *et al.* *Am. Ry. Eng. Assoc. Proc.* 32, 415–9(1931), *Bull.* 333.—Regular inspections with tests are recommended where electrolysis is suspected and correction is made by insulation or bonding elec. drains where needed. R. C. BARDWELL

Taste and odor troubles in the Minneapolis water supply. F. RAAB. *J. Am. Water Works Assoc.* 23, 430–4(1931).—Certain types of algae, growing in the filters, were the producers of varying and unpleasant tastes and odors. Alum, chlorine and ammonia were tried without effect. Prechlorination, however, was very successful and increased noticeably the filter runs. D. K. FRENCH

Elimination of taste and odor in the water supply of Lancaster, Pennsylvania. EDWARD D. RUTH. *J. Am. Water Works Assoc.* 23, 396–9(1931).—Tastes and odors of various kinds were always present. The filter plant was overloaded. Much of the time the water was not safe to drink. By using anhyd. ammonia and chlorine, almost perfect results were obtained. D. K. FRENCH

Successful superchlorination and dechlorination for medicinal taste of a well supply, Jamaica, N. Y. FRANK E. HALE. *J. Am. Water Works Assoc.* 23, 373–86 (1931).—The water contained Fe and Mn, and the growth of *Crenothrix* was quite noticeable. Treatment with Cl as required produced a medicinal taste. Investigation showed that leaking gasoline, rather than algae, was responsible. After much exptl. work it was found that superchlorination followed by dechlorination gave the best results. SO_2 was used. The method was inexpensive and quickly applied. D. K. FRENCH

Interpretation of water analysis. Equilibrium considerations, determining activities and concentration of ions. D. S. MCKINNEY. *Ind. Eng. Chem., Anal. Ed.* 3, 192–7(1931).—Present methods of detg. the anions of the slightly dissocd. acids (carbonic and phosphoric and their salts) are stoichiometric, and disregard the equilibria which control the relations of these anions and the H and OH ions and hence give the operator a false impression of the quantity of each anion present Further, the results obtained by present methods cannot be evaluated when more than one weak acid is present, unless unwarranted assumptions are made. Derivation and a list of formulas for the calcns. of the fractional activity or activity ratios of various ions obtained from H_2CO_3 and H_3PO_4 at 25° are given. In order to obtain the ion concn. and activities, it is necessary to know the activity coeffs. The relation between the activity and the concns. may be expressed by means of the simplified equation of Debye and Hückel. Methods of application of the equation to actual water analysis are given and explained. WAYNE L. DENMAN

An investigation into the clogging of the filter beds at Topchanchi waterworks during hot weather. B. K. MANDAL. *Indian Med. Gaz.* 66, 84–5(1931).—The growth as well as the actual decay of the lower forms of vegetable life (particularly *Crenothrix*) are the more important factors influencing the clogging of filter beds during hot weather. An increase in temp. with an acceleration in the production of org. matter cause a simultaneous reduction in the dissolved O_2 content, and the evolution of CO_2; these conditions are favorable for the production of the so-called "iron bacterium" and allied forms of life. FREDERICK G. GERMUTH

Chemical control and general supervision of water-treating plants. R. M. STIMMEL, ET AL. *Am. Ry. Eng. Proc.* 32, 419–22(1931), *Bull.* 333.—Survey indicates field inspection is desirable in addn. to lab. check; the field-test method for rapid boiler water analysis recommended in A. R. E. A. Manual is used. Treating plant results should be coordinated with the performance of water in locomotive boilers. R. C. BARDWELL

Treats water twice in new plant. R. V. ZAHM. *Ry. Eng. and Maintenance* 27, 363–4, 377(1931).—The Missouri, Kansas and Texas R. R. installed a complete 30,000 gal. per hr. water-softening plant at its Franklin, Mo., terminal in 1929. Lime, soda ash and Na aluminate are used to soften and clarify a reservoir water ranging from 5.0 to 7.5 gr. per gal. total hardness and 4.0 to 20.0 gr. per gal. suspended matter. Addnl. treatment with alum to neutralize OH and Na hypochlorite for sterilization is given that portion used for drinking purposes with subsequent filtration. A Sparling meter is used for lime and soda ash control. Aluminate is added separately by an automatic dry feeder. A min. settling time of 6.8 hrs. with a max. of 13.8 hrs. clarifies the water satisfactorily. Hardness of treated water averages consistently under 1.5 gr. per gal. R. C. B.

Results of water treatment. T. F. POWERS. *Ry. Age* **90**, 329–31(1930).—In 1911 the Chicago and Northwestern RR. had a leaky flue failure each 58,633 locomotive miles but with supervised water treatment this had been reduced by 1929 to one failure per 4,343,302. Corrosion and pitting still constitute a problem and embrittlement is a potential danger. A properly supervised wayside treating plant has been found a most satisfactory method for correcting water quality. R. C. BARDWELL

Lump or hydrated lime? O. T. REES, *et al.* *Ry. Eng. and Maintenance* **27**, 276–8, 385(1931).—Available CaO for use in water treatment can be obtained in lump lime at as much as 55% lower first cost than in hydrated lime. However, rapid deterioration of lump lime in shipment and storage affects the reliability and where more uniform results and greater accuracy of treatment are required together with greater ease of control, use of hydrated lime is favored. R. C. BARDWELL

Experiments with chlorinated copperas as a coagulant. A. CLINTON DECKER. *Water Works Eng.* **83**, 887–8(1930); cf. *C. A.* **23**, 5525; **24**, 1447, 2818.—The source of supply for the Chickasaw, Ala., filtration plant originates in springs and flows through a heavily cypress wooded territory which imparts to the water a color ranging from 40 to 130 p. p. m. Alky., total hardness and turbidity are low. Color removal was complete when 0.7 grain per gal. of copperas, mixed with 2.16 p. p. m. Cl_2, was added as a coagulant. The Cl_2 added was sufficient to oxidize the Fe and also to satisfy the Cl_2 demand of the raw water. The filtered water is adjusted with lime to a p_H of 7.0–7.2. The increase in color is less when the lime is introduced into the clear-water well than when introduced into the coagulating basin. The length of the filter runs has been increased by this process as compared with alum and lime, thus lessening by 50% or more the wash water required. The cost of chemicals is approx. $10 less per million gal. water. C. H. B.

Clarification of water movement (phenomena). A. REUTHER. *Gesundh.-Ing.* 53, 164–7, 180–5, 194–202(1930); *Wasser u. Abwasser* **27**, 163.—A math. discussion is given with formulas. C. R. FELLERS

Economics of reservoirs. PAUL HANSEN. *Water Works Eng.* **83**, 943–4, 982–6 (1930).—Impounding reservoirs should be formed which will meet the requirements for water during the dryest period likely to occur within the period of anticipated demands. Because of the cost of constructing dams and spillways and the difficulty of bonding new work on dams with old it is not usually economical to provide impounded storage for less than 10 yrs. and often provision for 20 to 30 yrs. is justified. There should be sufficient filtered-water storage to neutralize the differential (for ordinary domestic purposes $^1/_6$ to $^1/_8$ the total day's consumption is usually required) between the uniform rate of filtration and the variable rate of consumption, plus a suitable reserve for fires and that needed for washing filters, less elevated storage on the distribution system. Cost of elevated storage should be balanced against cost of pumping. Steel is considered best for tanks built on towers. At present, 2 million gal. is the max. practicable size for such steel tanks. For the construction of the smaller sizes of exposed reservoirs built on top of the ground steel is cheaper than reënforced concrete. For covered reservoirs steel has a small advantage in first cost with capacities up to 5 million gal. Tables showing the comparative costs of constructing different types of reservoirs are given. C. H. B.

Overcoming algae troubles in a clear-water reservoir. V. BERNARD SIEMS. *Water Works Eng.* **83**, 739–40(1930).—The water supply at Greenville, Pa., is obtained from a stream on which are located 2 reservoirs in series with a sedimentation basin at the lower end. The water then flows to rapid sand gravity filters and Cl_2 is added to the effluent which passes to the clear-water reservoir. Doses of 2 p. p. m. $CuSO_4$ to the clear-water reservoir cut off for several days, followed by doses of 1 p. p. m. $CuSO_4$ to the sedimentation basin, did not satisfactorily prevent algae, especially in hot weather. At present, 1.0 p. p. m. NH_4OH is added between the lime and the alum dosages. The Cl_2 dosage is 1.5 p. p. m. which gives a residual Cl_2 of 0.2–0.3 p. p. m. in the distribution system. Results obtained during 2 months' operation indicate that more Cl_2 can be added without causing tastes and odors, as was formerly the case. This permits a higher factor of safety in sterilization. In addn. Cl_2 is more effective. C. H. B.

Turbidity, plankton and mineral content of Detroit water supply. BERT HUDGINS. *J. Am. Water Works Assoc.* **23**, 435–44(1931).—As a result of the shallowness of Lake St. Clair, the water could readily become turbid and carry plant and animal life. Several types which give the most trouble in water were identified. At the present time little trouble is being experienced and the present plant is considered satisfactory. The natural conditions which are combating the growth of objectionable forms are discussed. D. K. FRENCH

Water softening for small municipalities. C. P. HOOVER. *Am. City* **42**, No. 3, 7 (1930); cf. *C. A.* **23**, 656; **24**, 4106.—Most of the 322 incorporated communities in

Ohio with populations of less than 10,000 use well water for their municipal water supplies. Many such supplies are hard and contain considerable Fe. A hardness of 90 p. p. m. or less seems to be acceptable in this section. High per capita cost together with limited and mediocre technical supervision makes the designing of water-softening plants in small communities difficult. Carbonation has overcome the objections to the taste of softened water and has also made it possible to distribute softened well water without filtration.

C. H. BADGER

Water softening: Some properties of certain base-exchange materials. I. AUSTIN R. MARTIN. *J. Soc. Chem. Ind.* **49**, 389–94T(1930); cf. *C. A.* **24**, 1688.—A discussion is given of the bulk ds. and vol. of interstitial spaces, exchange values at various rates of flow of water, regeneration, mech. disintegration and losses and contamination of water with SiO_2 of Basex, Doucil, Borromite, Kenzelite, Zepholite, Refinite, Natrolith and Nat-Rol. There is greatest exchange value and mech. disintegration in the synthetic material.

O. M. SMITH

Effect of the disposal of water-softening-plant sludge through the sewage-disposal plant. E. F. ELDRIDGE. Mich. Eng. Expt. Sta., *Bull.* **34**, 7 pp.(1931).—Twelve 1500 samples of fresh solids were placed in individual 3-l. bottles which were connected to inverted glass cylinders for gas collection and measurement. Two bottles contained no added softening-plant sludge; 2 were treated with a dry wt. of lime-softening-plant sludge equiv. to 25% of the total solids in the sewage sludge; other samples contained 50, 75, 100 and 150%, resp., of the softening-plant sludge. The total wts. of sewage solids in all of the samples were practically identical at 41.6–42.6 g. Max. gas production, 5.2 l., was obtained from the samples contg. 50% added softening-plant sludge. The optimum p_H for sludge digestion is approx. 7.2–7.6. Excessive amts. of the lime sludge produced an unfavorable p_H for sludge digestion. The expts. are being continued.

C. R. FELLERS

Concentration control of boiler water. HERBERT S. WHITON. *Power Plant Eng.* **35**, 452–4(1931).—Control of concn. is necessary to avoid foaming and steam contamination with impurities, sol. or insol., from the boiler. In certain cases the Baumé hydrometer, especially calibrated, can be used. In others, the titration of chloride as a measure of total concn. is valuable. Cond. methods also have a place. Frequent chem. analyses may be necessary. The concn by-products of various methods of treatment are described. Blowing down the boiler will reduce its concn. and various methods for its regulation are given.

D. K. FRENCH

Relative cost of eliminating impurities in locomotive boiler waters and the value of treatment with respect to chemicals and compounds applied direct to locomotive boilers and roadside tanks, and conditions under which they may be desirable. C. H. KOYL, *et al. Am. Ry. Eng. Assoc. Proc.* **32**, 402–5(1931). *Bull.* 333.—The phys. condition of the sludge formed is important in the successful internal treatment of locomotive boiler waters. Chemicals forming large heavy particles are desirable. A limit of 15 gr. per gal. alkali salts is recommended. Good results can be obtained with soda ash or proprietary compds. under careful supervision, the cost varying with the quality of the water.

R. C. BARDWELL

Boiler-tube corrosion halted by hot-process treatment. R. E. COUGHLAN. *Ry. Age* **89**, 855–6(1930); *Ry. Eng. and Maintenance* **26**, 550(1930).—The Chicago and Northwestern RR. eliminated serious pitting in six 500 h. p. water tube boilers using Chicago city water, by installation in 1928 of a hot-process softener using lime, soda ash and Na aluminate; this replaced unsatisfactory internal treatment. R. C. B.

Experiments and results with boiler-water recycling. FEIGE AND WEISS. *Arch. Warmewirt.* **12**, 16–8(1931).—A rather full account is given of practical expts. on a 1000 h. p. boiler in returning blow-down to the feed water continuously through a 3 mm. orifice. No difficulty was experienced, and the indicated saving was 1500 M. per year.

ERNEST W. THIELE

Water requirements in the textile industry. KEHREN AND STOMMEL. *Z. ges. Textilind.* **32**, 651–3, 676–7, 698–700, 798–800, 811–4, 830–1, 845–7, 860–2(1929); *Wasser u. Abwasser* **27**, 170.—Ground waters and their suitability for use in dye factories, bleaching plants, laundries and creameries are discussed, together with methods of softening, Fe and Mn removal, filtration, Al coagulation and deoxidation.

C. R. FELLERS

Past and present developments in sewage disposal and purification. H. W. CLARK. *Sewage Works J.* **2**, 561–71(1930).—A general discussion touching on all phases of sewage disposal with particular reference to the developments at the Lawrence Expt. Sta.

E. HURWITZ

Review of present sewage-disposal technic. HERMANN BACH. *Vom Wasser* **4**,

160–86(1930); *U. S. Pub. Health Eng. Abstracts* 11, S, 25(Feb. 28, 1931).—A comprehensive review. C. R. FELLERS

Conditions affecting general layout of sewage-treatment works. PAUL HANSEN. *Sewage Works J.* 2, 572–81(1930).—In the design of sewage-treatment works provision must be made for population growths and changes in character of sewage. Each element of the works should be so arranged that future extension can be made contiguously to the initial installation for economy and improved operating control. E. HURWITZ

Operation and control of sewage-treatment plants. CHAS. C. AGAR. *Sewage Works J.* 2, 597–614(1930).—A report of the Division of Sanitation, New York Dept. of Health, contg. suggestions on operation and control of all units which might be embodied in a treatment plant. E. HURWITZ

Laboratory service in sewage treatment. M. STARR NICHOLS. *Sewage Works J.* 2, 591–6(1930).—N. proposed classifying lab. service in 4 divisions: (1) operator's lab., (2) field-control lab., (3) central or state lab. and (4) central or field-research lab. The duties of each division are specified. E. HURWITZ

Sewage filter media and loadings. WM. E. STANLEY. *Sewage Works J.* 2, 486–94 (1930).—See *C. A.* 25, 1928. E. HURWITZ

Chert gravel as sewage filter stone. J. E. LAMAR. *Sewage Works J.* 2, 495–9 (1930).—Natural chert stream gravel gave satisfactory results in that part of the filter more than 3 feet from the surface of the bed. The gravel supported biol. growth and was not materially affected by soln. Chipping at the surface of the bed indicated that under long-continued use it might in time have caused "pooling." E. HURWITZ

Use of domestic sewage purifiers. L. DE FINÁLY. *Technika* 11, 20–6(1930).—A general review is given of different systems, the principles of domestic purifiers based on artificial biol. oxidation methods are discussed; and two newly erected purifiers with activated-sludge treatment are described. S. S. DE FINÁLY

Observations on scum in the Imhoff tanks of the Ruhr District. KARL IMHOFF. *Sewage Works J.* 2, 549–54(1930).—See *C. A.* 25, 369. E. HURWITZ

Effect of gases on growth of bacteria. R. G. UPTON. *Proc. 12th Texas Water Works Short School* 1930, 151–3; *U. S. Pub. Health Eng. Abstracts* 11, S, 23(Feb. 28, 1931); cf. *C. A.* 24, 184.—In order to test the effect of partially vacuumizing Imhoff tanks to remove the gases of decompn., lab. expts. with flasks contg. sewage were partially vacuumized and the effect on bacterial nos. was noted. In general, there was a slight increase in nos. by the agar plate method where the samples were held under 15 in. Hg vacuum. There was no significant difference in the nos. of H_2S formers or anaerobes. Conclusion: The toxic effect of sewer gas on bacteria and other organisms that might aid in decompn. of sewage sludge in the digestion chambers is slight or negligible. C. R. FELLERS

Activated-sludge experiments at the Calumet Sewage Treatment Works. F. W. MOHLMAN AND C. E. WHEELER. *Sewage Works J.* 2, 529–48(1930).—The paddle-wheel-diffused air process of activated sludge shows considerable promise in reducing power requirements. The scheme is readily adaptable to large units and is flexible in that requirements for agitation and for O may be adjusted separately so that the air rate need not be excessive merely to maintain the required degree of agitation. The tests indicated that 10 to 15 h. p. per million g. is sufficient to produce a satisfactory effluent. With the 2-stage process for activated sludge good results were obtained with small quantities of air. However, this process is very sensitive biologically and requires careful control. Bulking of sludge occurred occasionally in the first stage. The sludge produced by the 2nd stage was generally well flocculated and readily settleable. E. HURWITZ

Effect of iron on the anaerobic decomposition of sewage sludge. L. R. SETTER. *Sewage Works J.* 2, 504–20(1930).—Gasification of sewage sludge is not affected by $FeCl_3$ in amounts up to 5 p. p. m. Amounts of $FeCl_3$ from 5 to 20 p. p. m. cause a progressive retardation of gas formation with consequent doubling or tripling of the digestion period. Retardation was partly eliminated by neutralization of the acidity caused by the hydrolysis of $FeCl_3$. Addn. of $FeCl_3$ up to 10 p. p. m. was not toxic to the organisms of sewage sludge; greater amounts showed decided reductions of organisms and amounts as high as 20 p. p. m. completely reduced the microbial population with the exception of the sewage fungi. Iron added as the element, oxide or hydroxide had no appreciable effect on digestion; the acetate, citrate, $FeCl_3$ and $FeSO_4$ caused slight retardation. E. HURWITZ

Rejuvenated sludge. MAX PRÜSS. *Sewage Works J.* 2, 477–85(1930).—Sludge can be rejuvenated by daily vertical mixing of the fresh solids with all the old sludge in a digestion tank. Vertical mixing with the app. described is so thorough that there are

no fresh sludge pockets and fly and odor nuisance due to pumping fresh sludge on to the drying beds is eliminated. Mixing increases the gas yield 100%, reduces the org. content of the sludge, breaks up scum formation and tends to equalize the p_H value and maintain a uniform temp. throughout the tank. E. HURWITZ

Correlation between biochemical oxygen demand and suspended solids of activated-sludge effluent. H. GLADYS SWOPE. *Sewage Works J.* **2**, 500–3(1930).—Results of expts. show that the biochem. O demand of activated-sludge effluents increases with an increase in suspended solids. The relative increase in biochem. O demand is greater as the period of incubation is lengthened. E. HURWITZ

Biological oxidation of sulfur. IV. Influence on ammonification and nitrification in activated sludge. C. V. R. AYYAR. *J. Indian Inst. Sci.* **13A**, 165–71(1930).—Suspensions of sulfur and activated sludge, constantly aerated with ammonia-free air, showed a rapid fall in ammonia during the first 3 days with a corresponding decrease in bacterial numbers. But ammonia was rapidly produced from the 11th to 18th day and large numbers of fungi appeared. After the 10th day, nitrates accumulated steadily until acidity developed to about p_H 5.4. With phosphates present, the active nitrification proceeded longer before being hindered by the acidity. Development of acidity p_H 2.4 reduced the ammonia somewhat in the second 3 weeks. A sudden decrease in ammonia from the 20th to the 22nd day may have been caused by fungus activity. The steady increase in ammonia after the 22nd day may have been due to the colloids, flocculated by the H_2SO_4, leaching out the adsorbed ammonia. With phosphate present, the changes in the second 3 weeks were similar but less intense. M. E. L.

Making and interpreting a sanitary survey. EDWIN C. HURD. *Sewage Works J.* **2**, 582–90(1930).—The manner of making a survey, the elements to be considered, and the method of obtaining desirable information are considered. E. HURWITZ

Recent progress in air conditioning. W. H. CARRIER. *Refrigerating Eng.* **21**, 187–9(1931).—Air conditioning is discussed in relation to the comfort of the individual, fields of application and mech. and engineering requirements. A. H. JOHNSON

Air conditioning on passenger equipment. R. W. WATERFILL. *Ry. Age* **90**, 233–4 (1931).—Air-conditioning equipment being tested in passenger car service, weighing approx. 5 tons, operates by thermostatic control supplemented by hand dampers regulating raw outdoor air. The refrigerating app. uses Carrene (CH_2Cl_2) and Trieline (C_2HCl_3) which are non-inflammable and safe. Practical air conditioning in railway cars is considered to be in the early development stage. R. C. BARDWELL

Soot particles in New York City air. E. E. FREE. *Fuels and Steam Power* (A.S.M.E. Trans.) **53**, 9–12(1931).—Counts were made by an impact dust counter. The more important variable affecting results was the direction of the wind. Another is clumping of the soot particles, the cause of which has not been detd. An av. of approx. a half-million dust and soot particles is to be found in each cu. ft. of N. Y. City air. At least 90% is ordinary soot or unburned C. The following were also found: auto, tire rubber, asphalt, brick, rock, org. materials, slivers of glass, glazed tile, leather, cotton fiber, hair and a few living mold spores. The size varies from 0.0001 to 0.0500 in. At 100 ft. above the street level the no. of soot particles decreases 25 to 50% at 5th Avenue and 23rd St.; no high level counts were made at other points. For the air over the entire city the av. amt. of suspended matter is 4 to 5 short tons. The relative absence of ash indicates that most of the city's soot and air dust comes from small fires in apartment houses, office buildings and homes, rather than from smoke stacks of the large power houses or other industrial plants. H. C. PARISH

Investigation of atmospheric pollution—report of superintendent of observations. J. S. OWENS, *et al. Dept. Sci. Ind. Research 16th Rept.* 1931, 7–26.—The rept. contains a list of stations, results obtained with the deposit gage, results obtained with the automatic filter, measurement of daylight and deposit of microörganisms at Stockport. Tables show the mean monthly deposits recorded in 1929–30, classification of mean monthly deposits recorded in 1929–30, expressed as % of the general av. for the respective stations and hourly variations of suspended impurity, in different seasons. Eighty-four stations have deposit gages and 11 have automatic filters. No conclusions are drawn. W. H. BOYNTON

Stream pollution from the operator's point of view. EARLE B. PHELPS. *Sewage Works J.* **2**, 555–60(1930).—There are 3 types of stream pollution with which the operator of a sewage plant has to contend, namely, phys., chem. and bacteriol. Sewage-treatment works are designed to deal with each of these types independently or as a whole depending on the capacity and limitation of the stream into which the effluent is to be discharged and on the uses to which the stream is to be put. A knowledge of conditions down-stream facilitates the intelligent operation of the plant. E. H.

Importance of the vacuum system of sludge removal and septic-tank cleaning. A. RINGEL. *Gesundh.-Ing.* 1930, 308–14; *Wasser u. Abwasser* 27, 176.—The advantages of the method are outlined. C. R. FELLERS

Removal of ordinary sewer gases. A. SALMONY-KARSTEN. *Wasser u. Gas* 1930, 785–7; *Wasser u. Abwasser* 27, 177; cf. *C. A.* 25, 1313.—A patented app. is described. C. R. FELLERS

Packing-plant waste treatment. M. STARR NICHOLS AND JOHN C. MACKIN. *Sewage Works J.* 2, 435–42(1930).—Treatment of packing-house waste by plain sedimentation and sprinkling filter resulted in 90% purification based on removal of suspended solids, org. N and fats and about 80% based on reduction in biochem. O demand E. HURWITZ

Use of sewage gas as city gas (FULWEILER) 21. Leather, sanitation and colloid chemistry (WILSON) 29. Mottled enamel (MCKAY) 11G. Filter [for water] (Ger. pat. 515,852) 1.

PLANCHON, RENÉ: **Traitement industriel et rationnel des sous-produits d'abattoires et des déchets organiques.** Paris: Dunod. 460 pp. F. 140; bound, F. 150.

Filter suitable for filtering water through sand. STANISLAUS J. RICKS and CHARLES E. DOUGLAS. U. S. 1,796,960, March 17. Structural features.

Apparatus for softening water with base-exchange materials. S. A. KRÜGER. Brit. 339,510, Dec. 21, 1929. Structural features.

Transportable plant for sterilizing water by chlorination. JOSEF MUCHKA. Austrian 121,020, Aug. 15, 1930.

Apparatus for addition of corrosion-preventive chemicals to water in hot-water systems. HENRY L. SHULDENER. U. S. 1,796,407, March 17. Structural features.

Electric system for protecting boilers. ALEXANDER KIRKALDY (to Electro Anti-Corrosion Corp.). U. S. 1,796,715, March 17.

Device for degasing boiler-plant water. MASCHINENFABRIK OERLIKON Ger. 515,597, Mar. 27, 1928.

Boiler-scale remover. Z. V. PIVNEV and S. N. IGNATCHENKO. Russ. appl. 44,852, Apr. 12, 1929. A mixt. of K_2CO_3 and $CuSO_4$ is placed in the boiler. The mixt. is then removed with water together with the scale after a certain period.

Use of sodium aluminate to increase the rate of anaerobic digestion of sewage solids. WILLEM RUDOLFS (to National Aluminate Corp.). U. S. 1,797,157, March 17.

Rotary sewage distributor. E. HARTLEY. Brit. 338,650, Sept. 20, 1929. Structural features.

Aeration tank (with a power-driven agitator) for sewage treatment by activated sludge. KARL IMHOFF, FRANZ FRIES and FRIEDRICH SIERP (Fries and Sierp to Imhoff) U. S. 1,797,147, March 17. Structural features.

Apparatus for incinerating garbage, etc. ALEXANDER A. GOLOVTCHIKOV (one-half to Shun Ichi Ono). U. S. 1,795,771, March 10. Structural features.

Apparatus for clarifying waste waters of the paper, cellulose, etc., industries. ERNST BUCHHAAS. Ger. 518,063, June 5, 1928. See Austrian 114,184 (*C. A.* 24, 189).

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER AND M. S. ANDERSON

Method and procedure of soil analysis used in the Division of Soil Chemistry and Physics. W. O. ROBINSON. U. S. Dept. Agr., *Circ.* 139, 1–19(1930).—The fusion method of soil analysis developed for use in the soil chemistry lab. of the Bureau of Chemistry and Soils is described. Directions are given for the prepn. of the soil sample after it reaches the lab. The limits of error allowable in a satisfactory analysis are discussed, and the limits of error for various elements are given in percentages and in lbs. per acre. Methods and procedures are given for the detns. of moisture, loss on ignition, org. matter, Cl, F and the oxides of Si, Ti, Al, Fe, Mn, Ca, Mg, K, Na, P and S. The method is designed to show accurately the ultimate comp. of the soil for scientific purposes, but it is claimed to have only a very general application to problems involved in soil fertility studies. W. H. Ross

The study of the dynamics of the absorbing complex of soils. M. A. VINOKUROV. *Pochvovedenie* (Pedology) 23, No. 3–4, 46–92 (in English 92–3)(1928).—In a series of

expts. on the A and B horizons of a chernozem soil the amt. of exchangeable Ca and Mg, exchange capacity and unsatn. were detd. during the vegetation period on different systems of cropping, and during the various seasons. It was noted that the Ca was higher in the fall and lower in the spring. The reverse is true for Mg. The total bases was lower in the spring. The base-exchange capacity as detd. by the $BaCl_2$ method showed some variations. During the first part of the growing season the total exchange capacity decreased slightly, whereas the Ca increased. In the spring the soil was found to be slightly unsatd. In the B horizon the unsatn. was greater in the spring, and in A it was greater in the fall. In some cases, especially on the soils in sod the total Ca and Mg absorbed was greater than the base-exchange capacity. The suggestion is made to consider the absorption capacity as detd. by the Ba method as the exchange or true absorption capacity. The increase in absorption capacity is also to be considered as absorption capacity, but the cations are not exchangeable. During the summer and winter seasons there is an increase in absorption capacity. Vinokurov ascribes this increase to the changes in p_H and perhaps mech. absorption. The quantity of highly dispersed particles of the absorption complex drops beginning with the spring season up toward the middle of summer. It is due to the state of satn. of the complex; it is more unsatd. in the spring. J. S. JOFFE

Experiences with the Neubauer method for determining mineral nutrient deficiencies in soils. S. F. THORNTON. *J. Am. Soc. Agron.* **23**, 195–208(1931).—Comparisons are made of the 0.2 *N* HNO_3 extn., Neubauer method, Illinois phosphate test, Hoffer stalk test, pot tests and field yields on 6 soil series. The Neubauer method gives results which agree most closely with those of pot and field tests. The 0.2 *N* HNO_3 extn. and Illinois phosphate tests give extremely high P_2O_5 results for all soils having received applications of phosphate rock and for soils of the Culver sand series regardless of previous fertilization. The Neubauer method sets as tentative limits for deficiencies for field crops under Indiana farming conditions 4 mg. P_2O_5 and 10 mg. K_2O. Nutrient absorption by seedlings is greatly affected by the selection of seed and temp. control and in a minor way by light intensity, moisture content, soil reaction and the presence of other nutrients. J. R. ADAMS

A method of oxidizing and dissolving soil for the determination of total and filtrable manganese and phosphorus. E. M. EMMERT. *Soil Science* **31**, 175–82(1931).—Soils are prepd. for total Mn and P analyses by the use of H_2SO_4 and $NaClO_3$ to destroy org. matter and to bring minerals into soln. One g. of soil is placed in a Kjeldahl flask, 2 g. $NaClO_3$ added, then 25 cc. of 50%, (by vol.) H_2SO_4, and the flask is gently heated. If the acid concn. is correct and the heat applied properly, ClO_2 will not accumulate in sufficient quantity to cause an explosion. P detd. in solns. prepd. in this way is greater than when the $Mg(NO_3)_2$ method is used. A method for detg. available Mn and P consists of shaking 200 g. of soil with 400 cc. of H_2O, filtering through a Whatman No. 2 filter paper and making detns. in the filtrate, which may contain some colloidal material. It is assumed that the soln. contains the approx. amt. of Mg and P present in available form. M. S. ANDERSON

Profile studies in the western province with reference to hardpan formation. M. S. DU TOIT AND J. REYNEKE. *South African J. Sci.* **27**, 280–95(1930).—Complete chem. analyses are given for soils of 3 profiles. There appear to be 2 extreme modes of hardpan formation: one involves accumulations of SiO_2 under arid alk. conditions and in some cases subsequent dehydration and building up of complex silicates, while the other mode consists of accumulation of sesquioxides and in some cases humus or both. Later desiccation of this may result in the formation of Fe_2O_3 concretions and Fe_2O_3-cemented sand grains. Between these 2 extremes there may exist a great variety of pans of varying degrees of intensity. A study of the behavior of $Fe(OH)_3$ and $Al(OH)_3$ in the presence of SO_4 and Cl ions indicates the possibility of a sol. state beyond the point of complete coagulation. M. S. ANDERSON

The potash requirement of South African soils. I. DE V. MALHERBE AND M. H. SLABBER. *South African J. Sci.* **27**, 236–52(1930).—Analytical data are given for a large no. of South African soils. The detns. made include mech. analyses, p_H, K_2O sol. in strong HCl and in citric acid, K_2O by the Neubauer seedling method, and Al_2O_3 sol. in HCl. The soils are, for the most part deficient in K_2O. Fertilization with K_2O prevents leaf scorch on certain varieties of fruit trees and berry fruits under arid conditions and increases the quality of the fruit and its keeping qualities. Fairly const. ratios exist between K_2O dissolved in concd. HCl, citrate-sol. K_2O, and K_2O by the Neubauer method. Approx. crit. values of these several ratios are proposed for these soils when grain crops are grown. The sandy soils are particularly deficient in K_2O, and frequent applications involving relatively large quantities of K_2O are required for

markedly increasing the quality of fruit and for preventing leaf scorch under the arid conditions prevailing. M. S. ANDERSON

The nature of soil acidity as affected by the SiO_2-sesquioxide ratio. L. D. BAVER AND G. D. SCARSETH. *Soil Science* 31, 159–73(1931).—A study is made of the colloidal material from 21 different soils representing various kinds and states of weathering. The SiO_2-sesquioxide ratio, the total base-exchange capacity, and certain characteristics of the nature of the soil acids have been detd. on each of these colloids. The nature of the soil acids varies considerably in different soils. In weathered soils the nature of the acids is solely a function of the kind and extent of weathering and is independent of the parent material. This indicates that there is more than 1 type of soil acid. Colloidal material of high SiO_2-sesquioxide ratio extd. from well-weathered soils tends to be more highly buffered and to exhibit stronger acidity than colloids having a low ratio. Total exchange capacity is also higher. The nature of the soil acids may prove a valuable criterion in the classification of soils. Buffer capacity of the colloids appears to be primarily a function of the nature of the soil acid. The exchange complex may develop by removal of certain constituents from the original aluminosilicate minerals; by mutual flocculation of colloidal oxides of Al, Fe and Si; and by pptn. of Al, Fe and Si from soln. There is no one direct relationship between SiO_2-sesquioxide ratio and the total exchange capacity of the colloid, or the nature of the soil acid. Free oxides of Al, Fe and Si may be present in colloids, and it is suggested that it might be desirable to eliminate these when considering the relation of the compn. of colloidal material to physicochem. properties. M. S. ANDERSON

The development of roots related to the calcium content of soils. JOH. GÖRBING. *Zuckerrübenbau* 12, 125(1930); *Listy Cukrovar* 49, No. 12, Rozhledy 9; Cf. *C. A.* 25, 553.—The growth of fine roots was studied in soils of various p_H values; the greens were normal in soils in which the roots were stunted. In the more acid strata, the roots became stunted regardless of the depth of stratum in which they were planted. In neutral or alk. strata, a luxurious development of roots occurred. FRANK MARESH

The influence of drying the soil on the microbiological processes in the soil. V. K ZALESSKII AND A. M. KUKHARKOVA. *Pochvovedenie* (Pedology) 23, Nos. 3–4, 94–111 (in German 111–2)(1928).—Drying the soil increased the soly. of org. matter, the amt. of available N and P compds. Peptone added to dried soil upon wetting did not increase the activity of the flora, whereas mannitol and glucose did. Drying the soil decreases the absorption power of the soil for microbes; hence there is a greater activity providing available org. matter is furnished. The addn. of carbohydrates to a dried soil stimulates the activity of the microörganisms, and they use the available N and P. The disappearance of nitrates from the soil is due primarily to the absorption by plants and microörganisms. J. S. JOFFE

The fungus flora of the soil. H. L. JENSEN. *Soil Science* 31, 123–58(1931); cf. *C. A.* 25, 1934.—A study of the fungus flora of 100 Danish soils of reactions varying from p_H 3.34 to 8.35 shows the largest amt. of mycelium in acid soils rich in org. matter. There is no clear relationship between no. of fungi and soil type or soil reaction except that very heavy clay soils are relatively low in fungi. The addn. of lime does not markedly depress fungi, but greatly stimulates bacteria and actinomyces. Some fungi will grow in soil made as acid as p_H 1.5, while others are checked at p_H 3.7 to 4.2. M. S. ANDERSON

Soil bacteria. II. YOSHIHIKO YAMAMOTO. *J. Agr. Chem. Soc. Japan* 6, 873–83 (1930).—Mucors are classified into 2 groups: (1) monomucors (sporangiophores not branched) and (2) polymucors (sporangiophores branched). The list of soil Mucorales was mentioned. Y. KIHARA

Reducing the consumption of sulfuric acid in reworking of phosphorite of Izyum. M. A. EGOROV. *Ukrainskii Khem. Zhur.* 5, No. 2, Tech. Pt. 43–63(1930).—Agricultural expts. have shown that a certain part of Ca contained in the phosphorite of Izyum (I) possesses unusal mobility and acts as a very strong retrograding agent on the phosphoric acid (II) in I, rendering it sparingly sol. and thus only slightly available for plant vegetation. Instead of the costly process of removing Ca from I (Rozhdestvenskii, *C. A.* 22, 2022) the present investigation gives methods of chemically binding Ca, whereby its deleterious action on the mobility of II in I may be entirely eliminated. Conclusions: The activation of II in I by citric acid (III) is greatly increased with the addn. of oxalic acid (IV), KCl and NaCl. The activation of II by IV is increased with NaCl. Under some conditions IV *per se* can entirely remove II from I. The activity of H_2SO_4 on I is greatly increased by addn. of alkali oxalates (which is not the case with phosphorites of other origins), whereby the entire II in I may be rendered H_2O-sol. and the consumption of H_2SO_4 may be reduced about 2.5 times. With the aid of a

little H_2SO_4 and some $(COONa)_2$ a phosphate was prepd. which produced in 1929, with cultivation of sugar beets, results equal to those of superphosphate, the prepn. of which consumes 3 times as much H_2SO_4. The work is being continued. CHAS. BLANC

The electrodialysis of phosphorite of Izyum. K. N. TARANOV. *Ukrainskii Khem. Zhur.* 5, No. 2, Tech. pt. 65–75(1930); cf. *C. A.* 23, 460.—The investigation has been undertaken for the reworking of low-grade phosphorite (I) of Izyum by electrodialysis, whereby its P_2O_5 may become available for plant vegetation. Conclusions: By the electrodialysis method it is possible completely to decompose I and sep. all of the P_2O_5 and Ca in the form of aq. solns. The residue of I has an acid reaction (AcONa). By the double-chamber process of sepn. of P_2O_5 from I, there are formed residua of I, which proved as effective as superphosphates in vegetative expts. (oats). The enrichment of residua with P_2O_5 is due to the removal of some components, such as Ca, CO_2, Cl, etc. By the electrodialysis method only H_2O and the elec. current are required. Questions pertaining to such factors as tension and strength of the current, the relation between the electrode surface and the mass of I, etc., have not yet been studied. CHAS. BLANC

Experiments on the production of thermophosphates from the Khibinsk apatite. S. I. VOLFKOVICH AND S. S. PERELMAN. *Udobrenie i Urozhai* (*Fertilizers and Crops*) 2, 570–80(1930).—By a flotation method a product was obtained from the Khibinsk apatite with a 40.5% P_2O_5 content. This and 2 other samples contg. 27.12 and 19.47% P_2O_5 were fused with Na_2CO_3. By using 30.2 parts of the 40.5% P_2O_5 sample for 100 parts of the phosphate at 900–1200° a product was obtained with a 70% coeff. of decompn., the latter representing the ratio of citrate-sol. P_2O_5 to the total. With a 25% excess of Na_2CO_3 the coeff. increases irrespective of the temp. from 900° to 1200°. With a 50% increase the proportionality between the Na_2CO_3 and increase in P_2O_5 disappears. At 1100° the coeff. drops from 75.3 to 60.7% and then again increases at 1200° to 92.6%. At 1300° the mixt. fuses, but there is no increase in P_2O_5. The optimum conditions were found to be at 1200° with 1.5 times the amt. of soda used originally, *i. e.*, 45 parts of Na_2CO_3 to 100 parts of apatite. With the 27.1% P_2O_5 sample at 1000–1200° with 20 parts of Na_2CO_3 to 100 parts of phosphate the coeff. of decompn. was 70–80%. A 25% increase of Na_2CO_3 increased the coeff. of decompn. almost to 100%. Even at 900° such a mixt. gave an 82.2% coeff. With the 19.5% P_2O_5 sample at 1200° with 22 parts of Na_2CO_3 to 100 parts of the phosphate almost 100% of the phosphate became citrate sol. Addns. of 10% SiO_2 to the mixt slightly increased the coeff. of decompn. SiO_2 alone had no effect. An increase of the SiO_2 to 20% produced neg. results. Addns. of $CaCO_3$ alone had no effect, but with the Na_2CO_3 an increase in the coeff. took place. The time factor of heating the mixt. brought out the fact that 30 min. gives the optimum. The cooling of the mix immediately after 30 min. heating increased the soly. of the product. Heating with various chlorides gave neg. results. With Na_2SO_4 and charcoal a product was obtained with a coeff. of 80%. Vegetation expts. with thermophosphates show that it is just as good as Thomas slag, but it is slightly inferior to superphosphate. J. S. JOFFE

The relation between the geological origin and the available phosphoric acid of a soil. L. NEUBERGER. *Kunstdünger u. Leim* 28, 77–8(1931).—Review. C. J. S.

A colorimetric determination of phosphoric acid in soils. A. NĚMEC, LANÍK AND KOPPOVÁ. *Vestník svazu výzkumných ústavu zemedelskcýh* 5, 18(1930); *Listy Cukrovar* 49, No. 4, Rozhledy 2.—The Konig-Lemmermann method requires a long time for analysis, and soils high in Ca make the ignition of citrate salts very difficult. For routine work the method is: shake 10 g. of soil with 100 cc. of a 1% citric acid soln. (soils high in Ca have to have a correction factor) for 1 hr. Repeat the process for 1 hr. on a subsequent day. Filter or centrifuge, treat 5 cc. of the clear soln. with 10 cc. of 40% H_2SO_4, bring to a boil, and treat with 0.1 *N* $KMnO_4$ until a faint but permanent pink color remains. Remove any excess of $KMnO_4$ with H_2O_2. Digest the soln. on a water bath for 30 min., drain into a 100-cc. vol. flask, treat with 4 drops of α-dinitrophenol, and neutralize with 15% NH_4OH. Cool the soln. and treat with 2 cc. molybdic acid and 0.3 cc. $SnCl_2$. This produces a blue color; make up the soln. to 100 cc. and compare colorimetrically. The standard soln. is made from K_2HPO_4 contg. 0.05–0.5 P_2O_5 per 10 cc. The values run higher than those with the K.-L. method; N. ascribes this to a more thorough extn. FRANK MARESH

The use of the Neubauer method for determining phosphoric acid supplies in soils. A. NĚMEC. *Zemedelský arch.* No. 3, 129(1930); *Listy Cukrovar* 48, No. 52, Rozhledy 11.—The Neubauer method of sprouting plants yielded low P_2O_5 values in soils which were adequately supplied according to fertilizer tests. The cause of a lowered resorption of P was found to be due to a low N content. All soils had a low N and low nitrifica-

tion power. The Neubauer method does not take into consideration the laws of minima. Fertilizing with N increased the resorption of P in which low Neubauer values were obtained. FRANK MARRSH

Efficiencies of phosphoric acid of various fertilizers for spring- and autumn-sown barley. IWAO OMAI. *Ann. Agr. Expt. Sta. Government-General of Chosen* **3**, 394–402 (1930).—Application of Na_2HPO_4, bone meal and superphosphate gave about 190% greater yield and 130–140% more of absorbed P_2O_5; rice polish and $AlPO_4$ gave 150% greater yield and 60–70% more absorbed P_2O_5 than when no P_2O_5 was applied. In general autumn-sown barley showed higher absorption and higher yield than spring-sown barley. Tests for residual P_2O_5 after the first crop showed great value for the second crop. K. KISUTA

A contribution to the evaluation of requirements for fertilizing soils with phosphorus. A. NĚMEC. *Vestník Ústř. Jednoty Repařo Csl* **11**, 277(1930); *Listy Cukrovar* **49**, No. 4, Rozhledy 1.—The use of P_2O_5 in fertilization is closely allied with Ca; soils with adequate Ca should have more available P_2O_5 than soils deficient in Ca. Other elements controlling the availability of P_2O_5 are Fe and Al; soils contg. more than 50 mg. Fe freely sol. in 1% citric acid fail to respond to P_2O_5 treatments, even though they show a P_2O_5 deficiency by the König-Lemmermann method. The method for detg. the available P by evaluating only the P_2O_5 sol. in H_2O becomes of no value for soils contg. less than 3 mg P_2O_5 (sol.) per 1 kg. soil. Soils contg. large quantities of Fe did not react to P_2O_5 fertilizations, even though the sol. P_2O_5 was high or low. All available methods were inadequate to det. what soils would respond to P_2O_5 treatments. Soils deficient in both Fe and P_2O_5 gave increasing yields of beets; N. attributes this to SiO_2, for only soils contg. less than 12 mg. sol. SiO_2 per 1 kg. of soil reacted to H_3PO_4 treatments regardless of whether the P_2O_5 was high or low. In soils with a high Fe content, P_2O_5 fertilizers fail to increase the yield of beets, even though the sol. SiO_2 may be less than 12 mg. per kg. of soil. FRANK MARESH

The retrograding action on phosphates of the soil under various conditions. F. V. TRIFONOV. *Ukrainskii Khem. Zhur.* **5**, No. 2, Tech. pt. 77–91(1930).—The influence of moisture on the retrogradation of phosphates is considerable. Thus the soly. in H_2O of $CaHPO_4$ decreases by 30% with an increase of 30–100% in the moisture based on the total moisture capacity of the soil. The soly. of Izyum phosphate in citric acid increases to 65% with an increase in moisture. The highest amt. in soln. was observed at a moisture content of 80–100% of the total moisture capacity. The influence of temp. on the retrogradation is different for different phosphates; *e. g.*, temp. changes do not affect solns. of Izyum phosphorite in H_2O or in citric acid, while increase in temp. greatly decreases the soly. of $CaHPO_4$ in both water and citric acid. The retrograding action on phosphates of soils of the region of forest steppe varies greatly; there is a regular decrease of retrogradation with declining richness of the soil. CHAS. BLANC

The constitution and citrate solubility of tricalcium phosphate and of phosphate rock. K. D. JACOB. *Phosphorus Digest* (April, 1931), pp. 7–9; cf. *C. A.* **25**, 1619.—When 0.5-g. samples are used, 65–75% of the total P_2O_5 in pptd. $Ca_3(PO_4)_2$ and in steamed bone meal is sol. in neutral NH_4 citrate soln., but when the wt. of the sample is increased to 2.0 g., only 25–30% of the total P_2O_5 goes into soln. The citrate soly of ground phosphate rock is only about 12% of that of $Ca_3(PO_4)_2$ and bone. The low soly. of phosphate rock seems to be due principally to the fact that the phosphate is combined with F to form a complex Ca fluophosphate of the same type as cryst. fluorapatite. K. D. JACOB

Can superphosphate and its components increase the solubility of soil potash? C. DREYSPRING AND K. BRINKMANN. *Superphosphate* **4**, 69–75(1931); cf. Dreyspring and Heinrich, *C. A.* **25**, 1935.—The increased soly. of soil potash as a result of the application of superphosphate is due principally to the presence of free H_3PO_4 in the superphosphate. The $Ca(H_2PO_4)_2$ and $CaSO_4$ in superphosphate also increase the soly. of soil potash. K. D. JACOB

Superphosphates enriched with ammonia. S. I. VOLFKOVICH, L. E. BERLIN, I. L. HOFMAN AND A. A. IONAS. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 495–504 (1930).—Tests were made of mixing H_2SO_4 with $NH_4H_2PO_4$, with $(NH_4)_2HPO_4$, with a mixt. of both, and with $(NH_4)_3PO_4$. The factors studied were the quant. relationship of the reagents, order of mixing, duration of process and temp. involved. A definite amt. of H_2SO_4 was placed in a Pb container, and the various NH_3 phosphates were added gradually. A stirrer was started and raw phosphates were added slowly, lumping being avoided. The stirring lasted 1–2 min., after which the mixt. was placed in a thermostat at 95–105°. After 3 hrs. the mixt. was weighed, to follow the loss in wt., and placed in thin layers on paper; it was left that way for 2 days and weighed again. Analy-

ses were then made. Total H_2O-sol. and citrate-sol. P_2O_5, were then detd. Methods of prepg. the various NH_4 phosphates, as well as the amts. of H_2SO_4 used with them, are given. J. S. JOFFE

Organic fertilizers. VII. KIYONAO YOSHIMURA, KOTARO NISHIDA AND ARITOMO YAMADA. *J. Agr. Chem. Soc., Japan* **6**, 999–1002(1930).—Steamed bone powder was kept with water for 55 days. The av. temp. was 32.8°. The aq. ext. of the putrefaction products was analyzed: total N 2.550%, protein N 0.044%, P_2O_5 0.019%. Ninety % of total N was changed into NH_3. One g. histamine (Au salt), 3.31 g. putresine-HCl and 280.74 g. NH_4OH were isolated from 10 kg. of the bone powder. Y. K.

The economical and profitable use of commercial fertilizers under present conditions. O. ENGELS. *Kunstdünger u. Leim* **28**, 126–36(1931).—A general discussion. C. J. SCHOLLENBERGER

The use of sawdust as a fertilizer. MARCEL H. MOTTE. *J. agr. prat.* **95**, 192 (1931).—Sawdust used exclusively in large quantities on the soil has generally given an excellent plant growth without any apparent lack of nitrate and with normal nitrification. Artichokes, leeks, sugar beets, maize and strawberries all have produced good crops without any other fertilizer. J. R. ADAMS

The Gerard manure pit. F. MAGNIEN. *J. agr. prat.* **95**, 71–4(1931).—The conditions governing the transformation of barnyard manure into a fertilizer contg. available nutritives are listed. The Gerard manure pit is intended to satisfy these conditions and is described in considerable detail. J. R. ADAMS

Potash fertilizer for sugar beets. J.-PH. WAGNER. *Compt. rend. acad. agr. France* **17**, 77–9(1931).—Sugar beet cultivation calls for a soil with a p_H of 7–7.5, which can be obtained by liming. Max. yields have been obtained when approx. 1,000 kg./acre of sylvinite-kainite has been added to the soil. The yields have amounted to 761 kg of sugar per acre. The large amts. of K_2O aid the plant in obtaining an early and vigorous growth and greater resistance to disease. They also sensibly increase the saccharin content. J. R. ADAMS

The nitrification of ammonium sulfate as influenced by soil reaction and degree of base saturation. JAMES A. NAFTEL. *J. Am. Soc. Agron.* **23**, 175–85(1931).—There appears to be a relationship between the percentage base and Ca satn. and the nitrification of $(NH_4)_2SO_4$. After 10 days' incubation nitrification occurred at p_H 4.1 only in the soil with a high percentage base and Ca satn. Lower base satn. prevented nitrification. All the soils had a higher percentage nitrification of $(NH_4)_2SO_4$ at the highest p_H values studied. In most cases plant growth was better at p_H 6.5 than at the very acid reactions. Nitrification varied considerably in different soils and showed a fairly good correlation with plant growth data. J. R. ADAMS

Experiments with calcium nitrate-I.-G. F. X. KREŠL. *Listy Cukrovar* **49**, 261–2(1931).—The $Ca(NO_3)_2$ was prepd. by the I. G. firm and contained N 15.5% and CaO 28%, which corresponds to 50% $CaCO_3$; the N is rapidly utilized by plants. Expts. were carried out in 18 sections of an estate, with varied results. Because of the sol. form of N, less H_2O is required for soln. than for any other nitrate fertilizer; the $Ca(NO_3)_2$ maintains a porosity during periods of drought, and on account of its fine dispersion the Ca is equally distributed and swells and aerates the soil. Plots fertilized with 400 kg. superphosphate and 200 kg. of a 40% K salt per ha. showed an increased yield of sugar beets over unfertilized plots; adjacent plots fertilized with 100 kg. $Ca(NO_3)_2$ per ha. showed about the same increase as those with the superphosphate mixt. F. M.

The action of chromium on the growth of plants. EL. HASEHLOFF, F. HAUN AND W. ELBERT. *Landw. Vers. Sta.* **110**, 283–6(1930).—The addn. of Cr to the soil has a detrimental action on the plant growth as shown by the effect on the yield of summer barley and mustard. The amts. used were not greater than 0.003%. This action depends on the compd. of Cr used and is greater with chromic acid than with chromic hydroxide. The injurious action is greater in sandy than in loam soils. J. R. H.

The action of arsenic on plant growth. E. HASELHOFF, F. HAUN AND W. ELBERT. *Landw. Vers. Sta.* **110**, 287–9(1930).—Addns. of As up to 0.003% have no effect on the yield of summer barley. This result is not in disagreement with the work of König because different compds. and amts. of As were used. JOHN R. HILL

The nutrition requirements of vegetable plants. I. Cabbage, beet, carrot and onion. FELIKS KOTOWSKI. *Roczniki Nauk Rolniczych i Lesnych* **24**, 372–449 (450–2 English) (1930).—Fertilizer expts. carried out on a rather poor sandy loam in 1928 near Warsaw are described. Beets, carrots and onions were sown in exptl. plots in rows 40 cm. apart. The food supply consisted of mineral fertilizers and stable manure in the ratio of 600 kg. per 100 sq. m. after the tomato crop. Cabbages and carrots received 90 kg. N, 40 kg. P_2O_5 and 120 kg. K_2O; beets 63 kg. N, 28 kg. P_2O_5 and 84 kg. K_2O; onions 28

kg. P_2O_5, 84 kg. K_2O and 63 kg. N per hectare. N was applied as NH_4NO_3, P as superphosphate and K in the form of 26% potash salts. Sampling for chem. analysis was done at various intervals of plant development, the last sample being taken at harvest time. The results are presented in tables and the following conclusions are drawn: For (*a*) Brunswick short stem cabbage, (*b*) dark red flat Egyptian beet, (*c*) Chanteney carrot and (*d*) Zittau onion the max. intake of N, P, K and Ca falls in *a* in the second, *b* in the fourth, *c* in the third and *d* in the fourth months after transplanting of (*a*) and germination of (*b*, *c*, *d*). A crop of (*a*) 500,000 kg. heads and 350,000 kg. refuse parts, (*b*) 500,000 kg. roots and 200,000 kg. leaves, (*c*) 250,000 kg. roots and 80,000 kg. leaves, (*d*) 294,000 kg. bulbs and 72,000 kg. leaves per hectare removes from the soil 150, 122, 80, 80 kg. N; 50, 34, 30, 26 kg. P_2O_5; 225, 200, 120, 116 kg. K_2O; and 180, 76, 100, 58 kg. CaO, resp. The N, P_2O_5 and K_2O ratios are: 3:1:4; 3.5:1:5.5; 2.5:1:4 and 3:1:4.5, resp. As compared with cereals, cabbages, beets, carrots and onions are remarkable for their high N, P, K and especially Ca contents. There is also a considerable difference in the N, P_2O_5 and K_2O ratio, which is on an av. 2:1:2 in cereals and 3:1:4 in the plants reported here. These differences, therefore, should be considered in any fertilizer program. J. KUČERA

The role of humic materials in fertility. A. DEMOLON. *J. agr. prat.* **95**, 109–11 (1931).—The maintenance of humic reserves in the soil is almost always indispensable in maintaining a high fertility and in particular for obtaining the max. use from mineral fertilizers. They are excellent soil conditioners and aid the soil in retaining H_2O. Colloidal humic material increases the nutritive absorptive capacity of soils. The value of farm manure and the manuf. of artificial manure are discussed. J. R. ADAMS

Brief study of (reasons for) beneficial action of brown coal upon the development of cultivated plants. II. ALEXANDER KISSEL. *Brennstoff-Chem.* **12**, 101–7(1931); cf. *C. A.* **25**, 371.—Investigations during 1924–26 with grain growing in arable soil fertilized with coal dust show a growth increase by kernel weight of 24–55%, depending upon the amt. of coal dust used. This is believed due to improved germination and branching rather than to any change in soil compn. Potatoes also showed tuber-weight increases but with sugar beets, the sugar content fell off with root-weight increases. Structural aggregates in the soil are formed by the freshly pptd. water-insol. humic acid salts which lose this cementation property on drying. The impregnation of soil with coal dust or humic compds. thus increases the resistance to water influx into individual soil particles and increases water seepage and aeration in upper soil layers and, in general, restores its fallowness. Small quantities of coal dust increase the soil resistance to machinery, but large amts. decrease it. It is contended that difficulties encountered in the use of artificial agricultural fertilizers are to be traced to factors other than the amt. of mineral matter made available. The structural compn. of the soil, its phys. characteristics and the total content of org. humic combinations are also involved. F. W. JUNG

Decomposition of rotenone in solution. HOWARD A. JONES. *Ind. Eng. Chem.* 23, 387–8(1931).—The decompn. of rotenone is accelerated by access of air but is not affected by differences in amt. of light or by the presence of water. Pyridine solns. of rotenone decompose most rapidly and in a few days crystals of dehydrorotenone and rotenonone are formed by oxidation. Rotenone is completely sol. in benzene, and in a benzene soln. there is no appreciable decompn. Acetone may be used for a water-sol. solvent. J. R. ADAMS

The relation of chemical composition of cultivated and wild green-manure plants to decomposition of the nitrogenous constituents. HIDEO MISU, IWAO OMAI AND TADAO HIBINO. *Ann. Agr. Expt. Sta. Government-General of Chosen* **5**, 1–126(1930).—Twenty-two varieties of cultivated and wild green-manure plants were decompd. by fermentation for 48 days under conditions simulating those in soil with upland and lowland systems of culture. The relations of ammonification, nitrification and the yield of titrable acids to the chem. compns. of green manures are as follows: Ammonification differs greatly with the different raw materials used under both upland and lowland conditions. In upland conditions, it decreases later. Nitrification is negligible under lowland conditions, but it differs greatly under upland conditions with the different raw materials used, and it decreases later. Attainment of max. ammonification is favored by the increase of total N, ash, CaO, or CaO + MgO and disturbed by the increase of crude fiber, N-free ext., crude-fiber protein, and N-free ext./protein. Attainment of max. nitrification is favored by the increase of total N, K_2O and CaO + MgO and disturbed by the increase of crude fiber, N-free ext., and N-free ext./protein. Attainment of max. titrable acidity is favored by the increase of total N and of CaO + MgO and disturbed by the increase of lignin, N-free ext., and N-free ext./protein. The max. ammonification and the

development of max. acidity were greater in lowland conditions than in upland conditions. K. KITSUTA

Availability of nitrogen of green manure for rice and the supplementary value of various fertilizers. HIDEO MISU AND H. SHIMOHIRA. *Ann. Agr. Expt. Sta. Government-General of Chosen* 4, 65–94(1929).—The availability of N was lower in dried than in fresh green manure. The value of N of dried green manure was greatly increased by replacing $^1/_2$ of the N with $(NH_4)_2SO_4$. Although the N of fresh material appeared less available, the yield obtained was better than that with fermented green manure. Superphosphate, K_2O and CaO had great value as supplements to green manure, increasing availability of the N and yields. Yields with fresh green manure were 83.4 and 89.3% of those with soy-bean cake and $(NH_4)_2SO_4$, resp. K. KITSUTA

The availability of nitrogen of air-dried green manures for rice. HIDEO MISU. *Ann. Agr. Expt. Sta. Government-General of Chosen* 4, 167–72(1929).—Green manures showed lower availability of N and lower yield than did soy-bean cake and $(NH_4)_2SO_4$. K. KITSUTA

Nitrogen in the intensive exploitation of pastures. CAMILLE MATIGNON. *Chimie & industrie* 25, 271–5(1931).—A discussion is given of the advantages, from the double standpoint of yield andqua lity, of the use of N fertilizers on pasture lands. A. P.-C.

Comparative value of nitrogenous fertilizers on the growth of fall and spring barley. IWAO OMAI. *Ann. Agr. Expt. Sta. Government-General of Chosen* 3, 347–54(1930).—Among 15 tested materials Chilean $NaNO_3$ and $(NH_4)_2SO_4$ gave the highest percentage of recovery of N by the plants (60–66%) and the best yield. $CaCN_2$, dried fish meal, dried blood, soy-bean cake, bone meal and human excrement showed 45–55% recovery of applied N by the plants with 68–87% yield compared with the yield by $(NH_4)_2SO_4$ as 100%. Heavy application of mulch made of weeds was rather injurious on the first crop as a result of its fermentation, and the benefit to the second crop was small in comparison with the loss of N by fermentation. The efficiencies of the N in stable manures from swine and cattle were very small. The value for the second crop of any residual N after the first crop was rather small. K. KITSUTA

The effect of various fertilizer treatments on the crop-yield factors and the structure of leaves of barley and wheat. K. BOEKHOLT. *Z. Pflanzenernähr., Düngung u Bodenk.* 9B, 289–300(1930).—Stooling, weight per 1000 grains, grains per single head, weight of grains per head and total yield are affected by various single fertilizers and combinations. K has little effect on stooling, P more and N most. The 1000 grain weight and weight per single head are least with N. A mixt. of N, P and K usually gave the highest values for all the factors mentioned and always the highest yield. The leaf surface varies with the fertilizer treatment, *e. g.*, if no treatment is 100, then a mixt of K and P is 97.8, a mixt. of K and N 128.9, a mixt. of P and N 144 4, a mixt. of K, P and N 134.7, and 2 pts. K, 1 pt. P and 1 pt. N 136 7. The microanatomic structure also varies with different fertilizer treatments. H. B. SIEMS

Effect of ammonium sulfate on field germination of rape and turnips. J. W. WOODCOCK. *New Zealand J. Agr.* 42, 89–90(1931).—Germination of rape and turnip seed fertilized with $(NH_4)_2SO_4$, either alone or mixed with other fertilizer materials, at the rate of 100 lb./acre was only 10 to 44% of the germination obtained when the seeds were fertilized only with a mixt. of 100 lb. of superphosphate plus 10 0 lb. of ground limestone Fertilization with superphosphate alone gave germination counts 66 to 100% of those obtained with the mixt. of superphosphate and ground limestone. In all cases the fertilizers were applied with the seed in 14-in. rows. K. D. JACOB

Fertilizer experiments on citrus seedlings. I. TAKAHASHI. *J. Okitsu Hort. Soc.* (Japan) 25, 38–50(1930).—Pot expts. with seedlings indicated that N is the most necessary element for growth. The requirements of P_2O_5 and K_2O were $^1/_2$ and $^2/_3$, resp., of the N requirement. Requirement of P_2O_5 for growth of the citrus tree was not very great, but deficiency of this element retarded growth markedly. The requirement of K_2O was greater than that of P_2O_5; however, the growth continued uninterruptedly without K_2O for a certain time by compensation with the supplement of the other elements. K. KITSUTA

Fertilizer experiments with Satsuma orange. K. TASAKI, Y. INOUE AND N. MATSUOKA. Imp. Hort. Expt. Sta. (Japan), *Research Bull.* 13, 60 pp.(1930).—Plots were arranged into those with no fertilizer, N, P or K and complete fertilizer treatment. No fruit was obtained from the trees in the plot without N. When P was omitted, the yield was much decreased, and the acidity of the fruit was high. Lack of K caused decrease in yield, poor color of skin and small sized fruits; the spoilage of fruits during storage was 5.5 times higher than that of the fruits from the completely fertilized plot. K. KITSUTA

Is fertilization to prevent frost injury practical? WALTER OBST. *Kunstdünger u. Leim* 28, 26–7(1931).—The resistance of plants in general toward injury from cold is increased by complete fertilization, excess N being avoided. C. J. S.

The importance of artificial fertilizers in modern pond culture. K. HEITZ. *Kunstdünger u. Leim* 28, 27–8(1931).—Growth of plankton serving as food for fish is greatly increased by proper fertilization with K_2O and P_2O_5. The application of CaO to a drained pond during winter is advised as a sanitary measure. C. J. SCHOLLENBERGER

Carbon dioxide in relation to glasshouse crops. V. An analysis of the response of the tomato crop to an atmosphere enriched with carbon dioxide. H. L. WHITE. *Ann. Appl. Biol.* 17, 755–66(1930).—The enrichment of the atm. has the following effects upon the tomato plant: It shortens the period between opening of the flower and picking of the fruit. A high percentage of blossoms develop into fruit. Less fruit is retarded in ripening. There is better development of the truss. There is earlier development and ripening of trusses. There is better swelling of fruit at end of season. Conclusion: Increased CO_2 concn. is most beneficial to the plant at periods of low fruit production. C. H. RICHARDSON

A study by foliar diagnosis of the influence of temperature on plant nutrition. H. LAGATU AND L. MAUME. *Compt. rend.* 190, 1516–8(1931); cf. *C. A.* 24, 4575; 25, 2234.—Potatoes were grown on plots receiving various fertilizer treatments, and the leaves were analyzed for P at intervals. During May the temp. averaged about 14°, and the P content remained rather const. During June, when the temp. averaged 21°, the P content decreased markedly on the plots which received N, but did not on those without N. The explanation offered is that with added N tuber development is more abundant, and this tends to deplete the P in the leaves. J. J. WILLAMAN

Some studies on the use and action of mercuric chloride as a fungicide. J. L. HOWATT. *Twenty-first Ann. Rept. Quebec Soc. Protect. Plants* 1928–9, 40–2(1929); *Rev. Applied Mycol.* 10, 196–7.—The control of fungicides in certain seed-borne diseases by use of $HgCl_2$ is due to retardation of the germination of the spores sufficient for them to be outgrown by the host and so removed from the meristematic tissue. Stimulation of the seed after treatment is attributed to indirect partial sterilization effect on the soil. Temp., concn., time of action, age of spore and host plants, assocn. and type of seed are considered to affect the toxicity. ODRN E. SHEPPARD

Titrimetric determination of arsenic in plant-protecting agents. J. PÁSKUJ. *Magyar Chem. Folyóirat* 36, 76–83, 95–101(1930).—The agents are destroyed with HNO_3 and H_2SO_4, then dild. to a concn. of about 50% H_2SO_4. Now 50 cc. concd. HCl, 5 g. crystd. $FeSO_4$, and 2 g. KBr are added, 25 cc. is distd. and As titrated in the distillate according to Györy with 0.1 *N* $KBrO_3$ soln. Detns. may thus be made within 1–5 hrs. Also a micromethod was worked out, the results of which quite agree with those of the macromethod. Hydrazine sulfate should replace the $FeSO_4$ in the micro-detn. S. S. DE FINÁLY

The biochemical influence of arsenic. J. PÁSKUJ. *Magyar Chem. Folyóirat* 36, 111–8(1930).—Spores of *Tilletia tritici*, Bjerk Winter, adsorb some As of H_3AsO_4 and arsphenamine but no As of other arsenicals, either inorg. (arsenites, arsenates) or org. (arsacetin, atoxyl, solarson, cacodylic acid, etc.). Adsorbed As does not kill spores but hinders their multiplication. Agents of which no As is adsorbed have no influence at all on spores. Spores treated with arsenites and dried without washing off the agent were killed. Arsenates did not show such results. S. S. DE FINÁLY

Effect of arsenic on the composition of citrus fruits. I. TAKAHASHI. *J. Okitsu Hort. Soc.* (Japan) 25, 153–63(1930).—Spraying citrus trees with arsenates caused a decrease in acidity and an increase in sugar content of fruit juice. The reduction of acidity depends greatly upon the time of spraying, amts. of other spraying materials mixed with arsenate and the method of application. Excessive use of arsenate should be avoided, as it affects the yield and taste of fruit. A decrease in acidity and an increase in sugar content of fruit caused poor keeping quality; therefore, in warmer regions caution must be exercised in spraying with arsenicals. Beside controlling harmful insects, spraying arsenates may be of benefit by hastening maturity or reducing excessive acidity of fruit. K. KITSUTA

Effects of some sulfur sprays on fruit-bud development. C. E. PETCH AND J. L. HOWATT. *Twenty-first Ann. Rept. Quebec Soc. Protect. Plants* 1928–9, 39(1929); *Rev. Applied Mycol.* 10, 197.—Comparative tests of koloform (prepd. by fusing bentonite with S, with Ca caseinate added to assist the mixing in water) and lime-sulfur on the development of apple trees shows that koloform-treated buds were 0.4903 in. long when those sprayed with lime-sulfur were 0.3979 in. long. This difference is attributed to absence of injury in koloform-treated foliage, whereas burning and dwarfing of foliage

was evident on the trees treated with lime-sulfur. Koloform was applied at the rate of 8 lbs., and lime-sulfur at the rate of 1 gal. to 40 gals. water. ODEN E. SHEPPARD

The mineral nutrition of plants in relation to their predisposition or resistance to attack by pathogenic agents. L. PETRI. *Boll. R. Staz. Pat. Veg. N. S.* **10**, 121–52 (1930); *Rev. Applied Mycol.* **10**, 200.—The action of different fertilizers (including nitrogenous and phosphatic fertilizers, lime, sulfur, gypsum, potash, iron and aluminum sulfates, and manganese salts) on the anatomical and physiol. properties of plants with reference to their resistance to injurious inorg. agencies as well as to various fungus and animal parasites was studied. In general, nitrogenous dressings aggravate susceptibility, whereas phosphatic and potash dressings reduce it. The action of the fertilizer is indirectly on the mechanism of the host resistance and is influenced by local factors; comparative tests must be carried out under identical conditions. ODEN E. SHEPPARD

Spraying and dusting experiments with potatoes on Long Island. H. C. HUCKETT. N. Y. State Agr. Expt. Sta., *Bull.* No. 592, 1–38(1931).—Expts. in spraying and dusting Irish Cobbler (I) and Green Mountain (II) potatoes have been conducted during 5 successive seasons, 1926–1930. With the exception of applications contg. nicotine, Bordeaux mixt. (4–6–50) was used in sprays and $CuSO_4.H_2O$ and $Ca(OH)_2$ (20–80) for dusts. For biting insects $CaAsO_4$ was added to Bordeaux mixt. at the rate of approx. 5 lbs. or to dust mixts. at 10–12 lbs. per acre. Arsenical treatments were usually made 3–4 times each season to combat Colorado beetle and flea beetles. For sucking insects nicotine sulfate (40% soln.) was added to Bordeaux mixt. or a mixt. of dolomite and $Ca(OH)_2$ (10–50) at the rate of about 1 pint or 3 pints per acre, resp. There were no significant differences in the results from dusting and spraying in the case of I. Also nicotine treatments in spray or dust form did not give rise to addnl. increases in yield over other spraying and dusting operations. With II Cu treatments in spray form gave on an average slightly superior results to Cu treatments in dust form. Nicotine treatments in dust form were more reliable, and in years when aphids were a limiting factor gave superior results to nicotine in spray form. J. KUČERA

The effect of gypsum upon the growth and common scab of the potato. J. G. COULSON. *Twenty-first Ann. Rept. Quebec Soc. Protect. Plants* **1928–9**, 64–80(1929); *Rev. Applied Mycol.* **10**, 202.—Increasing applications of gypsum above 500 lbs. per acre in field tests progressively reduced the number of tubers formed and gave an increased amount of scab infection. A lab. test showed that addn. of gypsum did not effect the p_H of the soil. Addn. of gypsum to potato dextrose agar from 0.5 to 50% caused no difference in the rate of growth of *O. scabies*. ODEN E. SHEPPARD

Seed treatment for controlling covered smut of barley. R. W. LEUKEL. *U. S. Dept. of Agr. Tech. Bull.* **207**, 1–22(1930); *Rev. Applied Mycol.* **10**, 173–4.—Satisfactory control of covered smut (*Ustilago hordei*) of barley was obtained by steeping the seed grain for 1 hr. in either 1 in 320 formaldehyde, 0.5% semesan, 0.5% corona 620, 0.5% uspulun, 0.25% germisan, 0.25% tillantin or 0.5% Bayer compd. Expts. with more than 45 dusts indicated that their effectiveness is independent of soil reaction, but a soil moisture content of less than 25% satn. decreases the efficacy of most dusts. Hochst, abavit B, and ceresan are the most effective dusts and give satisfactory control. Use of dusts avoids the seed injury common with steeping treatments, and thus better stands and yields are obtained. ODEN E. SHEPPARD

Dry pickling for control of smut in oats. W. B. MILLER AND J. A. MORROW. *J. Dept. Agr. Victoria* **29**, 86–9(1931).—Good control was obtained by dusting the seed with Cu carbonate at the rate of 2 oz. per bushel. Treatment of the seed with formalin solns. gave better control of the smut but adversely affected germination of the seed. K. D. JACOB

Action of low potencies. W. MAAG. *Süddeutsche Apoth.-Ztg.* **71**, 143–5(1931).—The results obtained in a series of expts. on the germination of wheat in the presence of varying low potencies of HCl, H_2SO_4 and $CuSO_4$ are illustrated, as also those obtained with paper strips vertically suspended and just dipping into varying potencies of KOH and H_2SO_4. W. O. E.

Control of the webbing spider (Lampona obscoena) of citrus trees. S. A. COCK. *J. Dept. Agr. Victoria* **29**, 83–5(1931).—Good control is obtained by spraying the webs with an emulsion of 2 pints of kerosene and 4 ounces of soap in 3 gallons of water to which is added 1.5 lb. of pyrethrum. The kerosene serves to penetrate the web, while the pyrethrum acts as the killing agent. K. D. JACOB

The destruction of weeds by chemical procedures. M. BARBUT. *J. agr. prat.* **95**, 9–11(1931).—Comparisons are made of the efficacy of the weed eradicators used for those weeds which are harmful to cereals. A 6–8% soln. of H_2SO_4 gives excellent results, destroying charlock, chenopodium and polygonum. The objection is that it is

very active in deliming the soil. Dehydrated iron sulfate and a nitrocopper compd. are very effective against charlock, but both these materials are somewhat more expensive. A special powd. sylvinite is perfectly satisfactory against some of the weeds such as charlock, but great care must be used, as large quantities of this material are injurious to the crop. J. R. ADAMS

Cucumber disease investigations on Long Island. E. E. CLAYTON. N. Y. State Agr. Expt. Sta., *Bull.* No. 590, 3–20(1931).—The cucumber diseases, mosaic, wilt and mildew or blight, can be best checked by treating the seeds with org. Hg compds. when the seed is sown early, by using wet and dry sprays with dust mixts. such as $Ca_3(AsO_4)_2$ + $CaSO_4.2H_2O$ (1:15), copper-lime, kayso-$Ca_3(AsO_4)_2$ (3–3–50) and by breeding disease-resistant varieties. Spraying does not control mosaic. J. K.

Study of the warble and its eradication. A. GANSSER. *Schweiz. Leder-ind. Ztg.* **1930**, No. 3/4; *J. Intern. Soc. Leather Trades Chem.* **14**, 324; cf. *C. A.* **20**, 2223.—The hypocotine (nicotine salve) treatment previously described has worked well in practice. The treatment seems to have a lasting prophylactic effect. H. B. M.

Recovering of NH_3 in beet-sugar manufacture [for use as fertilizer] (VOSTOKOV, KOTLYARENKO) **28.** Detection of F in soils (RECKENDORFER) **7.** Organic solvents for aiding the removal of spray residue from waxy or oil-covered fruit (ROBINSON) **12.** Estimating the solubility of acid Pb arsenate within the alimentary tract of the silkworm (CAMPBELL, LUKENS) **11I.** Quinquennial review of the mineral production of India for the years 1924 to 1928. Saltpeter (PASCOE) **18.** $(NH_4)_2SO_4$ (Hung. pat 101,900) **18.**

KEEN, BERNARD A.: **The Physical Properties of the Soil.** New York: Longmans, Green and Co. 380 pp. $8.

VERMOREL, V.: **Agenda agricole et viticole, 1931.** Paris: Dunod. 384 pp. F. 6.50.

Reagent for treating alkali soils. CHINOIN, LTD. Hung. 101,149, Jan. 4, 1930. S bacteria and NH_4 salts are added to a mixt. of powd. gypsum and S; *e. g.*, a mixt of 45% $CaSO_4$ is made of 4.5% S and 50.5% powd. peat inoculated with S bacteria

Fertilizers. CHEMIEVERFAHREN G. M. B. H. Fr. 37,452, Sept. 21, 1929. Addn to 682,081 (*C. A.* **24**, 4351). Crude phosphate is attacked with HNO_3, and the Ca is pptd. as $CaSO_4$ by a mixt. of K_2SO_4 and $MgSO_4$ or a corresponding natural compd The amt. of Mg is equiv. to that of P_2O_5 in conformity with the formula $MgHPO_4$. The $CaSO_4$ is pptd., K_2CO_3 is added to the soln. to ppt. $MgHPO_4$ and the rest of the P_2O_5 is pptd. as $Mg_3(PO_4)_2$ by adding more K_2CO_3. KNO_3 is obtained by evapn.

Fertilizers. ODDA SMELTEVERK AKTIESELSKAP and ERLING JOHNSON. Fr. 37,494, Oct. 7, 1929. Addn. to 682,423 (*C. A.* **24**, 4351). The soln. contg. phosphoric acid obtained by treating natural phosphates with HNO_3 is neutralized or caused to react with substances forming a fertilizer, such as NH_3, compds. of NH_3 and CO_2, urea, cyanamide or its salts or natural phosphates, so that on removing the water a dry stable fertilizer is obtained. Other salts of K, NH_4, etc., may be added in the solid state

Fertilizers. ÉDOUARD URBAIN. Fr. 695,221, Aug. 29, 1929. A fertilizer contg. P_2O_5 30–34, K_2O 8–11 and N 10–11% is made by using natural phosphate and aluminosilicate rocks in suitable proportions. Lime is introduced in such amt. that a utilizable slag is obtained.

Fertilizers. I. G. FARBENIND. A.-G. Fr. 37,217, July 16, 1929. Addn. to 673,093 (*C. A.* **24**, 2538). Compd. fertilizers are prepd. contg. NH_4NO_3 but not $CaCO_3$.

Fertilizers. HERBERT J. KRASE, HARRY C. HETHERINGTON and LOUIS A. PINCK (to Arthur B. Lamb, trustee). U. S. 1,797,095, March 17. See Fr. 678,693 (*C. A.* **24**, 3599).

Fertilizers. ODDA SMELTEVERK AKTIESELSKABET and E. JOHNSON. Brit. 339,340, Oct. 27, 1928. See Fr. 662,423 (*C. A.* **24**, 4351).

Calcium phosphates and fertilizers. ODDA SMELTEVERK AKTIESELSKABET and E. JOHNSON. Brit. 339,500, Dec. 14, 1928. The mother liquor obtained by treating rock phosphate with HNO_3 and sepg. a substantial proportion of $Ca(NO_3)_2$ by cooling as described in Brit. 339,340 (preceding abs.) is treated with gaseous or aq. NH_3, NH_4 carbonate or alkali metal carbonate; pptd. di-Ca phosphate is sepd., and the filtrate is used for the production of products contg. N and phosphoric acid, or the di-Ca phosphate may be treated together with the soln. to obtain solid products. By suitably restricting the quantity of $Ca(NO_3)_2$ sepd., relatively pure NH_4NO_3 can be obtained by evapg. the filtrate. Production of tri-Ca phosphate and various fertilizer mixts also is described.

Fertilizer comprising urea and calcium nitrate. I. G. FARBENIND. A.-G. Brit. 338,644, Sept. 16, 1929. A fertilizer contg. the double compd. of urea and $Ca(NO_3)_2$ is prepd. by melting together the anhyd. components preferably in the mol. proportions of 4 and 1, resp., and subdividing by spraying or other suitable treatment. Oil may be added to increase the stability of the product in storage. Cf. *C. A.* **25**, 554.

Mixed ammonium compounds suitable for use as fertilizer. R. TERN. Brit. 338,869, Aug. 22, 1929. Gases produced by roasting crude S or spent oxide from gas and coke-mfg. plants are mixed with ammoniacal gases produced by heating the gas-water from the scrubbers, and the material is ionized by a high tension current of 70,000–80,000 v., a mixt. being produced which comprises NH_4 sulfate, sulfite and imidosulfonate and other compds. of S and NH_4, which may be elec. pptd.

Stimulant for tap roots and tubers. I. G. FARBENIND. A.-G. (Georg Wesenberg and Eduard Bischkopff, inventors). Ger. 515,884, Mar. 28, 1926. Salts of polythionic acids act as a stimulant and increase potato, turnip, etc., yields. Examples state that mixts. of $Na_2S_2O_3$ or BaS_2O_3 or $CuS_2O_3.Na_2S_2O_3$, with kieselguhr, cause 20–50% increases in potato crops.

Fungicides. I. G. FARBENIND. A.-G. (Adolf Steindorff, Kaspar Pfaff and Georg Dahmer, inventors). Ger. 518,097, Mar. 30, 1928. Products comprising finely divided $Cu(OH)_2$ pptd. in the presence of fatty acids of high mol. wt. (or their salts) are used. Thus, wool-fat acids may be dissolved in NaOH, the soln. treated with solid $CuSO_4$ and the pasty product mixed with talc, dried and ground.

Organo-mercury compounds. T. W. F. CLARK. Brit. 338,963, Aug. 29, 1929. Phenolphthalein, fluorescein or their homologs or halogen derivs. are treated with Hg oxycyanide (or a mixt. of Hg oxide and an alkali cyanide), or reaction is effected with an alkali cyanide on Hg compds. of phenolphthalein, fluorescein or their homologs or halogen derivs. contg. the group HgX in which X represents OH, NO_3, SO_4H, halogen, etc. The *products are bactericides and fungicides.* Several examples are given.

Insecticides. ÉTABLISSEMENTS ET LABORATOIRES GEORGES TRUFFAUT. Fr. 695,164, Aug. 16, 1929. Insecticide solns. are prepd. by adding as adhesive one or more substances which lower the surface tension of water such as sulfite cellulose lyes, substituted amides of fatty acids or salts of sulfonic acids.

Insecticides. UNION CHIMIQUE BELGE. Ger. 515,633, Aug. 21, 1929. Prepns. contg. the insecticidal constituents of *Pyrethrum cinereafolium* are obtained by extg. the plant with hydrocarbon solvents, evapg. off the solvent and dissolving the residue in pyridine or ethyl lactate. Examples describe the extn. of the pulverized flowers with such solvents as pyridine, petroleum ether and alc.

Insecticide and fumigant. GUY H. BUCHANAN (to American Cyanamid Co.). U. S. 1,795,593, March 10. A compn. is described which comprises the reaction product formed by fusing together of Ca cyanamid, C and NaF.

Pest-destroying composition. PERMUTIT A.-G. (Otto Liebknecht, inventor). Ger. 515,348, June 15, 1926. Addn. to 472,738 (*C. A.* **23**, 3049). Seed goods, etc., are protected against animal and vegetable pests by a powder contg. insol. or nearly insol. Cr compds. instead of the gaseous Cr compds. of 472,738. The prepn. may contain $Cr(OH)_3$, Cr_2O_3, CrF_3, $CrPO_4$, chromates and bichromates, mixed with talcum, etc.

Composition for protecting plants. CHINOIN GYÓGYSZER ÉS VEGYÉSZETI TERMÉKEK GYÁRA R. T. (KERESZTY ÉS WOLF). Austrian 120,877, Aug. 15, 1930. Plant-protecting compns. comprising an aq. dispersion of S and a hydrocarbon are prepd. by stirring a concd. aq. soln. of $(NH_4)_2S$ and a hydrocarbon contg. an emulsifying agent into a large amt. of water. The hydrocarbon may be petroleum or tar oil, preferably free from phenol, and the emulsifying agent may be Turkey-red oil or an NH_4 soap. Examples are given.

Preventing infection of plants. ÉTABLISSEMENTS ET LABORATOIRES GEORGES TRUFFAUT. Fr. 695,165, Aug. 16, 1929. Cryptogamic infections of plants are combatted by the use of org. dyes, such as dimethyldiaminonaphthophenasoxonium hydrochloride, mixed with products which lower the surface tension of water.

Disinfecting seeds. IGNAZ KREIDL. Austrian 121,349, Sept. 15, 1929. Fungicides are applied in paste or pulp form, *e. g.*, by mechanically mixing the seeds with the paste or pulp. Fungicides sol. or insol. in water may be used, and solid diluents, glycerol, etc., may be included in the mixts. Examples are given.

Dry-cauterizing seed goods. I. G. FARBENIND. A.-G. (Wilhelm Bonrath, Wilhelm Schepss and Carl Taube, inventors). Ger. 515,957, June 7, 1928. The goods are treated with alkyl Hg compds. of the general formula RHgX, where R = an aliphatic hydrocarbon residue and X = OH or an acid residue. Examples mention talcum and C mixed with EtHgCl, PrHgBr, BuHgAcO or EtHgAcO.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Formation of kojic acid from sugars by Aspergillus oryzae. FREDERICK CHALLENGER, LOUIS KLEIN AND T. KENNEDY WALKER. *J. Chem. Soc.* **1931**, 16–23.—A strain of *Aspergillus oryzae* was used in these expts. in a medium contg. inorg. salts and designated "medium K." (Cf. *C. A.* **23**, 4966.) Two expts. were made with dihydroxyacetone, one contg. 11 cc. of medium K and 0.5 g. of dihydroxyacetone, the other contg. 5% dihydroxyacetone. The temp. of incubation was 31–2°. Kojic acid was identified in both cases by its m. p. and further characterized in the form of the diacetyl deriv. Kojic acid was also obtained by the fermentation of glycerol by a strain of *Aspergillus oryzae*. Fermentation expts. with 5% ethylene glycol, 2% Ca gluconate, 2% KH saccharate, 2% K citrate and 1% glyceric acid were neg. The action of *Aspergillus niger* on glycerol was studied. Trioses were produced when *Aspergillus niger* acted upon a 5% glycerol soln. with the salts of medium "M." After 9 days the liquid was filtered, made faintly alk. with ammonia, concd., pptd. with Pb acetate and decompd. with H_2S. Oxalic acid was obtained and identified by titration with 0.02 *N* NaOH and 0.02 *N* $KMnO_4$ and by formation of the di-*p*-bromophenacyl ester. Neither tartronic nor saccharic acid could be detected. S. JOZSA

Selective fermentation. II. Fermentation of sugar mixtures by Sauterne yeast. HARRY SOBOTKA AND MIRIAM REINER. *Biochem. J.* **24**, 1783–6(1930); cf. *C. A.* **25**, 166.—Sauterne yeast ferments fructose preferably to glucose in a mixt. B. H.

Notes on the determination of cane sugar in sweet wines. H. JAHR. *Z. anal Chem.* **83**, 321–38(1931).—The detn. of sugar in wine was carefully studied and it is pointed out that in detg. cane sugar it is necessary to proceed as in the detn. of the original reducing sugar and use Pb acetate together with AcOH. It is recommended, moreover, to simplify the official method of analysis as follows: If the wine contains, *e.* g. of ext. per l., take about $3000/e$ g. for the analysis. Weigh out the sample accurately in a weighing beaker, transfer to a 100 cc. measuring flask and make up to the mark at 15°. Shake and transfer to a somewhat larger dry flask. Add 1.5 g. of freshly ignited bone-char and allow to stand 10 min. with occasional mixing. For the detn of the directly reducing sugar, take 25 cc. of the filtrate in a 150-cc. measuring flask and neutralize with *N* NaOH. Make up to the mark at 15°, treat 50 cc. with Fehling's soln. as in the official method. Take 50 cc. of the filtrate from the bone-char clarification for the detn. of the cane sugar. Make up to 75 ml. in a measuring flask with marks at 75 cc. and 100 cc. and invert according to the official directions. After the inversion, take 50 cc., dil. to exactly 100 cc., neutralize with NaOH and treat with Fehling soln. as in the detn. of the original reducing sugar. W. T. H

The acidity of wine and the new (French) regulations. L. FERRÉ. *Ann. fals* **24**, 75–80(1931).—A plea for the adoption of more precise definitions of total, free and volatile acidity, and for the adoption as official of methods capable of yielding results conforming with the definition thus adopted. A. PAPINEAU-COUTURE

Detection of fruit wine in grape wine by Werder's sorbitol method. A. SCHREMPF. *Chem.-Ztg.* **55**, 52(1931); cf. *Chem.-Ztg.* **54**, 765, 997(1930).—S. states that the cause of contradictory results is due to samples contg. very small quantities of fruit wines. The method of detn. is discussed, the difficulties are emphasized and greater accuracy is suggested. Conclusion: The accuracy and reliability of the method do not depend primarily upon the size of the sample to be analyzed. S. JOZSA

Brandy wines and wine-brandy products. H. ZELLNER. *Chem.-Ztg.* **54**, 925–8 (1930).—The summary and conclusions of 246 analyses are given. The fusel oil and ester content of brandy wines, distillates and wine brandies are discussed. The figures obtained for yield do not give reliable results in every case, and it is necessary to taste the product for complete estn. The importance of the sense of taste is emphasized and its correlation to various analytical results set forth. S. JOZSA

Infectious turbidity in beer. DE GRONCKEL. *Bull. assoc. élèves inst. sup. fermentations Gand* **32**, 117–25(1931).—An address dealing with causes and remedies A. PAPINEAU-COUTURE

Brewery yeast in the chemical industry. FABER. *Brasserie & malterie* **21**, 13–5 (1931).—The possibility of production of nucleic acid, amino acids, ergosterol, vitamins and bios from brewery yeast is briefly discussed. A. PAPINEAU-COUTURE

The supposed relation between p_H value and acid taste of wines (CRISCI) 12. Control and regulation of distilling columns (PÉRARD) 13. The methylene-blue staining

of yeast cells and studies on the permeability of the yeast-cell membrane (FINK) **11B.** **Activating metals or alloys** [for vessels for yeast] (Austrian pat. 121,243) **3.** **Lining** [fermentation vats] (Austrian pat. 121,533) **13.** **Apparatus for mixing materials added** [to beer passing to a filter] (Brit. pat. 338,945) **1.**

Rectifying alcohol. SOC. ANON. DES DISTILLERIES DES DEUX-SEVRES. Fr. 695,214, Aug. 27, 1929. In the direct rectification described in Fr. 689,914 (*C. A.* **25**, 1030) the first purification is carried out on a liquid titrating at most a few degrees Gay-Lussac and of which at most 3% is vaporized and treated, any concn. of the alc. being avoided.

Denaturing alcohol. I. G. FARBENIND. A.-G. Fr. 37,197, July 6, 1929. See Ger. 513,410 (*C. A.* **25**, 1329).

Non-alcoholic beverage. JOSEF PARSCHIK. Austrian 121,415, Mar 15, 1930. A mash from incompletely saccharified malt, with or without fruit juices, is fermented with a coccoid bacillus of the lactic acid group cultivated from bread leaven. The mash is fermented until an acidity of about 0.15%, calcd. as lactic acid, has developed. It is then cooled, satd. with CO_2, filtered and bottled. Cf. *C. A.* **24**, 5085.

Dealcoholizing alcoholic liquids such as fermented beverages. HERMAN HEUSER (to U. S. Process Corp.). U. S. 1,796,022, March 10. The liquid is heated to vaporize alc. from it and the vapors are passed through a cooling zone in indirect conductive contact with aq. cooling liquid, to condense the alc.; the uncondensed constituents of the vapors are withdrawn and the alc. condensate and aq. cooling liquid are combined. App. is described.

Alcohol from fermented wines, musts, etc. É. A. BARBET. Brit. 338,569, May 16, 1929. In a process in which wines or the like are first distd and then rectified, with use of heat of the distn. vapors for rectification, the rectification is effected in 2 stages, the second rectification being effected solely by the heat contained in the alc. vapors (suitably *in vacuo*). Various details of app. and procedure are described.

Stopping alcoholic fermentation. L. VÁSONY. Hung. 101,986, July 4, 1930. Yeasts are pptd. to clarify the turbid must. The new yeasts making the clarified must again turbid are pptd. in turn, and this procedure is repeated until bottom fermentation begins. Now must is sucked off the bottom yeasts repeatedly until the must produced remains pure, contg. no nutrient matter for yeasts.

Malting cereals. T. R. DIXON. Brit. 339,047, Oct. 7, 1929. The cereals are treated with a soln. of an org. acid such as lactic acid as soon as the testa is broken by natural growth or after germination, in order to stimulate and accelerate the action of the enzymes of the grain.

Beer. EDUARD JALOWETZ and MAX HAMBURG. Austrian 121,348, Nov. 15, 1928. $CaSO_4$ or $CaCl_2$ is added to brewery water or to the mash or the wort, whereby beer contg. a reduced proportion of deleterious albuminous constituents is obtained. The amt. of salt to be added is detd. by estg. the NH_3 content of the beer, since the deleterious albumins readily split off NH_3. A method of estg. the NH_3 content is described.

Yeast fermentations. ERNST REINISCH. Austrian 121,078, Aug. 15, 1930. The fermentation with yeast of mashes of all kinds is improved by subjecting the water initially supplied to the yeast, and also the yeast-free mash, to regulated treatment with ultra-violet rays, with or without oxidizing salts that do not retard the fermentation. The method may be applied in prepg. a pressed yeast rich in vitamins.

Biologically active yeast preparations. M. MOSKOVITS. Hung. 101,496, Dec. 27, 1928. Life activity of yeast is stopped with 20% alc. The alc. ext. is distributed in liqueurs, bonbons or jelly-contg. pills.

Yeast with high enzyme activity. M. MOSKOVITS and KRAUSZ-MOSKOVITS, LTD. Hung. 100,910, March 22, 1929. Yeast is produced in dild. mash under aeration. Enzyme activity is increased (1) by diminishing aeration, which retards multiplication, and addn of N-contg. food, which improves the plasma, (2) by using a mash that contains much carbohydrate.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Microchemical identification of alkaloids. J. F. H. AMELINK. *Pharm. Weekblad* 68, 921-9(1931); cf. *C. A.* **25**, 2241.—*Harmine* and *harmaline* (dihydroharmine) as HCl salts in concns. as low as 0.1% give cryst. ppts. with $PtCl_4$, $AuCl_3$, $HgCl_2$, $K_4Fe(CN)_6$ $K_3Fe(CN)_6$, Dragendorff's reagent, and KOH. A sp. reaction of harmaline is the blood-

red color obtained on warming it with AcH. The red product is sol. in $CHCl_3$ and 90% EtOH, but insol. in Et_2O. A. W. Dox

Aconitine from Cashmerian Aconitum chasmanthum. K. H. Bauer and Tara Chand Radjhan. *Pharm. Zentralhalle* **72**, 146–52(1931).—An aconitine which differed from all aconitines hitherto reported was isolated from the Cashmerian aconite. The m. p. and cryst. form are identical with those found for indaconitine, but differs markedly in being insol. in Et_2O. W. O. E.

Examination of liquor cresoli saponatus. H. Noerdlinger. *Süddeutsche Apoth.-Ztg.* **71**, 159–61(1931).—The method suggested by Kaiser has been subjected to renewed study with the conclusion that it cannot be depended upon to reveal the true compn. of cresol soap soln. In the absence, therefore, of a better method, recourse should be had to the official pharmacopeial procedure. W. O. E.

New drugs and pharmaceutical specialties during the 4th quarter of 1930. F. Zernik. *Süddeutsche Apoth.-Ztg.* **71**, 165–8(1931).—The more important novelties of this period are enumerated and to some extent described. W. O. E.

Percolation or diacolation. Breddin. *Süddeutsche Apoth.-Ztg.* **71**, 172–3(1931); cf. *C. A.* **24**, 4896.—The apparent phys. and hence economical advantages of the diacolation method (involving multiple cylinders) over percolation (the so-called American method) in the extn. of crude drugs are emphasized and fully discussed. W. O. E.

The reactions of novocaine. L. Ekkert. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 221(1930); cf. *C. A.* **24**, 4897.—A dark red to carmine-red color is formed by adding 2 drops of 10% $NaNO_2$ soln. and 10 drops of an alk. soln. of α-naphthol to dil. HCl contg. a soln. of novocaine chloride or nitrate. The soln. of novocaine is mixed with 10 drops of $CaOCl_2$ soln. and 0.01 g. phenol and NH_4OH added. The mixt. becomes green on warming. A soln. of chloramine may be used instead of the $CaOCl_2$ soln. S. S. de Finály

Hungarian procedure of morphine manufacture. J. Kabay. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 226–34(1930); cf. *C. A.* **24**, 3322.—Opium poppies are cut up and extd. to a jam-like pulp of about 0.4–0.8% morphine content. The washing liquid contains free H_2SO_3 which binds Ca and forms easily sol. alkaloid salts, prevents the further hydrolysis of chlorophyll and the fermentation or oxidation of the concd. ext. The mixt. of alkaloids is then sepd. and chlorophyll obtained as a secondary product. S. S. de Finály

New reaction for the identification of guaiacol carbonate. K. Száhlender. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 235–6(1930).—One-half g. guaiacol carbonate is mixed with 0.5 g. $ZnCl_2$ and heated in a dry test tube. A dark brown melt is formed with a very intense smell of guaiacol. The reaction may be brought about faster by using dried or melted $ZnCl_2$, since then it is not necessary to wait until the hygroscopic moisture evaps. S. S. de Finály

Evaluation of insulin. A. Stasiak and B. Zboray. *Magyar Gyógyszerésztud Társaság Értesitöje* **6**, 268–74(1930).—Cross tests of Marks (*C. A.* **23**, 5272) for the evaluation of insulin are modified by injecting into each animal 0.5 cc. soln. equal to 1 international standard. Three blood tests are taken for sugar detns. 1.5, 3 and 5 hrs. after injection. This method gives as exact data as that taking 5 blood tests. The sensitivity reaches 10% in 10-10 expt. series, 6 animals being used in each case. S. S. de F.

Early products in the history of drugs. J. Horváth. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 292–5(1930).—An address. S. S. de Finály

Comparative studies of camomile. P. Rom. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 296–9(1930).—The essential oil content of Hungarian camomile was detd. (1) by measuring the oil on the surface of the water during distn. as carried out in factory practice and adding the oil content of the cohobation water. (Results, 0.22 and 0.20%, resp.; total oil content, 0.42%); (2) by using the method prescribed by D. A. B. 6 (result, 0.49%). Earlier Hungarian data gave smaller contents since the oil content of the cohobation water was not detd. Some German samples contained 0.6–0.8%, a Russian one 0.58%. This latter was a yellow oil rather more sol. in water than that of Hungarian or German camomile. Examn. of 11 samples of Hungarian camomile of various regions showed oil contents of more than 0.4% for each. The sand content varied from 0.8 to 1.1% and the ash content from 10 to 11%. German samples contained 9–10% ash and 0.4–1.0% sand, Russian samples 11.5–15% ash and 2.7–5% sand. S. S. de Finály

Russian flores chamomillae. Á. Boros. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 300–6(1930).—Four samples of the Russian drug were examd. It may be distinguished from the Hungarian drug by the presence of *Agropyrum* (*Triticum*) *prostratum* L. and *Salsola tamariscina Pall.* and further of animal particles of *Amphicoma*

vulpes var. *hirta* Fabr. and *Dulaea Lichatschovi* Humm., which species do not occur on territories east of South Russia. S. S. DE FINÁLY

The evaluation of commercial Solanaceæ drugs. S. PERCSNÉ JÓNÁS. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 307–12(1930).—Folia belladonnae (I), radix belladonae (II), folia stramonii (III) and folia hyoscyami (IV) of Hungarian origin were examd. for alkaloid content according to Ph. Helvetica IV. I contained 0.18–0.20%, II 0.59–0.66%, III 0.21–0.33% and IV 0.11% alkaloids. Ash and sand contents were detd. by the method of U. S. National Formulary, p. 428. The values (in %) obtained for ash and sand contents, resp., were: I 16.99–17.04, 5.51–5.84; II 6.35–7.52, 0.68–0.76; III 18.67–23.80, 2.68–10.00; IV 22.04–22.23, 7.30–7.63. S. S. DE FINÁLY

Determination of alkaloids, especially the determination of morphine in preparations. E. SCHULEK. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 442–51(1930).—The indicators used for the titrimetric detn. of alkaloids should have p_H intervals agreeing with the p_H of the alkaloid soln. after titration. The morphine detn. method of Ph. Hung. 3 cannot be used in the case of some opium prepns. (*e. g.*, pantopone-like drugs). A micromethod was therefore worked out: Mix 0.605 g. of opium powder with some water, dil. to 6 cc. and filter through dry filter paper. Put 4 cc. of the filtrate into a 30-cc. bottle, add 0.20 cc. *N* NH_4OH and filter the ppt. through dry filter paper. Suck up a part of the filtrate with a micropipet, put into a 30-cc. Erlenmeyer flask and add 1 cc. purified EtOAc and 0.4 cc. *N* NH_4OH. Shake the mixt. for 15 min., again add 1 cc. EtOAc, shake and after 10 min. pour the EtOAc soln. on a filter paper. Now again add 1 cc. EtOAc, shake occasionally and pour first the EtOAc soln. and then the whole liquid on the filter, wash out the flask 3 times with 1 cc. water each time. Dissolve the cryst. morphine in 10 cc. boiled 0.02 *N* H_2SO_4 and titrate back the excess acid with 0.02 *N* NaOH. For the evaluation of tinctura opii evap. 5 g., dissolve the residue in 2–3 cc. water, add 0.2 cc. *N* NH_4OH and dil. to 6 cc. Filter the mixt., pour 5 cc. of filtrate into a 30-cc. Erlenmeyer flask, add 0.4 cc. *N* NH_4OH and det. the morphine as above. For the evaluation of extractum opii treat 0.3 g. ext. with a few drops of water and work up as above. The method of Buchbinder (U. S. Drug Control Laboratory) may well be used for the detn. of the morphine content of pulvis Doveri. S. S. DE FINÁLY

Water-soluble oils. K. GÖLLNER. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 452–9(1930).—Sulfonation expts. were made on olive, sesame, peanut, rape and neat's-foot oils and on pure white olein. Sulfonated neat's-foot oil gives the finest emulsion. It is suitable for cosmetic and skin-treating purposes. Cf. *C. A.* **25**, 557. S. S. DE FINÁLY

The adsorption capacity of bolus alba (kaolin) for different drugs. Z. CSIPKE. *Magyar Gyógyszerésztud. Társaság Értesitoje* **6**, 460–7(1930).—One to 35 g. of bolus alba was treated with 100 cc. of different solns. and shaken for 30 min. After sedimentation 10 cc. was examd. for its content of reagent remaining. 14.4–98.0 mg. methylene blue was adsorbed from a 1% soln.; 0–8.6 mg. $HgCl_2$ from a 1.30% soln.; 2.52–11.9 mg. I from a 50% alc. soln.; and 0–0.95 mg. nicotine from a 1% soln. No reagent was adsorbed from a 1% soln. of phenol or a 3% soln. of HCHO. Non-sterile bolus adsorbed 4.8 water vapor, sterilized bolus 7.2%. The ultraporosity of bolus is small since it has large but not many pores which bind only reagents having large mols. Sterilization often increased adsorptive power. S. S. DE FINÁLY

Researches on coffeinum natrium benzoicum. A. HÉRAY. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 468–73(1930).—Expts. showed that 2 mols. caffeine and 3 mols. Na benzoate form an addn. compd. The prepn. can be made by mixing 9.9 g. caffeine with 20 g. ether and 10 g. Na benzoate to pulp and evapg. the ether. The detn. of the caffeine and Na benzoate can be made as follows: Dissolve 0.30 g. coffeinum Na benzoicum in 5 g. distd. water, shake with 10 and 5 cc. $CHCl_3$, resp., for 5 min. and evap. the $CHCl_3$ soln. at a temp. not higher than 40°. The residue should weigh 0.15 g. Now add 2 cc. HCl to the caffeine-free aq. soln. and again shake with 2 5-cc. portions of $CHCl_3$ for 5 min. Add 30 cc. concd. alc. to the $CHCl_3$ ext. and titrate with 0.1 *N* NaOH with phenolphthalein as indicator. About 10.3–10.4 cc. should be used (1 cc. is equiv. to 0.0144 g. Na benzoate). S. S. DE FINÁLY

Examination of solutions of cresol soaps. I. LÉVOLT. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 474–80(1930).—Five samples of com. liquor cresoli saponatus and two samples of home-made liquors (one made according to Ph. Hung. 3 and the other according to D. A. B. 6) were examd. for cresol content and for the quality and quantity of the K soap contained. The fatty acid content and I-Br no. were detd. The presence of soap made of oleum jecoris was proved by the cholesterol reaction; of that made of sesame oil, by the furfural reaction, and finally the presence of naphthoic,

colophonic or linoleic acids by the $CuSO_4$ reaction of Charitschkov. The following method was used to det. cresol content: Dissolve 10 g. liquor in a mixt. of 100 cc. water and 30 cc. 10% KOH soln., add 30 cc. 10% $BaCl_2$ soln., shake the mixt. and dil. to 200 cc. Ba soap ppts. Filter 100 cc. of the purified upper part of soln. contg. alkali cresolates of 5 g. of the original liquor. Divide the filtrate into 2 parts, to each of them add 10 cc. dil. HCl and shake with 25 cc. petroleum ether. Evap. the solvent and dry the cresol for 30 min. at 100°. The av. of 2 detns. multiplied by 40 gives the % content of liquor in cresol. 42–50% was found in the samples. The soap examn. may be replaced by the detn. of the emulsifying capacity in the case of cresol soaps of naphthoic and colophonic acids. The cresol content was detd. by the method of Ph. Russ. 7 and by steam distn. with $CaCl_2$. The former method gave higher values, since colophonic acids are also distd. at the high temp. of the former method and increase the no. of cc. of NaOH used. S. S. DE FINÁLY

Present state of chemical evaluation of ergot (Secale cornutum). P. LIPTÁK. *Magyar Gyógyszerésztud. Társaság Értesitöje* 7, 9–23(1931).—The method of Keller-Fromme dets. other materials besides the sp. alkaloids. The method of Forst is exact but too complicated for drug-store practice. The D. A. B. method may give inexact data since Mg soaps may be formed and Na_2CO_3 may get into the ether, giving too high a value for alkaloids. Detns. based on the cornutine reaction of Keller-Fromme are inaccurate. A simple acid-no. detn. may give some information about the proper storage and age of ergot. S. S. DE FINÁLY

Determinations of the essential oil content of Hungarian coriandrum. S. PERCSNÉ JÓNÁS. *Magyar Gyógyszerésztud. Társaság Értesitöje* 7, 24–9(1931).—Hungarian coriandrum formerly contained more than 1% essential oil, but in the present harvests it has diminished to 0.6–0.3% content. The sp. gr. diminishes with the increase in oil content. Simple distn. of coriandrum with superheated steam gave higher values for essential oil content than did the method prescribed by D. A. B. 6. This may be explained by the very slight soly. of coriandrum oil in water. S. S. DE FINÁLY

Colloid-chemical methods in drug stores and laboratories. J. VONDRASEK. *Magyar Gyógyszerésztud. Társaság Értesitöje* 7, 59–72(1931).—An address. S. S. DE F.

Lycopin. L CHOLNOKY. *Magyar Gyógyszerésztud. Társaság Értesitöje* 7, 95–107 (1931).—Lycopin was extd. from *Tamus communis* and *Solanum dulcamara*. The crude product was purified by recrystn. from CS_2-petroleum ether. Combustion of this product gave 89.23–89.43% C and 10.63–10.84% H (theoretical compn. of $C_{40}H_{56}$, 89.48% C and 10.52% H). The mol. wt. detd. ebullioscopically in $CHCl_3$ was 526, 564 and 565 (theoretical, 536); that detd. cryoscopically in $CHBr_3$, 649, agreeing with Montanari's result obtained in benzene (cf. *Lestazione sperimentali agrarie italiane* 37, 909 (1904)). *Tamus* lycopin m. 170°, *Solanum* lycopin m. 174°. No secondary pigments could be found. The data in the botanical literature should be corrected, since the above plants contain lycopin only. S. S. DE FINÁLY

The volatility of nicotine. L. NAGY. *Magyar Gyógyszerésztud. Társaság Értesitoje* 7, 125–30(1931).—Expts. made with nicotinum puriss, Merck, showed that large losses of nicotine occur during distn. of the solns. Only about 10 cc. of nicotine solns. can be distd. without any appreciable losses in the case of solvents with high b. p. (as petroleum ether, alc.). About 100 cc. can be distd. without significant losses in the case of solvents with low b. p. (ether or a mixt. of ether and petroleum ether). The loss of nicotine by evapn. is greater from beakers than from Erlenmeyer flasks. About 0.6 mg. of pure nicotine is volatilized in 5 min. at 20–22°. S. S. DE FINÁLY

Senega roots adulterated by sarsaparilla. I. TEMESVÁRY. *Magyar Gyógyszerésztud. Társaság Értesitöje* 7, 131–4(1931).—An ext. of a com. sample of senega roots gave too brown a liquor. No green color was obtained on adding liquor ammonii anisatus but stronger darkening was observed. On examn. under a magnifying glass the sample was found to be adulterated with about 30–5% of sarsaparilla roots. Microscopic examn. showed the structural texture of sarsaparilla roots. The saponin content was detd. by dissolving defibrinized blood with ext. of sarsaparilla particles in physiol. NaCl soln. S. S. DE FINÁLY

Cascara. T. J. STARKER AND A. R. WILCOX. *Am. J. Pharm.* **103**, 73–97, 147–75 (1931).—A dissertation covering names, species, distribution, description, medicinal value, silvics of cascara, growth, collection and curing of the bark, safeguarding the future supply, the industry, est. of existing stand, prospects of future stands and artificial propagation of cascara. A bibliography is appended. W. G. GARSTER

The analysis of the more commonly used ointments of the British Pharmacopeia containing an inorganic principle as the active constituent. EDWIN H. BUNCE. *Indian*

Med. Gaz. **66**, 137–8(1931).—Methods are given for the detn. of the base in boric acid ointment, mercury ointment and other ointments that find general employment.
FREDERICK G. GERMUTH

The potentiometric titration of alkaloids with potassium iodomercurati. LOUIS MARICQ. *Bull. soc. chim. Belg.* **39**, 496–502(1930); cf. *C. A.* **24**, 1705, 4895.—The method previously reported for the titration of atropine, hyoscyamine, pilocarpine, cinchonine and sparteine is extended. The accuracy is as good as before. A. L. H.

Chemical composition of certain homeopathic tinctures. JOSEPH S. HEPBURN AND ALAN E. SMITH. *J. Am. Inst. Homeopathy* **23**, 1207–9(1930).—Detn. (as g. per 100 cc.) of (*A*) total solids, (*B*) ash, (*C*) total N, (*D*) ether ext. of certain homeopathic tinctures yielded the following results: *Dioscorea villosa A* 2.415, *B* 0.275, *C* 0.03670, *D* 0.082. *Hydrastis canadensis A* 1.408, *B* 0.275, *C* 0.03123, *D* 0.161. *Iberis amara A* 2.791, *B* 0.338, *C* 0.03992, *D* 0.164. *Sarracenia flava* (pitcher) *A* 1.927, *B* 0.340, *C* 0.02423, *D* 0.212. *Sarracenia minor* (pitcher) *A* 2.205, *B* 0.084, *C* 0.03123, *D* 0.313; (rhizome) *A* 3.150, *B* 0.095, *D* 0.098. *Sarracenia purpurea* (entire plant) *A* 0.855, *B* 0.255, *C* 0.00812, *D* 0.080. *Sarracenia rubra* (rhizome) *A* 4.280, *B* 0.075, *Sarracenia drummondii* (rhizome) *A* 1.930, *B* 0.045, *C* 0.02955, *D* 0.142. *Tectona grandis A* 0.908, *B* 0.233, *C* 0.01078, *D* 0.190. The presumptive test for the presence of alkaloids was pos. with the tinctures of *Hydrastis canadensis, Iberis amara, Sarracenia flava* pitcher and *S. rubra* rhizome, and neg. with the other tinctures. The alc. content ranged between 56.15 and 76.62% by vol., and between 49.89 and 69.73% by wt. J. S. H.

A comparison of assays of homeopathic tinctures made according to the American Homeopathic Pharmacopeia and the Homeopathic Pharmacopeia of the United States. (A. I. H.). RAYFORD E. WRIGHT AND JOHN A. BORNEMAN. *J. Am. Inst. Homeopathy* **24**, 61–70(1931).—Assays for alkaloids were made of tinctures of aconite, belladonna, gelsemium and nux vomica prepd. according to each of the 2 pharmacopeias. "The results of the assays indicate that tinctures made according to the Pharm. of the Am. Inst. of Homeopathy are actually 0.1 drug strength tinctures, and that they come up to the requirements of the U. S. Pharm. The results further indicate that the alkaloidal content of tinctures made according to the Am. Homeopathic Pharm. is variable, and that the assay of these tinctures (particularly Class I tinctures) is far below the assumed standard." JOSEPH S. HEPBURN

The determination of cineole in cajaput oil. A. RECLAIRE AND D. B. SPOELSTRA. *Ber. Afdeel. Handelsmuseum Ver. Koloniaal Inst.* No. **54**, 8 pp.(1930).—The method of Cocking (*Perfumery Essent. Oil Record* **18**, 165(1927); cf. *C. A.* **21**, 3252) was tested on known mixts. of turpentine oil, cineole, terpineol and citronella oil as well as on several samples of cajaput oil from the Dutch East Indies and found to be very useful. Up to 12.5% terpineol does not influence the results, but in case of a higher percentage a correction must be applied which can easily be calcd. from a table given. It is pointed out that the *o*-cresol used in the detn. must be freshly distd., otherwise the results are too low. J. C. JURRJENS

The preparation, composition and value of the sirup of iodotannate. Z. WEINSTOCK. *Rev. facultad cienc. quim.* (*Univ. La Plata*) **7**, Pt. 2, 83–95(1930).—There is no loss of I through volatilization in the prepn. of the sirup according to the formula given in the French Codex Supplement of 1920. Detn. of the I according to the Pharm. of Brazil is simple, rapid and exact as is the method of Ugarte. The entire I in the sirup is in the form of HI. It is therefore proposed that the sirup be replaced by a simple sirup of HI, thus eliminating the astringent tannins and their products of oxidation. The prepn. and essay methods of Machado and Sonol (cf. *C. A.* **24**, 5938) are considered unacceptable. B. S. LEVINE

Determination of moisture in tobacco by means of the hygrometer. N. M. MILOSLAVSKII AND A. I. PALANT. *Ukrainskii Khem. Zhur.* **5**, Tech. Pt., 117–25(1930).—Expts. show the absence of a simple relationship between the moisture in tobacco and that in the atm. This can be explained on the ground that the amt. of moisture in tobacco is detd. by its biol. condition and by the adsorptive capacity of the leaf itself. The hygrometer is not applicable to the measurement of moisture in tobacco, because the tobacco leaf is neither chemically nor biologically definite. S. L. MADORSKY

A new method of determining arsphenamine preparations. S. KEIMATSU AND K. WADA. *J. Pharm. Soc. Japan* **51**, 65–80(1931).—The sample (0.1–0.2 g.) was digested gently with K_2SO_4 (10 g.), $KClO_3$ (1 g.), water (10 cc.) and dil. H_2SO_4 (40 cc. of 1:1 vol.). On cooling, 0.5 cc. of 50% soln. of glucose was added and the mixt. digested again. When the soln. became clear it was titrated against 0.05 *N* $KBrO_3$ soln. with methyl orange as indicator. F. I. NAKAMURA

Oil of ambrette. R. N. *Parfums de France* **9**, 32–8(1931) (in French and Eng-

lish).—A review of the compn. of oil of ambrette and of the constitution of its principal constituents. A. PAPINEAU-COUTURE

The bitter orange and its products. GUIDO ROVESTI. *Rivista ital. essenze e profumi* **13**, 35–61(1931).—From the bitter-orange plant are produced the fluid ext., neroli oil, the concrete flower essence, bitter-orange water, petitgrain essence, petitgrain water and bitter-orange juice. The fluid ext. is produced by extg. the dry powd. peels with 60° alc. It is a limpid green-yellow liquid with bitter taste and pleasant odor, sol. in water and sugar sirups. Neroli oil is obtained together with bitter-orange water by distg. the flowers with steam. After distn. neroli oil is nearly colorless; with time it becomes red with a blue fluorescence. It keeps best in the dark. Ligurian neroli oil has d_{15} 0.8815–0.831, $[\alpha]$ 0.5–6.9, n_{20} 1.4710–1.4728, sapon. no. 28–67.5, esters as linalyl acetate 9.80–23.5%, soly. in 80° alc. 1–1.2 vols. Calabrian neroli oil has d_{15} 0.727–0.8755, $[\alpha]$ 5.30–6.48, n_{20} 1.4715–1.4720, sapon. no. 52–63, esters as linalyl acetate 17.64–21.56%, soly. in 80° alc. 1–1.2 vols. Sicilian neroli oil has d_{15} 0.860–0.924, $[\alpha]$ —2.54–5.65, n_{20} 1.4680–1.4740, sapon. no. 6–127. Neroli oil contains pinene I, camphene I, limonene, dipentene, paraffin, phenylethyl alc., linaloöl, nerol, terpineol, nerolidol, geraniol, farnesol, decylaldehyde, linalyl acetate, Me anthranylate, benzoates, palmitates, phenylacetates, acetates of different alcs., indole, phenylacetonitrile, a ketone analogous to jasmone, and acetic and palmitic acids. There are 35% of terpenes, 30% of linaloöl, 18% of linalyl acetate and 1% of Me anthranylate; the ketone gives the perfume. The yield in essential oil depends on the meteoric conditions during the collection of the flowers. The greatest is obtained on warm and dry days. Bitter-orange water is the by-product of the neroli oil distn. Its preservation is difficult as it is attacked by the microörganisms. The product has in suspension much neroli oil. The concrete flower essential oil is prepd. with petr. ether; it is of ointment consistency, having an agreeable odor and coffee color. The yield is 0.230–0.390%. The abs. essence is obtained from the flowers with 4 alc. washings, followed by cooling to —15°, filtration, and evapn. of the alc. *in vacuo*. The yield is 0.45–0.55%. It has d_{15} 0.9105–0.9228, $[\alpha]$ —0.74 to —5.48, n_{20} 1.4658–1.4729, sapon. no. 105–137.8, esters as linalyl acetate 36.7–48%, soly. in 95° alc. 1:1 by vol. Petitgrain essence is obtained by distg. the twigs of the bitter-orange tree. It is yellow, with the odor of the leaves, and contains pinene I, limonene, dipentene, camphene, linaloöl, geraniol, terpineol, linalyl acetate, geranyl acetate, Me anthranylate and furfural. The Ligurian product has d_{15} 0.890–0.900, $[\alpha]$—2.5 to —6.7, n_{20} 1.460–1.465, sapon. no. 115–170, esters as linalyl acetate 50–59%, soly. in 70° alc. 1 vol. in 2.5–3 vol. Calabrian petitgrain has d_{15} 0.8971, $[\alpha]$ —6.12, sapon. no. 214.60, esters as linalyl acetate 75.10%, soly. in 80° alc. 1 vol. in 1.3 vol. The yield is 250–280 g. per 100 kg. Petitgrain water is obtained during the distn. of the bitter-orange twigs. Bitter-orange juice is obtained from the ripe fruits; it is an intensely yellow liquid, the chem. compn. of which is not much different from that of sweet oranges, excepting for the bitter principles present. Its principal constituent is limonene (90–97%). Seven hundred g. is obtained per 100 kg. of fruits. The consts. are d. 0.852–0.856, $[\alpha]_{20}$ 88–96, n_{20} 1.473–1.475, sapon. no. about 9. R. SANSONE

Lemon and orange oils. E. BERTE. *Rivista ital. essenze e profumi* **13**, 75–7(1931).—A large no. of lemon oil samples sponge extd., had the consts. $[\alpha]_{15}$ 56° 0′ to 62° 0′, d_{15} 0.8560–0.8590, aldehydes as citral 4.50–6.00%, evapn. residue on the water bath 2.50–3.50%, n_{20} 1.474–1.4759. Sweet-orange oil had $[\alpha]_{15}$ 98° 0′ to 100°, d_{15} 0.8485–0.8500, evapn. residue 1.50–2.50%, n_{15} 1.473–1.475, soly. in 90° alc. 1:8. In Sicily there exist zones producing lemon oil with d_{15} lower than 0.8560. There is no lemon oil with d_{15} above 0.8600, except that from green fruits, having the low $[\alpha]_{15}$ 50° 0′ to 54° 0′, and a d_{15} sometimes above 0.8600. In 1930 were found lemon oils with $[\alpha]_{15}$ 67° 0′ and 70° 0′ and d_{15} under 0.855. Samples of directly prepd. and of distd. lemon oil, taken in 1931, had n_{15} 1.4740–1.467 and 1.4723–1.4745, d_{15} 0.8560–0.8581, citral 3.85–4.45%. In Nov., 1930, orange oil had the av. consts. $[\alpha]_{15}$ 98°, 20′ to 100°, 15′, d_{15} 0.8480–0.8498, residue on the water bath 1.50–2.65%. R. SANSONE

The essential oil of Satureia nepeta. L. PEPPINO LIOTTA. *Rivista ital. essenze e profumi* **13**, 93–4(1931).—The oil is a light caramel-brown, b. 214.5°, showing the absence of terpenic hydrocarbons. The soly. in 80° alc. confirmed the presence of considerable amts. of oxygenated products. The consts. were d_{17} 0.9335, $[\alpha]_D^{17}$ 109° 30′ soly. in 80° alc. 1:1, evapn. residue 4.82%, sapon. no. of residue 156. It contained 3% of pulegone. On boiling, the rotatory power rapidly decreases. With 50 min. of steam distn. all the oil is obtained from the plant. R. SANSONE

Microsublimation. A. CHALMETA. *Anales soc. españ. fis. quím.* **28**, 1407–19

(1930).—The convenience of microsublimation with caffeine and theobromine and with glucosides is discussed. E. M. SYMMES

Therapeutic solutions of soporific drugs. I. G. FARBENIND. A.-G. Brit. 338,985, Aug. 29, 1929. The method of prepg. aq. solns. of barbituric acids (described in Brit. 325,847; *C. A.* **24,** 4121), by use of a monoalkylated amide of a lower aliphatic acid, is applied to the prepn. of solns. of other soporific drugs such as the urethan of trichloroethyl alc., tribromoethyl alc. and bromodiethylacetamide. In examples given, *N*-ethylacetamide is used as a solubilizing agent.

Medicinal product. E. K. FREY and HEINRICH KRAUT. Ger. 518,292, Feb. 24, 1926. A medicine affecting the circulation of the blood and the action of the heart is prepd. from urine by freeing this from phosphates in the usual manner, adding uranyl acetate, filtering off the ppt., decompg. the ppt. with $(NH_4)_2HPO_4$ soln., filtering, removing phosphates from the filtrate, and then removing other salts by dialysis. The final filtrate may be purified by treatment with kaolin or like adsorbent followed by extn. of the adsorbent with $(NH_4)_2HPO_4$ soln. Alternatively, the adsorbent may be added to the dephosphatized urine. Examples are given.

Synthetic drugs. SCHERING-KAHLBAUM A.-G. Brit. 339,436, Oct. 31, 1929. Dihydroketo-1-alkylhalopyridine compds. are prepd. by treating 2-hydroxypyridine derivs. contg. a halogen atom in the 3- or 5-position (or both) with a simple alkylating agent or with one which contains a carboxy group (preferably in the presence of an acid-binding substance). Examples are given of the production of 1,2-dihydro-1-methyl-2-keto-5-iodopyridine, 1,2-dihydro-2-keto-5-bromopyridine-1-acetic acid, 1,2-dihydro-2-keto-3,5-dibromopyridine-1-acetic acid, 1,2-dihydro-2-keto-5-iodopyridine-1-acetic acid, 1,2-dihydro-2-keto-3,5-diiodopyridine-1-acetic acid and 2-hydroxy-3-bromo-5-iodopyridine. The products are sol. in water.

Synthetic drugs, etc. I. G. FARBENIND. A.-G. Brit. 339,359, Aug. 14, 1929. Basic compds. are prepd. by condensation of a satd. or unsatd. fatty acid contg. at least 10 C atoms, or an ester, chloride, amide or imido ester of such an acid (such as palmitic or oleic acid chlorides) with an aromatic primary or secondary amine having a side chain contg. tertiary N such as *p*-β-diethylaminoethoxyaniline, *p*-aminobenzoyldiethylaminoethanol and unsym. ethyl(or methyl)diethylaminoethyl-*p*-phenylenediamine.

Synthetic drugs. I. G. FARBENIND. A.-G. (Karl Streitwolf, Alfred Fehrle, Paul Fritzsche and Walter Herrmann, inventors). Ger. 518,208, June 16, 1929. Acylaminobenzenestibinic acids substituted in an *o*-position to the stibinic acid residue are prepd. by the customary processes. Thus, *m*- or *p*-acylaminoanilines substituted in the *o*-position to the NH_2 group, *e. g.*, with OH, OCH_3, CH_3, or halogen, and free from or contg. substituents, may be diazotized and then treated with an antimonite. Alternatively, *m*- or *p*-aminobenzenestibinic acids substituted in the *o*-position to the acid residue, and free from or contg. other substituents, may be acylated. Examples are given. The products are effective against diseases caused by trypanosomes, and may be administered *per os.*

Alkaloids. GEORG KNOTH. Ger. 516,283, Nov. 28, 1928. Addn. to 497,630. In obtaining volatile alkaloids by steam distn. by the methods of 497,630 (*C. A.* **24,** 4121), 500,294 (*C. A.* **25,** 560) and 500,998 (*C. A.* **24,** 4901), the distn. takes place at a steam pressure of above 2 atm. The process is especially applicable to nicotine, a mash of

tobacco being treated with a base such as NaOH to free the alkaloid before distn. In the example, the nicotine yield is increased from 0.16% to 2.12% by increasing the steam-distn. pressure from a pressure of 0.5 atm. to 5 atm.

Caffeine. KAFFEE-HANDELS. A.-G. Ger. 515,604, Oct. 23, 1923. Caffeine is extd. from raw coffee beans by moistening the beans and extg. with CCl_2H_2 at low temps.

Aqueous solutions of pure glucosides. G. RICHTER, LTD. Hung. 101,049, June 28, 1930. Glucosides sepd. from various plants or drugs are made water-sol. by adding salts or mixts. of cholic acid or its derivs.

Anthraquinone glucosides from drugs such as cascara and frangula. FRIEDRICH KAYSER and KARL SCHRANZ (to Winthrop Chemical Co.). U. S. 1,796,109, March 10. The water-sol. anthraquinone glucosides may be isolated in substantially pure form by a procedure involving the treatment of alc. or other exts. of the drugs with $Fe(OH)_3$, Mn hydroxide or Al hydroxide, thereby sepg. substantially all of the inert material, and subsequent drying of the solns. of the glucosides so isolated. The dried products, thus obtained in the form of fine leaflets, represent the substantially pure effective anthraquinone glucosides or mixt. of glucosides contained in the drugs. They are sol. in water with a slightly acid reaction, forming clear solns. generally of a brownish color, adaptable for use as purgative injections. Examples with details of treatment of cascara and frangula are given.

Betaine thiocyanate. I. G. FARBENIND. A.-G. Ger. 515,545, June 29, 1927. See Brit. 316, 693 (*C. A.* **24**, 1937).

1-(*m*-Aminophenyl)-2-methylamino-1-propanol. FIRMA E. MERCK. (Otto Dalmer and Max Oberlin, inventors). Ger. 518,212, May 16, 1929. The customary reduction methods are applied to 1-(*m*-nitrophenyl)-2-methylamino-1-propanone. Examples are given. The therapeutic properties of the product compare favorably with those of 1-phenyl-2-methylamino-1-propanol. Cf. *C. A.* **25**, 1264.

Basic tertiary alcohols. I. G. FARBENIND. A.-G. (Fritz Mietzsch, Josef Klarer and Hans Hahl, inventors). Ger. 518,211, Mar. 3, 1928. Compds. in which an amino or alkylamino group is linked by an aliphatic residue to an aromatic, hydroaromatic, or heterocyclic ring attached to a tertiary alc. group, are prepd. by the action of org Mg compds. on esters of cyclic carboxylic acids contg. an aminoalkyl or alkylaminoalkyl residue directly substituted in the nucleus or attached thereto through N or O. Thus, diphenyl-*p*-(diethylaminoethylamino) phenyl carbinol may be prepd. by treating ethyl *p*-diethylaminoethylaminobenzoate with the Grignard reagent from Mg and PhBr. Other examples are given also. The products are therapeutically useful and resemble ephedrine, hardenine and adrenaline in their effects.

Hydroxyanthraquinone derivatives. WALTHER STRAUB. Ger. 518,215, Feb. 6, 1929. The total content of hydroxyanthraquinone derivs., both free and combined, is extd. from drugs contg. them, *e. g.*, cortex frangulae, by means of a moist org. solvent not completely miscible with water, *e. g.*, Et_2O, $CHCl_3$ or C_2HCl_3. An example is given.

Gold compounds of succinimide. W. J. POPE. Brit. 338,506, July 19, 1929. *Therapeutic compds.* (various formulas of which are given) are prepd. by the interaction of chloroauric acid or Au hydroxide or a salt thereof, or fulminating gold, with succinimide in the presence of a base (suitably by heating in alc.). Compds. contg Br and the CNS radical also are mentioned.

Increasing the hypoglucemic action of insulin. G. RICHTER, LTD. Hung. 101,262, Jan. 28, 1930. Insulin is mixed with ext. of tonsilla.

Antirachitic preparation from yeast. GY. FEHÉR. Hung. 100,696, Aug. 4, 1927. Yeast is boiled with water and KOH or NaOH, then mixed with org. solvents. The upper phase is sepd., concd. and cooled. The fluffy crystals formed are recrystd. from alc., dried and irradiated in thin layers by a mercury lamp. The product is incorporated in cacao butter, mixed with sugar and pressed into tablets.

Vitamin-containing products. AAGE W. OWE. Ger. 472,814, Oct. 11, 1924. See Norw. 44,018 (*C. A.* **25**, 1336).

Liver esterase. HEINRICH KRAUT. Ger. 518,024, Jan. 5, 1928. Liver exts. are dialyzed against running water, whereby salts are removed and part of the albumin content is flocculated. The residual soln. is treated with an adsorbent, *e. g.*, kaolin or Al_2O_3, which adsorbs the remaining albumins. The purified solns. so obtained are suitable for therapeutic use. An example is given.

Hormones. SIGMUND FRÄNKEL. Austrian 121,007, Aug. 15, 1930. Details are given of the extn. of hormones from testicles by a process similar to that described in Brit. 292,962 (*C. A.* **23**, 1474–5). Cf. *C. A.* **24**, 3608.

Active lipoids. HENRI ISCOVESCO (to Health Products Corp.). U. S. 1,796,027, March 10. Dry pulverized organs such as testes, heart muscle, brain, adrenal cortex,

adrenal total, intestine, stomach, ovary, corpus luteum, red corpuscle, mammary gland, thymus, kidney, pancreas, total pituitary, placenta, prostate, lung, spleen, thyroid and liver are extd. with ether, $CHCl_3$ and alc. The solns. thus obtained are treated with acetone to effect pptn. of a lipoid-contg. material, and the ppt. is sepd. from the soln. and is treated successively with cold abs. alc., ether and $CHCl_3$ to effect purification if desired by soln. and subsequent repptn. with acetone. The starting material, such as cod livers, may be given a preliminary extn. with acetone. Various details and modifications of procedure are described.

Purifying olive oil or other vegetable oils. H. HATAKEYAMA and H. WATANABE. Brit. 339,011, Sept. 12, 1929. Remaining traces of fatty acids in partially purified oil are esterified with an aromatic alc. such as benzyl alc., phenylethyl alc., hydroxybenzyl alc. or cinnamic alc. to prepare a fully purified oil suitable for use as a *solvent for medicinal injections*.

Sterilization vessel for injection liquids. RUDOLF SCHMITZ. Ger. 515,947, Mar. 19, 1929.

Soaps, creams, etc. AUBERT C. J. PARENT. Fr. 695,218, Aug. 28, 1929. Esters of the *p*-aminobenzoic and phthalic series are incorporated in soaps, creams and other toilet prepns. Those esters classed as toxic are excluded.

Vermicidal composition. WM. E. WATERHOUSE. U. S. 1,796,070, March 10. A compn. suitable for killing worms consists of a water-sol. brown powd. material prepd. from powd. oil-extd. mowrah seeds by first extg. with water and then evapg. this soln. to dryness.

Improvement of tobacco and tobacco products. I. SCHÖN and I. HERCZEGH. Hung. 100,779, Sept. 24, 1929. Tobacco is moistened with a soln. contg. hygroscopic disinfectant and must-preventing agents, *e. g.*, 1000 g. water, 2.5 g. camphor, 1 g. saffron flour, 100 g. sirupus kaliumsulfoguajacolicus, 100 g. dild. alc. and 6 oz. $ZnSO_4$.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Manufacture of synthetic nitric acid and its salts. E. GUERIN. *Rev. chim. ind.* **39**, 258–62(1930).—A review. P. THOMASSET

The process of intensive production of sulfuric acid. E. OWSIANY. *Chem.-Ztg.* **55**, 76(1931).—App. is inserted between Glover towers and the first chamber, and between the first 2 chambers, mechanically to disperse, compress and expand the components, to ensure better contact. The consumption of pyrites was increased from 36.3 to 46.8 tons, and the H_2SO_4 made in the chambers decreased 11.8%, the balance being produced in the intensive mixers. E. M. SYMMES

The navy's sulfuric acid plant. H. M. COSTER. *U. S. Naval Inst. Proc.* **57**, 317–9(1931).—This plant, at the Naval Powder Factory, Indian Head, Md., is of the Grillo-Schröder type with Pt-$MgSO_4$ contact mass, having a rated capacity of 70 tons of 100% H_2SO_4 per 24 hrs. Several special features of the plant are described: (1) *a SO_2 recorder* operating on thermal-cond. principles, which enables the operator to supply gas of uniform SO_2 content to the converter; (2) a special *app. for detg. the strength of oleum* by cond. measurement; (3) a unique method for adding automatically the necessary water to the absorbing towers by admitting a mixt. of water and steam into a by-pass line in the circulation system. These features greatly reduce the cost of operation and simplify plant control. C. G. STORM

Problems of a Hungarian nitrate factory. T. SZAFFKA. *Technika* **10**, 155–60, 185–91, 247–52(1929).—Methods of nitrate manuf. in different countries are described. The Hungarian factory should avoid arc fixation of N_2, and should only use Ca cyanamide or synthetic NH_3 methods. S. S. DE FINÁLY

The manufacture of potassium metabisulfite. I. FERRAN. *Quim. e ind.* **7**, 277–9 (1930).—The manufacture of $K_2S_2O_5$ is described. Cost figures (in pesetas), in a plant making $Na_2S_2O_5$ at the same time, are 1027 kg. of 92% KOH 1129.7, 1422 kg. of 98% K_2CO_3 1707.6, 1138 kg. of 98% S 318.65, 247 kw. hrs. 74.1, water and light 10, 1400 kg. of Cardiff coal 112.0, salaries 135.3, 27 workmen 189, watchman 50, amortization 44 45, charges 71.7; metabisulfite obtained 3100 kg.; cost per 100 kg. of metabisulfite 117.4. S. L. B. ETHERTON

Outline of a potassium dichromate plant. VICTOR MAIDA. *Chimica e industria* **3**, 470–4, 510–3(1928).—$K_2Cr_2O_7$ is obtained by an oxidation of chromate or Cr ore in the presence of CaO and Na_2CO_3. The app. required and a plant sketch, with a calcn.

of cost for a daily production of 3000 kg. $K_2Cr_2O_7$, is given in detail. In Brazil $K_2Cr_2O_7$ can be produced for 876 reis per kg. R. D. BUMBACHER

The production of potassium sulfate from potassium chloride and sulfur dioxide. E. BRITZKE, S. VOLFKOVICH AND M. KAMENSKAYA. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 492–5(1930).—Expts. with a no. of catalytic agents to speed up the reaction between KCl and SO_2 in the presence of water vapor were made. At 500°, without a catalyst, only 4.5% of the KCl decompd. in 20 hrs. $CoSO_4$, $Co(NO_3)_2$, Fe_2O_3, $Fe(OH)_3$, Al_2O_3, CuO, burned pyrites and a series of slags contg. oxides of Al, Fe, Si, Ca and Na were tried. These were prepd. in the lab. or taken from com. plants. Max. effects were obtained from the slags contg. oxides of Fe, Al, Si and Na. The slag was ground to pass a sieve with 4900 holes per sq. cm., and 0.5% of the slag was added to the salt, which was ground to particles of 0.2–0.4 mm. diam. The yield of sulfate reached 98.2–99.8% in one hr. With 0.1% Fe_2O or 0.01% $Fe(OH)_3$ (of the wt. of KCl) the yield was 78–83% in 3.75 hrs. Burned pyrites gave a yield of 70% in 2 hrs. when 1% was used. With 0.5% CuO the yield reached 44% in 30 min. Various other slags were tried out, but without much improvement. J. S. JOFFE

Formation of carbon disulfide from hydrogen sulfide and coke. T. J. DRAKELEY AND W. J. BAKER. *J. Soc. Chem. Ind.* **49**, 475–8T(1930).—CS_2 in coal gas may be formed by decompn. of org. S compds. in the coal, or by reactions between C and free S derived from pyrites. When H_2S was passed over heated wood C or coke, an extended delay occurred before evolution of gas and CS_2 formation, caused by H_2S absorption by C. Small quantities of CS_2 were formed by the action of H_2S on wood C between 700° and 1000°, or on coke between 600° and 950°. In the tests the max. CS_2 yield was obtained at 2.4 l. of H_2S per hr. passed over. CS_2 was not obtained by the action of H_2S on coke from coal carbonized above 950°, nor was CS_2 obtained from H_2S and C at less than 500° or above 975°. Over 99% of CS_2 is decompd. on passing over wood C or coke at 850–1000°. E. M. SYMMES

Titanium oxide. RENÉ SPEITEL. *Rev. prod. chim.* **34**, 1–5, 40–4(1931).—A review. P. THOMASSET

The kinds of lime and their manipulation. F. EISEMANN. *Tonind.-Ztg.* **55**, 339–40 (1931). F. O. ANDEREGG

Quinquennial review of the mineral production of India for the years 1924 to 1928. Saltpeter. E. H. PASCOE. *Records Geol. Survey India* **64**, 287–92(1930).—The Gangetic plain is famous for its production of saltpeter which is extd. from the earth (1–29% salt). Wood ashes are added to decompose $Ca(NO_3)_2$. The liquors analyze NaCl 15.25, KNO_3 7.24, KCl 0.40, $MgCl_2$ 0.20, $CaCl_2$ 0.10, $CaSO_4$ 0.10 and $MgSO_4$ 0.10%. ALDEN H. EMERY

The solubility of salt, alone or in combination, in water and brines at temperatures below and above 100°. W. FROEHLICH. *Mitt. Kali-Forschungs-Anst.* **1929**, 37–66; *Chem. Zentr.* **1929**, II, 2485.—F. detd. the solubilities of KCl, NaCl and $MgSO_4$ in H_2O; of NaCl in the presence of KCl in H_2O; of $MgSO_4$ in H_2O contg. different quantities of $MgCl_2$; of NaCl in the presence of KCl in technical sylvinite extn. liquor and in van't Hoff's liquor Q 20; and of carnallite in the liquor Q 20. All detns. were made in an autoclave between 100° and 200°; in a few cases also some known figures at temps. below 100° were reëxamd. The values obtained are plotted in wt. %, and the curves are continued to the fusion temp., where the relation of salt to solvent becomes 100:0. For quantities of KCl + NaCl dissolved simultaneously in 100 g. soln. this line is absolutely straight, and at 722° it meets the m. p. of a mixt. contg. 1 mol. NaCl + 4 mols. KCl, according to the known fusion diagram of the mixt. of both chlorides, while from 120° downward NaCl shows an unvaried soly. of 16.4%. The most recent detns. of the soly. of $MgSO_4$ were confirmed, and deviating results obtained by F. or earlier investigators were traced to the presence of sediments consisting of labile hydrates; these hydrates hold an intermediate position between the stable hydrates $MgSO_4.6H_2O$ and $MgSO_4.H_2O$. G. SCHWOCH

The processing of sylvinite at temperatures above 100°. Dissolving, crystallizing and heat consumption. W. FROEHLICH AND E. RITTER. *Mitt. Kali-Forschungs-Anst.* **1929**, 67–89; *Chem. Zentr.* **1929**, II, 2485.—By means of the figures obtained for soly. in solns. satd. with NaCl and KCl (cf. preceding abstract) the sepn. of dissolved salt on cooling the soln. is calcd. The soly. of NaCl in a soln. satd. with KCl is greatest at 80°. Thus when such a soln. is cooled, NaCl + KCl is sepd. down to this temp.; NaCl is just dissolved again by solns. satd. at 150° and cooled to 20°, provided that the solns. are thoroughly agitated. Thus at a soln. temp. below 150°, KCl free from NaCl can be produced, while above 150° only KCl contg. NaCl is obtained. When the cooling is accompanied by evapn. of H_2O, as occurs especially in the vacuum cooling app.,

a mixt. of NaCl and KCl is obtained, which affects the results accordingly. In any case, a quantity of H_2O sufficient to keep the NaCl in soln. can be added. The kind and proportions of salts and liquor, as well as the H_2O to be added, are calcd. for a dissolving temp. of 100° and 200°, and for cooling with or without evapn. and with or without addn. of H_2O. These calcns. are carried out with reference to the practical conditions met with in the soln. of sylvinite. These conditions are discussed, together with thermotheroretical considerations on soln. at temps. above 100°. G. S.

Modern arrangements for extracting salt from the ocean in East Africa. Fr. Riedig. *Intern. Bergwirtsch. u. Bergtech.* **23**, 142–3(1930); *Kali* **24**, 271–3, 294–7(1930).—A brief description of the salt-extn. plant in the Italian colony Somaliland, claimed to be the largest ocean salt works in the world. E. I. S.

Commercial manufacture of hydrogen. E. Guerin. *Rev. chim. ind.* **39**, 354–7 (1930).—A short description is given of the methods in use. P. Thomasset

Mechanical mining and treatment of sulfur. J. B. Nealey. *Eng. Mining J.* **131**, 253–5(1931).—The practices at the Hoskins Mound and Bryanmound, Tex., plants of the Freeport Sulphur Co. are described. W. H. Boynton

Mica. J. H. Frydlender. *Rev. prod. chim.* **33**, 549–54, 584–6, 616–9, 654–5 (1930).—A review. P. Thomasset

Bleaching earths. O. Eckart. *Seifensieder-Ztg.* **58**, 132–3(1931).—Kaolins without bleaching properties yield their H_2O at 450–700°, while bleaching earths give off their H_2O rather uniformly between 200° and 900°; the nearer this curve comes to a straight line, the better is the bleaching power. A bleaching earth that has been acid treated follows the same rule, this indicating that bleaching earths possess a gel body and non-bleaching earths a cryst. body. By mixing 10 g. of oil with 10 g. of earth at room temp. bleaching earths showed an increase in temp. ("heat of wetting") of 4–13°, while non-bleaching earths showed a rise of 1°. P. Escher

Washing and bleaching clays of Azerbaidzhan (bentonites and floridines). S. A. Kovalevskii. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* 50 pp (1931). —Natural deposits are described. Bleaching clays as yet discovered require activation with H_2SO_4, but scarcity of acid prevents their immediate utilization. V. K.

Preparation of HCN (Gluud, Keller) **6**. Apparatus for mixing acids (Brit. pat. 338,440) **1**. HNO_3 production (Brit. pat. 338,497) **13**.

Chromic acid and sodium bisulfate. Harshaw Chemical Co. Brit. 338,938, July 30, 1929. Reaction between oleum and $Na_2Cr_2O_7$ is effected in an *app.* (details of which are described) so that molten products are produced directly which are then sepd. by centrifuging or settling; either or both products may be solidified by spraying or atomizing.

Nitric acid. N. Caro and A. R. Frank. Brit. 338,566, Aug. 13, 1929. NH_3 is oxidized with O or gases contg. O under normal pressure, resulting N oxides are compressed to "several atm." pressure in a turbo compressor and at this pressure are converted into HNO_3 by condensation and absorption. Cf. *C. A.* **24**, 5946.

Sulfuric acid. Willi Büsching. U. S. 1,795,995, March 10. See Fr. 673,105 (*C. A.* **24**, 2552).

Concentrating sulfuric acid. P. I. Kharitonov. Russ. appl. 58,870, Nov. 23, 1929. H_2SO_4 is concd. by hot vapors from the Kessler and Gaillard app. by first directing these gases contg. SO_2 and SO_3 into a superheater, where they are heated to 900–1200°, followed by their recycling through the concn. app. to conc. new portions of H_2SO_4 and to eliminate losses in S oxides by means of a continuous recycling of gases used for heating.

Material resistant to acids and alkalies. Kábelgyár, Ltd. Hung. 101,471, Jan.

24, 1930. S and Se are used together with animal hairs, paper sheets, waste cloth or materials, which in themselves are not resistant to acids and alkalies. The mixt. is pressed to forms, then heated under pressure to a temp. higher than the m. p. of S or of Se.

Alkali and alkaline earth metals. JAN H. DE BOER (to N.-V. Philips' Gloeilampenfabrieken). U. S. 1,797,131, March 17. See Brit. 323,718 (*C. A.* **24**, 3329).

Alkali and alkaline earth carbonates and chlorides. Soc. ANON. ALCALINA. Brit. 339,330, Aug. 1, 1929. See Belg. 358,292 (*C. A.* **24**, 925).

Alkali chromates. BOZEL-MALETRA (SOC. INDUSTRIELLE DE PRODUITS CHIM.). Fr. 37,257, Jan. 28, 1929. Addn. to 683,604. The amt. of alkali used is limited to the equiv. necessary for the formation of dichromate instead of chromate.

Alkali chromates. O. F. TARR (to Mutual Chemical Co. of America). Brit. 338,469, April 3, 1929. See U. S. 1,752,863 (*C. A.* **24**, 2553).

Alkali chromites. BOZEL-MALETRA (SOC. INDUSTRIELLE DE PRODUITS CHIM.). Fr. 37,256, Jan. 25, 1929. Addn. to 683,179 (*C. A.* **24**, 4593). Alkali chromites are prepd. by heating ores of Cr in the presence of alkalies in a reducing atm. or in a reducing medium, with or without pressure. The Fe obtained is sepd. by known means.

Alkali and alkaline earth metal cyanates. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Brit. 339,220, April 10, 1929. Urea is heated in the absence of solvents (suitably to 120–150°) with basic alkali metal compds. such as soda or potash or alkali hydrides (but excluding alkali hydroxides) or with alk. earth metal compds. such as CaO, $Ca(OH)_2$, or Ca carbide, hydride, amide or carbonate. NH_3 is evolved and recovered, and C_2H_2 also is formed when CaC_2 is used. Alk. earth metal cyanates obtained may be treated in aq. suspension or soln. with alkali metal compds. such as NaCl to produce alkali metal cyanates.

Cyanates and cyanamides. I. G. FARBENIND. A.-G. Brit. 339,371, Sept. 13, 1929. Cyanates and cyanamides are prepd. by heating urea with oxides or carbonates of bivalent metals such as the alk. earth metals (including Mg) and metals above Hg in the electromotive series such as Zn, Cd, Cu, Ni and Pb. At temps. between 130° and 400° mainly cyanates are formed, and at higher temps., cyanamides. NH_3 and CO_2 can be used instead of urea, and various modifications and details of procedure are described.

Cyanides and ferrocyanides. EMIL HENE. Ger. 515,850, Dec. 22, 1928. Alkali sulfates, CaO and H_2S are allowed to react to produce alkali hydrosulfides and $CaSO_4$. The latter is removed by filtration. The hydrosulfides are obtained by evapn. and heated with $C_2N_2(NH_2)_2$ to produce alkali thiocyanate and NH_3. The thiocyanate is heated with Fe or H or both to produce alkali cyanide and FeS or H_2S. The FeS reacts with the alkali cyanide to form ferrocyanide. Extn. with cold water removes the alkali cyanide, and extn. with hot water removes the ferrocyanide and alkali sulfide, which are sepd. by fractional crystn. The alkali sulfide is worked up to alkali sulfate.

Alkali metal hydrides. HERMANN FREUDENBERG and HARRY KLOEPFER (to Deutsche Gold- und Silber-Scheideanstlat vorm. Roessler). U. S. 1,796,265, March 10. Finely divided alkali metal is subjected to the action of H at temps. of about 180–300°.

Alkali phosphates; hydrogen chloride. METALLGES. A.-G. Ger. 518,203, Dec. 30, 1928. These are prepd. from alkali chlorides and P_2O_5 by introducing vaporized or solid P_2O_5 into a melt of alkali chloride into which steam is led.

Alkali sulfates. KALI-CHEMIE A.-G. Ger. 515,930, Jan. 18, 1927. In producing alkali sulfates from alkali chlorides by treating them with flue gases and steam, a 1% addn. of surface-active material such as clay, bauxite, SiO_2, etc., is present. Thus, the chlorides may be briquetted with rock salt, burned clay or fuller's earth before submission to the flue gas and steam.

Aluminates. MAX PASCHKE. Ger. 518,204, Feb. 15, 1927. Water-sol. aluminates are obtained as by-products in the manuf. of crude Fe, by adding Na compds., particularly Na_2CO_3, to the blast-furnace charge. The aluminates are extd. from the slag with hot water.

Metal salts by the double decomposition of salts with sulfates. I. G. FARBENIND. A.-G. (Otto Balz, inventor). Ger. 514,651, Nov. 15, 1927. HPO_3 or its salts are added. Gypsum is obtained as a by-product if Ca salts are used. Thus, $Ca(NO_3)_2$ soln. is treated with HPO_3 and hot 90% K_2SO_4 soln. The resulting KNO_3 soln. is readily sepd. from the coarse $CaSO_4$ produced. Other examples are given.

Metal carbonyls. I. G. FARBENIND. A.-G. Fr. 37,284, July 29, 1929. Addn. to 677,548 (*C. A.* **24**, 3329).—The process of the prior patent is carried out by mixing the primary material with liquids or molten masses and afterward treating with CO

to produce carbonyls under such conditions that the liquids or molten masses are in the gaseous phase or almost exclusively so during the reaction.

Aluminum chloride. I. G. FARBENIND. A.-G. Fr. 695,124, May 6, 1930. See Ger. 515,033 (*C. A.* **25**, 1644).

Ammonium nitrate. E. E. LIDER and I. E. KOROBCHANSKII. Russ. appl. 35,845, Nov. 22, 1928. NH_4NO_3 is prepd. from HNO_3 and NH_3 in a vacuum neutralizer connected by pipes successively with a column which acts as a trap for NH_3 and with a heat exchanger used for preheating HNO_3 passing into the neutralizer.

Ammonium nitrate. ODDA SMELTEVERK AKTIESELSKAPET and E. JOHNSON. Brit. 339,562, March 4, 1929. See Fr. 690,757 (*C. A.* **25**, 1342).

Ammonium sulfate. I. BÁLINT. Hung. 101,900, May 26, 1930. Na_2SO_4 is treated in soln. with NH_3 and CO_2. NH_3, however, is not regenerated from the mother liquor after the pptn. of $NaHCO_3$, but evapn. is continued and the soln. cooled until $(NH_4)_2SO_4$ is produced. To mother liquor contg. $(NH_4)_2SO_4$ may be added NH_4NO_3 in order to produce the double salt for use as fertilizer.

Borax. AMERICAN POTASH & CHEMICAL CORP. Fr. 37,316, Aug. 10, 1929. See Brit. 330,453 (*C. A.* **24**, 5949).

Carbon disulfide. ZAHN & Co. G. M. B. H. Fr. 37,206, July 10, 1929. Addn. to 672,766 (*C. A.* **24**, 2252). The CS_2 is cooled in the condenser to a temp. a little below its b. p. so that only a small quantity of H_2S is absorbed, which is afterward removed in known manner in the separator. Preferably, the gases liberated from the condenser are brought into a second condenser of the same kind but of smaller dimensions, from which the condensed materials are returned to the retort.

Separating calcium and magnesium chlorides from brines. WM. R. COLLINGS (to Dow Chemical Co.). U. S. 1,796,920, March 17. Tachydrite crystals are sepd. from a mother liquor having a higher proportion of $CaCl_2$ to $MgCl_2$ than the original soln.; the crystals are dissolved in a limited quantity of water with heating such that a soln. is produced from which on cooling to about 30° crystals of $MgCl_2$ hexahydrate will be pptd. and the filtrate remaining from the crystals will be of approx. 42.5–43° Bé. This filtrate retains the $CaCl_2$ in soln. at 30°.

Calcium-magnesium chloride. WM. R. COLLINGS and JOHN J. SHAFER (to Dow Chemical Co.). U. S. 1,796,885, March 17. A free-flowing non-caking mixt. of hydrated crystals of chlorides of Mg and Ca is pptd. as crystals of tachydrite and $CaCl_2$ dihydrate from a soln. satd. with the chlorides, and the crystals are superficially dehydrated to the point which avoids caking together. U. S. 1,796,886 relates to superficially dehydrating crystals after pptn. as crystals of the hydrated double chloride $MgCl_2.2CaCl_2$, $6H_2O$ and $CaCl_2$ dihydrate. Cf. *C. A.* **24**, 927.

Calcining lime or dolomite. W. VOSS and VULCAN-FEUERUNG A.-G. Brit. 339,105, Nov. 27, 1929. Water which is injected into a shaft kiln for calcining lime or dolomite is cooled nearly to the f. p. to prevent its conversion into steam before it contacts with the charge.

Hydrating lime. CLARENCE R. REX. U. S. 1,796,396, March 17. Various details are described for mixing a measured quantity of water with a measured quantity of quicklime, detg. the vol. of the water and the rate of supplying it to the lime and mixing to approx. a constant temp. during the reaction (the reaction being checked as complete by predetd. increase in vol.) so as to constitute a standardized com. operation.

Copper sulfate briquets. HUNGÁRIA MŰTRÁGYAGYÁR, LTD. Hung. 101,213, Feb. 1, 1928. $CuSO_4$ crystals of 0.25 to 5.00 mm. are formed by interrupted crystn. and briquets are formed from these. Generally no cementing matter is required since postcrystn. takes place after briquet formation. The briquets may be moistened with concd. mother liquor.

Hydrogen peroxide. ELEKTROCHEMISCHE WERKE-MÜNCHEN A.-G. Ger. 515,596, Sept 7, 1926. Solns. of H_2O_2 in caustic alkali are preserved and used in vessels of Al or its alloys.

Ferric phosphate. METALLGES. A.-G. (Freiherr Conway von Girsewald and Hans Weidmann, inventors). Ger. 518,315, May 30, 1929. The manuf. of $FePO_4$ by roasting ferro-phosphorus in air is accelerated by addn. of a catalyst, *e. g.*, NaCl or Na_2CO_3.

Iron carbonyl. I. G. FARBENIND. A.-G. (Alwin Mittasch and Carl Müller, inventors). Ger. 518,387, Dec. 16, 1924. Addn. to 499,296 (*C. A.* **24**, 4127). The method of Ger. 499,296 is extended to the use of Fe in non-spongy form. The preliminary reduction, if applied, should take place in a vessel sep. from that in which the carbonyl is prepd.

Liquefying nitrogen oxides. I. G. FARBENIND. A.-G. (Christoph Beck and Heinrich Diekmann, inventors). Ger. 518,386, Aug. 19, 1927. In sepg. N_2O_4 from gas

mixts., with or without other oxides of N, by liquefaction at atm. or raised pressure, the vapor pressure of the N_2O_4 is reduced by addn. of up to 10% of HNO_3 in liquid or vapor state. The added acid may first be enriched in oxides of N. If the gas mixt. is moist and contains O, the necessary acid may be formed *in situ*. Cf. *C. A.* **24**, 670.

Apparatus for adsorbing nitrogen oxides. V. I. MALYAREVSKII and V. V. PAPKOV. Russ. appl. 21,946, Nov. 28, 1927, 37,713 and 37,714, Dec. 28, 1928. Mechanical features.

Separation of salts of radium and barium. IVAN YA. BASHILOV. Ger. 515,681, July 24, 1925. See Russ. 5046 (*C. A.* **23**, 1059).

Separation of rubidium or cesium salts from alkali salts. KALI-FORSCHUNGS-ANSTALT G. M. B. H. (O. F. Kaselitz and Hans Grasshoff, inventors). Ger. 515,851, Mar. 22, 1930. Complete sepn. of technically pure Rb or Cs salts from alkali salts is effected by pptg. the Rb and Cs as alkali-Mg double phosphates. Thus, carnallite contg. 4% $RbCl_2$ is dissolved in water and treated with $Na_2HPO_4.12H_2O$. The ppt. is Rb-free $MgHPO_4.7H_2O$. The filtrate is treated with further $Na_2HPO_4.12H_2O$ and neutralized. The salt $MgRbPO_4.6H_2O$ is pptd., free from K. This ppt. is sepd. and dried. A further example is given.

Caustic soda; ammonium chloride. ALFRED MENTZEL. Ger. 510,093, Mar. 27, 1929. $NaHCO_3$ prepd. by the ammonia-soda process is mixed with C and treated with N at a high temp. The NaCN so obtained is treated with steam, NaOH and NH_3 being obtained. The latter is returned to the ammonia-soda process and ultimately recovered as NH_4Cl.

Sodium peroxide. HECTOR R. CARVETH (to Roessler & Hasslacher Chemical Co.). U. S. 1,796,241, March 10. Na_2O_2 is made by treating with O a pulverulent mixt. of Na_2O and not over 10% of finely divided metallic Na at a temp. of 200–350°. App. is described.

Titanium dioxide. JOSEPH BLUMENFELD (to Commercial Pigments Corp.). U. S. 1,795,467, March 10. A soln. of a Ti salt such as the sulfate is slowly added to water or to a soln. of lesser concn. while agitating, so that colloidal particles of TiO_2 are produced. Cf. *C. A.* **24**, 4175.

Verdigris. A. A. SVITZUIN. Russ. appl. 35,471, Nov. 17, 1928. Cu powder, obtained by pulverizing molten Cu, is treated with $Cu(OAc)_2$.

Treating silicates. F. JOURDAN. Brit. 339,028, Oct. 22, 1928. See Fr. 682,764 (*C. A.* **24**, 4594).

Treating greensand and other materials containing potassium. ARTHUR LAMBERT (to Cosmic Arts, Inc.). U. S. 1,797,002, March 17. The material is treated with an acid such as HCl or H_2SO_4 and with a basic Na compd. such as Na_2CO_3 to produce a substantially neutral soln. contg. K and Na salts, and the Na is then pptd. as $NaHCO_3$, the K salts being left in soln. Various modifications of procedure are described.

Treating kaolin, etc. R. ILLNER. Brit. 338,726, Dec. 13, 1928. Materials such as clay, kaolin, diatomaceous earth and sericite earth are improved by treating them in suspension with a slightly sol. salt such as $CaSO_4$ or $CaSO_3$ by stirring with such salts (which may be formed *in situ*). The material may also be treated with a bleaching agent or mixed with ultramarine or indanthrene blue for improvement of color. Brit. 338,730 describes stirring the material in acid suspension with $Na_2S_2O_4$, blowing with air, and adding $Ca(OH)_2$ with or without addn. of blue coloring substances.

Stabilizing solutions of per-compounds. ÖSTERREICHISCHE CHEM. WERKE G. M. B. H. Ger. 518,402, Sept. 22, 1926. See Austrian 119,036 (*C. A.* **25**, 385).

Activated carbon. SOC. DE RECHERCHES ET D'EXPLOITATIONS PÉTROLIFÈRES. Fr. 695,212, Aug. 27, 1929. Carbonaceous materials are heated with combustion gases or combustion residues and then activated with activating gases which are of such a compn. that they produce combustible gases. Activating gases which may be used are O, steam or CO_2, alone or mixed with Cl or HCl. Cf. *C. A.* **24**, 2558.

Reactivating carbon. METALLGES. A.-G. Brit. 338,500, June 8, 1928. Reactivation of C in lump form is effected en masse in a container such as an adsorber by preheating at least a portion of the material and then treating it with a gas or gas and vapor mixt. contg. less than 8% O. The preheating is then discontinued and the heating gas supplied at a temp. not substantially greater than 250° and preferably below 200° (thus effecting a localized reactivation zone formation, with travel of this zone in the direction of the gas flow). Cf. *C. A.* **24**, 1188.

Dispersion of carbon black in water. CHARLES R. PARK (to The Goodyear Tire and Rubber Co.). Can. 309,276, Mar. 10, 1931. Carbon black is exposed to the vapors of a material selected from a class comprising petroleum distillate and pine distillate to increase its dispersibility in later.

Bone black. T. L. WHEELER and J. B. CARPENTER (to Baugh & Sons Co.). Brit. 338,476, April 11, 1929. See Ger. 512,484 (*C. A.* 25, 1045).

Amorphous carbon from tar. ALEXANDER L. ULLRICH. U. S. 1,796,815, March 17. A solvent such as benzol is added to tar liquefied by heating, and to this mixt. there is added a relatively heavy hydrocarbon material such as fuel oil or kerosene in proportion to cause pptn. of the carbon particles of the mixt.; the ppt. is removed and treated with a solvent such as a light oil to remove sol. constituents, and the remaining substantially pure carbon is dried after being sepd. from the assocd. solvent.

Sulfur from sulfide ore. RAYMOND C. BENNER and ALFRED P. THOMPSON (to General Chemical Co.). U. S. 1,795,705, March 10. A mixt. of sulfide ore such as pyrites or pyrrhotite and a carbonaceous reducing agent such as coal is contacted in co-current flow with an oxidizing gas such as air, and the carbonaceous material is employed in sufficient quantity to effect reduction of the S to its elemental form. App. is described. Cf. *C. A.* 24, 2557.

Condensation products containing sulfur. I. G. FARBENIND. A.-G. Brit. 338,604, Aug. 24, 1929. Condensation products such as those formed from glycerol, ricinoleic acid and phthalic anhydride or similar initial materials, of oily to resin-like character, are heated with S or S compds. such as S monochloride (suitably at 160–70°) to produce products sol. in hydrocarbons and oils and suitable for use in the manuf. of stains, filling or priming compns., cements and varnishes, together with oils, resins, cellulose derivs., softening or plasticizing agents and siccatives. Several examples with details of procedure are given.

Sulfur and bentonite mixture suitable for use in making molded products. CARLETON ELLIS (to Ellis-Foster Co.). U. S. 1,795,364, March 10. A dry mixt. contg. S 90 and bentonite 10% is prepd. by grinding the materials with water and drying the dispersion thus formed at a temp. below the sintering point of S. Quicklime 1% may be added, and the compn. may be used with asphalt for waterproofing roofing, etc.

Artificial substances. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 37,496, Oct. 7, 1929 Addn. to 646,922 (*C. A.* 23, 2257). Artificial substances are prepd. by condensing in the presence of acid 1 mol. of an aromatic amine with almost 1 mol. of an aldehyde or the equiv. of an agent capable of liberating an aldehyde and converting the fusible resin thus formed, after elimination of acid, either alone or mixed with fillers, dyes, softening agents, etc., to the infusible state with hardening agents. Examples are given. Cf. *C. A.* 24, 5119; 25, 1046.

Preparing artificial masses. G. S. PETROV and A. K. PETROV. Russ. appl. 35,158, Nov. 12, 1928. Addn. to pat. 360. Artificial masses obtained according to pat. 360 are also prepd. from powdered substances such as are obtained in the treatment of cellulose with hydrating substances, *e. g.*, $ZnCl_2$, KSCN or caustics.

Plastic material. K. I. TARASOV. Russ. appl. 24,198, Feb. 25, 1928; 29,211, June 22, 1928. Addn. to pat. 10,398. Gypsum or a mixt. of gypsum with kaolin or chalk or with hydrocellulose or wood flour is mixed with casein which was preliminarily treated with condensation products of phenol and formalin, and the whole is treated according to pat. 10,398.

Plastic composition. STEFAN DISSMAIER. Austrian 121,553, Oct. 15, 1930. The compn. comprises wood pulp and comminuted leather waste, in approx. equal amts., and a water-insol. org. binder, *e. g.*, resin size. It may be used for coating masonry, protecting steam or water pipes, making buttons, etc.

Adhesive for bronze printing, etc. REINHOLD WOLFFRAM. Ger. 515,522, Mar. 20, 1929. A cement of sufficient adhesiveness for bronze printing, etc., is prepd. by incompletely fermenting a mixt. of dextrin and glucose with yeast and adding H_2O_2 or Na_2O_2. The fermentation is carried out at about 24°, and 0.3 to 1% NaOH and a small quantity of aq. castor-oil emulsion may be added. A conserving agent such as B_2ONa_2 may also be added.

Cement for uniting glasses of bi-focal spectacle lenses. A. BANISTER. Brit. 338,555, Aug. 20, 1929. A mixt. is used comprising cellulose acetate, glucose and acetone oil.

"Basing cement" for uniting lamp bulbs to bases. CLETUS C. VAN VOORHIS (to Westinghouse Lamp Co.). U. S. 1,795,746, March 10. A conducting substance such as graphite and an alc.-sol. gum such as shellac are used with $BaSO_4$, marble flour and a volatile solvent such as alc.

Decorating asbestos-cement slabs. HAWENTA-PLATTEN-GES. M. B. H. Ger. 477,210, July 16, 1927. See Brit. 327,871 (*C. A.* 24, 5129).

Wetting, etc., agents. H. TH. BÖHME A.-G. Fr. 37,134, June 18, 1929. Addn. to 671,456 (*C. A.* 24, 2257). Wetting, cleaning and impregnating agents for use in

the textile and other industries are made by sulfonating alcs. of high mol. wt. of the fatty acid or oleic acid series in the presence of anhyd. org. acids, their anhydrides or chlorides. Cf. *C. A.* **24**, 5952.

Wetting, etc., agents. I. G. FARBENIND. A.-G. Fr. 37,163, June 29, 1929. Addn. to 632,155. Non-aromatic hydrocarbons contg. more than 8 C atoms in the mol. and their derivs. are sulfonated with gaseous SO_2, preferably in the presence of an org. diluent. Examples are given.

Wetting, etc., preparations. I. G. FARBENIND. A.-G. Fr. 37,122, June 24, 1929. Addn. to 624,010. Prepns. having the properties of soaps to a very high degree and also a wetting and emulsifying power are composed of sulfonic acids of aliphatic, hydroaromatic, aromatic or heterocyclic compds. having the properties of soaps, or salts of these acids, and, besides, free sulfonic acids or other org. compds. not having in themselves pronounced soap properties. Thus, propylnaphthalene sulfonic acid is mixed with naphthalene sulfonic acid. Cf. *C. A.* **24**, 4906.

Wetting, foaming, emulsifying, etc., agents. I. G. FARBENIND. A.-G. Ger. 518,408, Jan. 31, 1929. These are prepd. (1) by the reaction of nuclearly halogenated aralkyl halides with aromatic or partly hydrogenated aromatic sulfonic acids during or after the sulfonation process, or (2) by condensing nuclearly halogenated aralkyl halides with aromatic or partly hydrogenated aromatic hydrocarbons and sulfonating the products. Thus, a mixt. of $C_{10}H_8$ and trichlorobenzyl chloride may be sulfonated, or first heated with $ZnCl_2$ and then sulfonated. Examples are given.

Detergent. ELECTRIC SMELTING & ALUMINUM CO. Brit. 339,355, Sept. 7, 1929. See U. S. 1,745,844 (*C. A.* **24**, 1712).

Detergents and lubricants containing fatty acid salts. P. SPENCE & SONS, LTD., and T. J. I. CRAIG. Brit. 338,919, May 21, 1929. A fatty acid such as stearic acid is treated with a soln. of alkali combined with a metal oxide sol. in the alkali such as that of Al or Zn, to produce products such as normal or basic double stearates, palmitates, oleates, etc., suitable for thickening lubricants, use with H_3BO_3 in polishing compns., etc.

Polishing agent. ARTHUR VAN DER BRUGGEN. Fr. 37,403, April 15, 1929. Addn. to 667,360 (*C. A.* **24**, 1191). The polishing agent is made by adding the $PhNO_2$ to the collodion and the acetone to the petroleum to facilitate the mixt. of the petroleum with the collodion in the presence of the $PhNO_2$.

Composition for cleaning and polishing silver. CINDERELLA RAISCH. U. S. 1,795,676, March 10. NaCl 8 oz., quinine chloride 1 oz., $MgSO_4$ 1.5 oz. and indigo 4 drops.

Treating magnesium articles to prevent tarnishing. EDWARD C. BURDICK (to Dow Chemical Co.). U. S. 1,795,473, March 10. The articles are subjected to the action of 10–30% H_2SO_4 soln. and then washed.

Bleaching powder. E. KREBS. Brit. 338,940, July 30, 1929. Lime is treated with Cl in a vertical-shelf absorber, and air is admitted in the bottom portion of the absorber while Cl is admitted at one or more higher points. Various details of the app. and its operation are described.

Trade-marking carbon paper. SAMUEL A. NEIDICH (to Neidich Process Co.). U. S. 1,796,956, March 17. Marking is effected by applying an acid material such as oleic acid capable of increasing the capacity of the web for absorption of waxy, oily transfer material, previous to application of the latter.

Carbon papers for manifolding or transfers. P. MEYER. Brit. 338,673, Oct. 11, 1929. Water-sol. soap and a water-sol. dye are used together (suitably with addn of a small proportion of oil) in prepg. coating compns.

Transfer material. W. S. LAWRENCE and KAUMAGRAPH CO. Brit. 338,611, Aug. 27, 1929. Transfers are formed with a paper base and a compn. contg. ethyl or benzyl cellulose, a resinous material such as cumar, a blown oil such as blown castor oil, and coloring material, and other substances such as Et lactate, tricresyl phosphate, Et abietate and glycol monoethyl ether also may be used in various mixts.

Duplicating printed or written matter. WILHELM RITZERFELD. U. S. 1,795,378, March 10. Reproduction from originals furnished with reverse characters is effected by making the original stencil on a sheet of paper which is thick and soft but has a smooth and dense surface, such as a paper contg. chalk, so that upon producing the stencil the characters are impressed deeply into the paper and form raised reversed characters on its back from which copies are made onto previously moistened copy sheets.

Stencil paper. DANIEL A. WILLIAMS (to A. B. Dick Co.). U. S. 1,795,461, March 10. Paper is coated with a compn. comprising a cellulose ester such as nitrocellulose

or cellulose acetate, glycerol (suitably in a quantity several times that of the cellulose ester), a relatively small proportion of a resin and a solvent which together form a soft stable product easily displaceable by impact of type. Cf. *C. A.* **24**, 4598.

Sound-record compositions. H. J. BILLINGS (to A. D. Little, Inc.). Brit. 339,335, July 17, 1929. Records are formed with a backing (suitably formed of sheets of paper alternating with sheets of fibrous material mixed with a thermoplastic binder), a record sheet (which may comprise shellac 48, graphite 25 and paper pulp 22% together with C black and rosin), and a thin coating comprising shellac which may be mixed with a filler and pigment. Various details of manuf. are described.

Combined sound and picture records. I. G. FARBENIND. A.-G. Brit. 338,817, Feb. 22, 1929. Sound and picture records are produced on a single film, and both records are then copied on a single film having a fine-grained colored emulsion of steep gradation (there being placed before the film bearing the sound record a screen of color complementary to that of the colored emulsion).

Light-diffusing panels. FRANK COLLINS (to Mutual-Sunset Lamp Mfg. Co.). U. S. 1,795,294, March 10. A fine-gauge wire screen fabric is immersed in a clear lacquer which solidifies on exposure to the air and forms a continuous transparent sheet encasing the fabric; there is then applied to one surface of this sheet a translucent color medium such as a colored lacquer compn. to form a design, and the entire opposite surface is treated with a translucent color medium contrasting in color with the design and providing a background.

Freezing-point depressant for use in automobile engine cooling systems, etc. JOHN W. ORELUP and OSCAR I. LEE. U. S. 1,795,883, March 10. Dispersed V oxide is used in compns. such as $CaCl_2$ solns. in order to protect metal parts of the cooling system from corrosion. Dispersed compds. of Th, Zr, Mo, Ta, Cb, Ti, W or U also may be used.

Dual-effect compression method and apparatus for producing carbon dioxide snow. JUSTUS C. GOOSMANN. U. S. 1,795,772, March 10. Various details of construction and operation are described.

Artificial snow. IGNAZ KREIDL. Austrian 120,806, Aug. 15, 1930. Artificial snow for decorative purposes is prepd. by pouring hot water on to a mixt. of a solid fatty acid and an alkali carbonate and beating the mass.

Apparatus (with agitators, screen and brush) for slaking lime. EDWIN J. SHAUT (to Baker Lime Machinery Co., Ltd.). U. S. 1,796,411, March 17.

Substitutes for sugars in industrial processes. I. G. FARBENIND. A.-G. (Otto Schmidt and Egon Meyer, inventors). Ger. 518,196, June 14, 1927. Water-sol. condensation products obtainable from aliphatic aldehydes are used as substitutes for glucose and other sugars in processes such as *printing or dressing textiles, filling transparent soaps, improving the elasticity of cements and adhesives, chrome tanning* and *coagulating latex*. Suitable condensation products may be obtained from CH_2O, glycolic aldehyde, glyoxal, or mixts. of CH_2O and AcH by treatment with a mild alk. reagent at a temp. between 0° and 100°. Examples are given.

Magnetic structures or cores. JACK C. CHASTON and JOHN P. JOHNS (to Western Elec. Co.). U. S. 1,795,639, March 10. Particles of magnetic material such as a Ni-Fe alloy contg. 80% Ni are insulated (suitably by CrO_3, Na silicate and talc) and the insulated particles are compressed to suitable form and then subjected to the action of a fluid such as moist air for a sufficient time to appreciably change the character of the insulating material as by swelling, and the resulting product is then heat treated.

Material for brake linings, clutch facings, etc. AURBORN L. HAGER and LON S. HAGER. U. S. 1,797,141, March 17. A fabric material is impregnated with a liquid mixt. comprising graphite, white lead and creosote. U. S. 1,797,142 relates to manuf of similar material by weaving a fabric and during the weaving impregnating it with a liquid mixt. comprising graphite, white lead and creosote, and heating the woven impregnated material to harden the white lead and graphite.

Fireproofing peat, etc. E. DYCKERHOFF. Brit. 339,067, Oct. 30, 1929. Peat or similar material is rendered substantially fireproof and non-smouldering by treatment with fireproofing solns. such as H_3PO_4 (suitably with heat and pressure), and the treated material is pressed and dried and may be formed into peat meal or shaped or pressed articles.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Glass. K. LOENBERG-HOLM. *Arch. Rec.* 68, No. 4, 327–58(1930).—The properties of glass as a building material are discussed. E. I. S.

Expansion measurements of several glasses by means of a self-registering apparatus. WILLI M. COHN. *J. Am. Ceram. Soc.* 14, 265–75(1931); cf. *C. A.* 24, 4434.—The app. registers photographically. Quartz glass is used as a control material. Slight variations which might escape visual observation can be detected. If results thus obtained are used a close regulation of annealing is made possible. C. H. KERR

Variations caused in the heating curves of glass by heat treatment. A. Q. TOOL AND C. G. EICHLIN. *J. Am. Ceram. Soc.* 14, 276–308(1931).—Variations in heating curves, due to previous heat treatment, are fully indicative of the nature of such treatment and they also bear a relation to changes in other characteristics of the glass. Differences in heating curves arise from differences in thermal properties, especially exothermic and endothermic effects. It is possible by rapid cooling to suppress the exothermic processes to a great extent and thus prep. the way for relatively large exothermic effects on subsequent heating. Annealing procedures may often be so manipulated that the resultant changes in certain properties, such as n, will cause a glass to meet certain standard specifications, when otherwise it would not. Also in *Bur. Standards J. Research* 6, 523–52(1931). C. H. K.

Devitrification. F. W. PRESTON. *Glass Ind.* 12, 1–3(1931).—During the slow cooling down of a soda-lime-silica glass melt, the first crystals which form are usually tridymite, wollastonite, or $Na_2O.3CaO.6SiO_2$, especially the last compd., according to Morey, *C. A.* 24, 5448, rather than cristobalite and wollastonite as stated by Dietzel, *C. A.* 24, 5447. Diagrams are given showing which cryst. phase may be expected if devitrification does occur in soda-lime-silica glass of any known compn. H. F. K.

Influence of water content of clays on their properties in drying and firing. V. P. ZUBCHANINOV AND D. I. SMIRNOV. *Trans. Ceram. Research Inst.* (Moscow) No. 24, 30–62(in German 62–5)(1930).—The authors investigated: (1) shrinkage and porosity of clays after drying to 110°; (2) shrinkage and porosity of bodies after firing to vitrified states; and (3) shrinkage and loss in wt. at different periods of drying and change taking place during these processes. Satisfactory results were obtained in measuring the vol. change, loss in wt. and vol. porosity of samples while drying and after firing to Seger Cones 010 and 10. Three periods can be distinguished during drying. In the first, shrinkage and loss of water proceed with const. velocity; shrinkage in vol. of the body remains equal to the vol. of the water evapd. In the second, the decrease in water (pore water) proceeds with changing velocity while the vol. of the clay body remains const. When drying in the air a certain part of the water remains in the clay. During the third period the hygroscopic water is removed by heating to 110°. The quantity of shrinkage water depends on the initial water content, but the quantities of the pore and hygroscopic water do not. The extent of shrinkage depends only on the quantity of the shrinkage water. The relation between the amt. of shrinkage and the amt. of pore water is a characteristic property of each clay. The relative content of pore water in kaolins is larger than in clays, although kaolin is more porous than clays. The water content of the paste has no influence on the change of the d. and size of the clay piece during firing. M. V. KONDOIDY

Ammonium hydroxide as a deflocculant for clay suspensions. ANGELO CASTIGLIONI. *Industria chimica* 5, 1465–8(1930).—NH_4OH (0.888), when added in proportions as low as 0.02% by wt. to clay suspensions, increases the fluidity markedly, thus making possible the use of much more concd. suspensions. In the manuf. of molded ceramic ware it permits the use of suspensions of d. 1.85 which remain as fluid as suspensions of d. 1.72 when Na_2SiO_3 is used as deflocculant. A. W. CONTIERI

Experiments in weathering plastic fireclays. STUART M. PHELPS AND C. G. DENNEY. *J. Am. Ceram. Soc.* 14, 319–24(1931).—Changes produced in weathering cannot be readily detected by the usual clay-testing methods. Either weathering changes are over-estd. or the present test methods are inadequate. C. H. KERR

High-alumina firebricks. J. F. HYSLOP. *Roy. Tech. Coll. Met. Club J.* (Glasgow) 1929–30, No. 7, 18–9.—For max. refractoriness, resistance to stresses and resistance to corrosion by slag it is desirable to have a high Al_2O_3 and thus a high mullite ($3\,Al_2O_3.2SiO_2$) content. Spalling tendency is greatly increased by the presence of free SiO_2. While a high Al_2O_3 content is desirable, refractories with 60% or more

Al_2O_3 tend to become more liable to spalling as the expansion coeff. increases with the Al_2O_3 content. Because of the cost it is economical only in extreme cases to employ materials with high Al_2O_3 derived from diaspore, bauxite, cyanite or corundum. Properly made bricks from clays approaching 45% Al_2O_3 show high resistance to temp., as well as to corrosion and spalling. H. C. PARISH

Oldenburg clinker. WERNER DOHM. *Ziegelwelt* **61**, 571–4(1930).—Clinker differs from the ordinary brick in that it has been burned to a sintering point. To make clinker it is essential to use a clay rich in alkali and Fe_2O_3, but low in $CaCO_3$ and $MgCO_3$. A suitable clay analyzed: SiO_2 70.22, Al_2O_3 13.67, Fe_2O_3 6.80, CaO trace, MgO 1.30, K_2O and Na_2O 3.37, ignition loss 5.30 per cent. The clinker is commonly 22 × 10.5 × 5 cm. in size. Well-burned units are very dense, hard, tough and very satisfactory as paving and heavy building materials. H. F. KRIEGE

Correlation of the crystal structures and hardness of nitrided cases. O. E. HARDER AND GEORGE B. TODD. *Fuels & Furnaces* **9**, 295–7(1931); *Steel* **88**, 51–2. M. S.

Recent developments in the German ceramic industry. FELIX SPRINGER. *Bull. Am. Ceram. Soc.* **10**, 85–7(1931). C. H. KERR

Moisture expansion of glazes and other ceramic finishes. H. G. SCHURECHT AND G. R. POLE. *J. Am. Ceram. Soc.* **14**, 313–6; *Bur. Standards J. Research* **6**, 457–63 (1931); cf. *C. A.* **23**, 5554; **24**, 3871.—Some glazes show expansion, due to moisture, similar to that of the body. This means less liability to crazing when the ware is exposed to moisture. Artificial weathering treatment (exposure to steam at 150 lb. sq. in. for 1 hr.) caused an av. expansion, in lustrous glazes, of 0.004%; in mat glazes, 0.011%; in vitreous slip finishes, 0.005%; and in porous slip finishes, 0.033%. The moisture expansion of one of the mat glazes was 30% of the av. for a ceramic body with approx. 12% absorption. C. H. KERR

Electrical porcelain. H. M. KRANER. *Elec. Eng.* **50**, 209–11(1931).—American and European samples of standard insulating porcelains show similar characteristics in the finished product despite the variations in raw materials and mfg. processes. A table gives the modulus of rupture of ceramic materials including tests on quenched samples. W. H. BOYNTON

Comparison of bodies containing blended feldspars and one-mine feldspar of similar composition. C. W. PARMELEE AND C. R. AMBERG. *J. Am. Ceram. Soc.* **14**, 309–12 (1931).—Tests were made with an elec. porcelain body mixt. Since it is impossible to consider more than 2 factors in the blending of 2 materials, all but 2 factors should be uniform and this can be obtained only from one-mine materials. C. H. KERR

Stoneware in the chemical industry. F. WEINREB. *Chemistry and Industry* **50**, 213–4(1931).—Because of its strength, its machinability and resistance to acids and bases, *steatite* may in the future find more application in the chem. industry. Its high expansion coeff. limits its use. At present the ceramic industry has not succeeded in making a material combining d. with the ability to resist high temps. The porosity of stoneware has caused a considerable monetary loss from absorption of precious metals in electrolytic baths. A sillimanite mass can be used for making very dense vessels with an absorption of only 0.01%. H. C. PARISH

Economy in selection and design of chemical stoneware. J. M. W. CHAMBERLAIN. K. D. JACOB *Chem. Met. Eng.* **38**, 142–4(1931).

Manufacture of stoneware. T. W. TALWALKER *J. Indian Ceram. Soc.* **2**, 21–27, 65–74, 83–97, 130–43(1930).—Expts. were carried out in a factory mfg. acid jars. Economics of the industry and materials and processes are discussed. T. concludes that it is possible to make a low-temp., highly resistant body, by using frit in the body, and using a fritted glaze high in resistant materials such as ZnO, B_2O_3 and ZrO_2. JOHN M. LADINO

The use of refractory natural stone. H. KALPERS. *Zentr. Europ. Giesserei-Ztg.* **2**, No. 2, 1–3; *Chem. Zentr.* **1929**, II, 1196; *Giesserei* **17**, 1045–7(1930).—The refractory natural brick of Hugo Schlenkermann (cf. O. Beckmann, *Giesserei-Ztg.* **25**, 156–9) contains SiO_2 90.59, Al_2O_3 + TiO_2 6.85, Fe_2O_3 0.20, MgO 0.15, K_2O 0.22 and Na_2O 0.90%. The loss on ignition is 1.10%. The refractoriness of these bricks varies from cone 35 to 36. The behavior of these bricks under pressure was tested with the app. constructed by the Chem. Lab. für Tonindustrie. The bricks were also examd. with regard to their behavior toward changes in temp. and their ability to keep their vol. Their fitness for cupola and reverberatory furnaces is emphasized. Hollow spaces and gaps between the bricks are filled with a special stamped material. G. SCHWOCH

Refractory pastes for use in laboratories. MANUEL FELIU. *Quim. e ind.* **7**, 280 (1930).—F. mentions various pastes and recommends the Pythagoras paste made by Haldenwanger, porcelain manufacturers, in Spandau, Berlin. It is a mixt. of kaolin,

Al_2O_3 and feldspar. The kaolin decomposes into Al_2O_3 and a glass which, with the Al_2O_3, gives sillimanite. Tubes made of this paste withstand all temps. up to 1700° and above. The paste is used in protecting tubes for thermoelec. elements and such tubes are impermeable to gases even above 1700°. S. L. B. ETHERTON

Special refractories for metallurgical research. DONALD TURNER. *Trans. Faraday Soc.* **27**, 112–24(1931).—A description of the refractory materials developed for use in various investigations at the National Phys. Lab., and the methods of production employed. CURTIS L. WILSON

Investigations on the slagging of refractory materials. IV. Investigations on the corrosive power and the constitution of iron-smelting slags. HERMANN SALMANG AND FRIEDRICH SCHICK. *Arch. Eisenhüttenw.* **4**, 299–316(1930); cf. *C. A.* **22**, 3272.—The corrosive power of the oxides present in Fe-smelting slags (CaO, FeO, MgO, MnO, Fe_2O_3, Mn_2O_3, Al_2O_3, TiO_2, SiO_2, P_2O_5 and also K_2O, Na_2O, CaS, and CaF_2) on fireclay (at 1410° and 1500°) and on sillimanite (at 1580°) was detd. synthetic binary, ternary and quarternary slags being prepd. from these oxides. In the fusions, CaO is found to be the strongest oxide, FeO, MnO and MgO following next in strength. Oxides of the type MO (M = metal) react as bases, while those of the type M_2O_3 react as acids. Thus, the latter oxides do not attack fireclay and check the attack of bases. In silicate fusions Fe_2O_3 is stable up to 1580°, while Mn_2O_3 decomposes at 1500°. Contrary to expectation from the heats of formation of the silicates of the corresponding oxides, the alkali oxides behave as weak acids at these high temps., while the alk. earth oxides act as strong bases. P_2O_5 checks the attack of bases, and when present in large amts. in the slag, the excess attacks strongly (especially at the higher temps.). The attack on these refractories increases about 50% from 1410° to 1500° and from 1500° to 1580°, from which it is concluded that the dissocn. of the melt increases in the same ratio. J. BALOZIAN

Preparation of chamotte-free fireproof and acidproof objects. P. P. BUDNIKOV, S. N. ZHIKHAREVICH AND I. G. SHAKHNOVICH. *Ukrainskii Khem. Zhur.* **5**, Tech. Pt., 93–103(in German 104)(1930).—Chamotte-free fireproof and acidproof objects can be prepd. by using artificially prepd. lean lime to the extent of 85–93% of the mixt. The process lends itself easily to mech. treatment. For the dehydration of lime a drying drum is required working on the counter-current principle. To make brick by this process a pressure of 250 atm. is required. This method eliminates prepg. the mixt before shaping the objects and drying before firing. S. L. MADORSKY

Standards and tests for coated abrasives. E. C. SCHACHT. *Am. Soc. Mech. Eng.*, Advance Paper, Oct. 16–17, 1930, 7 pp. E. I. S.

Cr-plated molds (STOCKFISCH) **4.** Coating for lamp bulbs (Can. pat. 309,250) **4.**

Apparatus for feeding mold charges of molten glass. GEORGE E. HOWARD (to Hartford-Empire Co.). U. S. 1,796,929, March 17. Structural features.

Device for withdrawing or delivering measured quantities of fused glass. ADOLF SCHILLER. Ger. 518,236, July 29, 1926.

Glass leer of the muffle type with an endless conveyor for carrying articles through it. WM. A. MORTON (to Amsler-Morton Co.). U. S. reissue 18,004, March 17. Reissue of original pat. No. 1,684,239 (*C. A.* **22**, 4218).

Glass-gathering apparatus. GEORGE E. HOWARD (to Hartford-Empire Co.). U. S. 1,797,206, March 17. Structural features.

Glass furnace and associated apparatus for making spun glass. LOUIS MATHIEU. U. S. 1,796,571, March 17 Structural features.

Apparatus for pouring molten glass into sheets. N.-V. MAATSCHAPPIJ TOT BEHEER EN EXPLOITATIE VAN OCTROOIEN. Fr. 37,359, Aug. 22, 1929. Addn. to 579,444

Furnace and associated apparatus for sheet-glass manufacture. SAMUEL C. CRIPE (to Libbey-Owens-Ford Glass Co.). U. S. 1,795,933, March 10. Structural features.

Apparatus for sheet-glass manufacture. JOHN L. DRAKE (to Libbey-Owens-Ford Glass Co.). U. S. 1,796,836, March 17. Structural features.

Apparatus for drawing sheet glass. WERT FRENCH (to Libbey-Owens-Ford Glass Co.). U. S. 1,796,943, March 10. Structural features.

Apparatus for manufacture of sheet glass by rolling. CHANCE BROS & CO., LTD., and A. L. FORSTER. Brit. 339,535, Jan. 23, 1930. Structural features.

Rolling glass sheets. Y. BRANCART. Brit. 338,477, April 20, 1929. Various details of procedure are described for insulating glass sheets from their receiving surfaces during rolling, by a gaseous cushion of combustion products.

Apparatus for plate-glass manufacture (roller construction). Y. BRANCART. Brit. 339,546, Feb. 14, 1929.

Pressed molded glassware. CHANCE BROS. & CO., LTD., and R. BROWN. Brit. 339,484, Dec. 3, 1929. Various mech. details of manuf. are described.

Marbled or multicolored glassware. C. LOCREILLE. Brit. 339,583, April 9, 1929. Masses of glasses are prepd. which are of different colors but of substantially the same compn.; they are melted in sep. pots or furnaces, and one of the glasses is treated with sep. quantities of the others. Various details of temps., etc., are given.

Cooling oven for glass. N.-V. MAATSCHAPPIJ TOT BEHEER EN EXPLOITATIE VAN OCTROOIEN. Ger. 516,193, June 15, 1929. Addn. to 476,927 (*C. A.* **23**, 3785).

Blowing and molding articles of fused silica. QUARTZ ET SILICE. Brit. 338,456–7, April 16, and 17, 1929. Mech. features.

Blown articles of fused silica. QUARTZ ET SILICE. Brit. 339,197, Oct. 30, 1929. Various details of manuf. are described.

Fusing together grooved sections of fused quartz, etc. LESLIE SAMPLE (to Thermal Syndicate, Ltd.). U. S. 1,796,401, March 17. Mech. features.

Uniting glass sheets with non-brittle transparent material. LIBBEY-OWENS GLASS CO. Brit. 338,988, Aug. 30, 1929. The surface of the intermediate sheet is roughened by spraying onto it a discontinuous layer of an adhesive material such as a mixt. of equal parts of an ester of phthalic acid such as dibutyl phthalate and of a polyglycol deriv. such as monoethyl ether or diethyl glycol. The inner surfaces of the glass sheets may be coated with a soln. of a cellulose deriv. and a synthetic resin, with or without a plasticizer, and may also be coated with adhesive, and the sheets are united under pressure while heated. Cf. *C. A.* **25**, 1962.

Reënforced glass. SOC. DES USINES CHIMIQUES RHONE-POULENC. Fr. 37,119, June 22, 1929. Addn. to 658,563 (*C. A.* **23**, 5291). The compound sheets of glass are heated without pressure to a temp. above the ordinary after removal from the bath of plastifying material.

Bricks. FRANCO BANDINI. Austrian 120,972, Aug. 15, 1930. Clay contg. at least 20% of water is warmed to about 95° and molded in a press maintained at the same temp. The bricks are dried at once in a moist atm. in an oven in which the temp. is initially the same as that of the bricks, but is gradually raised.

Bricks and mortar from magnesite or magnesia. MAGNEZITIPAR, LTD. Hung. 101,353, July 20, 1929. Overheated natural or artificial magnesia is powdered, particles smaller than 0.1 mm. are removed, and 5 to 35% of a substance rich in Al matter, *e. g.*, bauxite, corundum or corundum slag, is added. Bricks made of this mixt. are very refractory.

Tunnel kiln for bricks. VOJTĚCH LAŠTOVIČKA. Austrian 120,977, Aug. 15, 1930.

Extracting clay and other aluminous raw materials with acids. OSKAR JONAS, KURT WEGER and GOTTHARD TREBITZ (to I. G. Farbenind. A.-G.). U. S. 1,796,107, March 10. Material such as calcined clay is treated with acid such as HCl in large batches *in situ*. The reaction is started by flooding the charge with acid washing water from a previous operation and adding in preheated condition a small portion of the total acid required for the reaction, with further acid addn. to obtain a strong alumina soln., simultaneous withdrawal of satd. ext. to maintain a const. level of liquid on the charge and maintenance of a min. temp. of 105° in the reaction zone by the heat of reaction.

Ceramic noble metal preparations. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORMALS ROESSLER (Franz Schelling, inventor). Ger. 515,588, Oct. 14, 1927. Noble metal prepns. for decorating and coloring ceramic ware are obtained from dispersions of the metal or its compds. in cellulose derivs., in the presence or absence of solvent and flux. Thus, a 30% $AuCl_3$ soln. in alc. is stirred into a soln. of nitrocellulose in ethyl glycol and cyclohexanone. Several addnl. examples are given. The method is stated to be applicable to all metals.

Apparatus for dipping pottery or earthenware into glazing or coloring liquid. G. WADE & SON, LTD., and G. A. WADE. Brit. 339,395, Sept. 27, 1929. Structural features.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

A new shaft-kiln cement plant. HORST LAEGER. *Tonind.-Ztg.* **55**, 322–5(1931).—The shaft kiln with rotating grate recently erected in Ankara (Angora) is described. F. O. ANDEREGG

The enumeration of French cement plants. PAUL RAZOUS. *Ciment* **36**, 13–8, 59–61(1931).—A list is given of the different companies and plants in France making the following cements: natural, Roman, artificial (portland), high-early-strength, alumina, slag (with lime), grappier (from flint nodules), iron (70% portland with 30% granulated blast-furnace slag) and blast-furnace (containing less clinker than iron cement).
F. O. ANDEREGG

Modern cement burning. HEINRICH LUFTSCHITZ. *Tonind.-Ztg.* **55**, 184–6(1931).—A description is given of the Schröder kiln, in which the dry, powd. raw material falls through a shaft heated by powd. coal falling through an outer annular space (Ger. pat., 495,001, *C. A.* **24**, 3340). The Rigby patent (Ger. pat., 478,632, *C. A.* **23**, 4792) for spraying slurry into a kiln is also described. F. O. ANDEREGG

Cement synthesis in the four-component parallelogram and the degree of lime saturation according to Kühl. M. SPINDEL. *Tonind.-Ztg.* **55**, 305–7(1931).—The parallelogram for the 4 components CaO, SiO_2, Al_2O_3 and Fe_2O_3 may also be conveniently used for Kühl's degree of lime satn. HANS KÜHL. *Ibid* 320–2.—K. prefers his quotient based on mol. wts. M. SPINDEL; HANS KÜHL. *Ibid* 366–8.—More polemics.
F. O. ANDEREGG

To secure cement of uniform quality. W. SACH. *Tonind.-Ztg.* **55**, 291–3(1931).—Proper feeding, weighing and mixing, obtained with suitable automatic equipment, are useful in maintaining a uniform quality. F. O. ANDEREGG

High-early-strength cements and their increases in strength. P. MAY. *Tonind.-Ztg.* **55**, 171–3(1931).—Generally increasing strengths have been encountered up to 5 years, with occasional temporary retrogressions. F. O. ANDEREGG

German specifications for alumina cement. HUGO VIERHELLER. *Tonind.-Ztg.* **55**, 325–6(1931).—Fineness is to be not more than 2% on the 75- and not more than 15% on the 180-mesh sieve. Tests are to be made at 15° to 20°. Specimens are to be stored 24 hrs. in a damp closet and then under wet cloths. The min. strengths are to be: compression 400, 500, 600 and tensile 25, 30 and 45 kg. per sq. cm. after 24 hrs.' 28 days' wet and 28 days' combined storage, resp. F. O. ANDEREGG

Tentative specification for high-alumina cements. *Structural Eng.* **8**, No. 10, 369–73(1930). E. I. S.

Asbestos-cement pipes—their production, characteristics and uses. A. SCHOTTAK. *Gas u. Wasserfach* **74**, 293–7(1931).—Up to the present, the use of asbestos-cement pipes has been limited because of their small production. These pipes are made by mixing 1 part of ground asbestos with 5 parts of cement and sufficient water to give a thin grout. This grout is then collected in a 0.2-mm. layer on an endless belt which transfers the material to an iron roll of the internal diam. of the desired pipe. This roll presses out the surplus water, and when the coating becomes heavy enough the roll is removed and a new roll substituted. The tube is removed from the iron roll while still soft and placed on a wooden mandrel of similar size. The pipe is then allowed to harden in a damp, fairly warm room. These pipes have found use for flue pipes, house-drain lines, etc. Some difficulties have been encountered with their use for gas and water, but these difficulties are being solved and the pipe can be used up to moderate water pressures. The pipes can be sawed, burned or bored with ordinary wood-working tools. They may be dropped 6 ft. on a concrete floor without damage. Breaking strengths, etc., are given, as well as hydraulic tests. Joints are described and illustrated. The pipe is said to cost about $^1/_3$ less than cast-iron or steel pipe. R. W. RYAN

Rapid determination of magnesia in portland cement. CH. ROGOZINSKI. *Tonind. Ztg.* **55**, 355–6(1931).—Remove silica and add *N* NaOH till a ppt. forms and the supernatant liquor is clear. Filter into an excess of 0.2 *N* HCl, and titrate the excess with 0.2 *N* NaOH with phenolphthalein indicator. F. O. ANDEREGG

Zeolites and hydraulic cements. HENRI LAFUMA. *Rev. matériaux construction trav. publics* **1931**, 1–5, 45–9.—The properties of hydrated Ca aluminates and silicates are reviewed and compared with those of zeolites. The best explanation of the setting and hardening of the silicates seems to be the development of a network structure.
F. O. ANDEREGG

The influence of free lime in cement clinker on the solubility of lime and clay. KATSUZO KOYANAGI. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding 56–8(1931); cf. *C. A.* **25**, 1353.—Well-burned, low-lime clinker shows high soly. for clay and low for lime. An increase in lime greatly decreases the soly. of clay and increases that of lime. Low-lime cement when mixed with H_2O forms K aluminate crystals first, then $Ca(OH)_2$ and gels; with high lime the process is reversed. V. F. HARRINGTON

Suitability of argillaceous sands for cement mortar and concrete. WERKEN. *Zentr. Bauverwaltung* **50**, 671–3(1930).—Report on original tests, using sands with per-

centage of impurities up to 13.6. W. advises strongly against the use of impure sands. E. I. S.

Determining the proportions of mortars and concretes. LUDWIG SCHUSTER. *Tonind.-Ztg.* **55**, 224–5, 243–4(1931).—Examples are given of analyses of old mortars and concretes from which the approx. original compn. can be calcd. The analysis of the aggregate, if available, simplifies the calcn. F. O. ANDEREGG

Theory of composition and structure of concrete. A. M. GÜNZBERG. *Rev. matériaux construction trav. publics* 1930, 477–81; 1931, 21–5.—The space between the largest aggregate grains in concrete may range from 73 to 29%. To obtain the latter, very exact placing of each particle is required, which is hard to accomplish. Therefore, an intermediate range is selected with the ratios of sizes lying between 1:15:225 and 1:30:900; *e. g.*, cement 0.03 mm., sand 0.45 to 0.9 mm., gravel 7 to 27 mm. and plums 100 to 800 mm. This type of grading gives good packing. The water content is very important. G. suggests that the addn. of solutes, by lowering surface tensions, should reduce the voids in concrete. To get a porous concrete select those sizes and shapes which give poorest packing. F. O. ANDEREGG

The uniformity of concrete and its control on the job. FRITZ EMPERGER. *Tonind.-Ztg.* **55**, 382–3(1931).—Cubes and beams are made on the job and broken at 7 days. F. O. ANDEREGG

Calculation of the best composition of aggregate for concrete. H. RICHARZ. *Tonind.-Ztg.* **55**, 113–4(1931).—An example is given of a suitable blending of Rhine sand and Monier gravel that produced a grading closely approaching the ideal. F. O. A.

Testing protective coatings for concrete. P. MECKE. *Tonind.-Ztg.* **55**, 322(1931).—For accurate solvent detn. in bituminous prepns., place 5 g. in a small foil box contg. a small roll of gauze. After one hour at 100° distribute the bitumen evenly over the gauze and sides of the box and dry to const. wt. at 110°. To test the resistance to chem. effects cover a mortar slab with three coats after a cylinder has been cemented to the slab with neat cement. Place the soln. to be tested in the cylinder. F. O. ANDEREGG

Cracks in concrete. M. E. ROSSBACH. *Rev. matériaux construction trav. publics* 1931, 12–7.—Cracks developing in concrete result from a combination of shrinkage and insufficient tensile strength. Emphasis should be laid in securing a greater tensile elasticity in concrete, even at the expense of compressive strength, because concrete seldom fails in compression. F. O. ANDEREGG

Researches on the protection of concrete against corrosive waters. OTTO GRAF. *Zement* **19**, 936–41, 970–4, 995–8, 1041–3, 1066–8(1930).—The study of the corrosive action of water on concrete involves many factors beside the concn. of salt solns. Corrosive action increased with stirring of the solns. coarseness of cement used in the test pieces and poor gradation of cement particles, fineness of the sand used and quantity of mixing H_2O used, a deficiency being as objectional as an excess. The addn. of 3% clay to the specimens decreased their resistance to $MgCl_2$ solns. if they had not been air-cured. The compressive and tensile strengths were not decreased by clay addn. A curing period of 21 days in air after 6 days under H_2O made the mortar specimens (1:3) resistant to the attack of a 10% $MgCl_2$ soln. during 20 months' exposure. H. F. K.

The extraction of bitumen for testing from street paving material and the determination of sulfur in bitumen. FR. SEELIG. *Chem.-Ztg.* **55**, 145–6(1931).—Directions are given for the extn. of the bitumen (the method is claimed to be more accurate and reproducible) and for the complete combustion of the bitumen in the detn. of S. V. F. H.

Moldering of natural building stones and prevention of their quick decaying. O. LÁCZAY-FRITZ. *Magyar Mérnök Epitészegylet Közlönye Havi Füzetei* **7**, 1–21(1930).—The process of moldering is described. The ideal preventive agent should keep water out but should let the original moisture evaporate from the stone. The stones of the Hungarian Parliament Building were treated by Möller's method. This consists in spraying the stone surface with a paraffin liquid and repeating this process twice, each time after complete drying. The impregnation requires warmth, so is easiest in summer. If the stone is not warmed enough by the sun's rays, it must be heated artificially. The surface should be quite pure and dry. The cost of the treatment tried at the Cathedral at Pécs did not reach 40 (Hungarian) cents per sq. m. of surface. S. S. DE FINÁLY

Concrete coverings for pipe lines (HOUGH) **22.** Separation and size distribution of microscopic particles (ROLLER) **2.** Substitutes for sugars [in improving elasticity of cements and adhesives] (Ger. pat. 518,196) **18.** Compositions containing rubber and cement (Brit. pat. 339,002) **30.** S and bentonite mixture for use [as roofing] (U. S. pat. 1,795,364) **18.**

Cement. W. Reismann, R. H. Schloss and W. H. Evers. Brit. 338,664, Oct. 3, 1929. A cement for use as a binder in hydraulic mortar comprises a mixt. of finely ground slag 92 and burnt magnesite 8 parts together with 50 parts of a 25° Bé. Na silicate soln., suitably prepd., conjointly with admixt. with an aggregate such as sand.

Cement. Desider Vitéz. Austrian 120,861, Aug. 15, 1930. In the manuf. of cement from hydrated bauxite, *e. g.*, Hungarian bauxite, and CaO, the crude mixt. is only ground to such a degree that 3–6% is retained by a 900-mesh sieve, and the heating temp. does not exceed that necessary to frit the mixt., the duration of heating being less than 20 hrs.

Rotary kiln suitable for cement manufacture. Louis S. Petersen (to F. L. Smidth & Co.). U. S. 1,796,664, March 17. Structural features of a kiln provided with chains on its interior.

Rotating cement furnace. Pierre Bezard. Fr. 695,153, May 6, 1930. Means for feeding is given.

Concrete. Hans Fritz. Austrian 121,401, Sept. 15, 1930. A rapidly hardening concrete is prepd. by mixing an ordinary dry concrete mixt. with an aq. sludge of alumina cement. The amt. of alumina cement dets. the rapidity of the hardening. The concrete may be cast in molds made of or coated with Al or Zn.

Air-free concrete. John S. Morgan. Ger. 515,975, June 9, 1929. The cement is mixed with water in a centrifuge of high angular velocity, with or without the employment of a vacuum. Cf. *C. A.* **24**, 5129.

Steel reënforcements for concrete. E. Freyssinet and J. Seailles. Brit. 338,934, Nov. 19, 1928. High-tensile steel reënforcing members are used and are subjected to an initial tension substantially greater than the elastic limit of the steels "normally used" for reënforcing concrete. Brit. 338,864 relates to various articles of concrete thus prepd. and gives details of manuf.

Road materials. Rol, Lister et Cie. Fr. 37,369, Aug. 26, 1929. Addn. to 671,889 (*C. A.* **24**, 2266). Bitumen or asphalt is softened by crude or refined tar and mixed with mineral substances and an org. substance such as sawdust. The mixt. is applied cold.

Road-making compositions. Firma Georg Schicht and Ernest A. Kolbe. Austrian 121,552, Oct. 15, 1930. An addn. of asbestos, with or without an alk. earth sulfate and (or) kaolin, is made to the known compns. comprising stones and water-glass soln., with or without alk. earth or heavy metal oxides or hydroxides, hydraulic binders, etc. The binding is thus accelerated. Better binding is obtained also by using water-glass solns. that have been treated with CO_2.

Building construction units such as bricks. Howard C. Byland and Frank L. Ormesher (to Cemroc, Inc.). U. S. 1,796,559, March 17. Concrete, NH_4 stearate and $CaCl_2$ are poured into a mold, the concrete is subjected to a blow to reduce it appreciably in thickness, and the molded product is immediately withdrawn from the mold and allowed to dry in the air.

Weatherproofing building materials, particularly natural stones. Elektrochem. Werke München A.-G. Ger. 511,447, July 23, 1929. Fatty oils such as linseed oil are applied as aq. emulsions.

Disinfection of surfaces of natural and artificial stone. B. László. Hung. 101,351, Apr. 8, 1929. Stone surfaces are covered by a mixt. of 1 kg. flowers of S, 500 g. SnO_2, 1 kg. oxalic acid, 500 g. powd. glass, 500 g. 15% gelatin, 250 g. 15% gum arabic and 1 kg. turpentine. This film is covered by a mixt. of 1 kg. linseed oil, 0.1 kg. eucalyptus oil and 0.1 kg. benzoic acid.

Artificial stone. Paul Anft. Ger. 518,482, Aug. 14, 1929. Addn. to 390,433. According to Ger. 390,433, a quantity of wood meal, sawdust or the like is soaked in milk of lime to which KNO_3 has been added, while another quantity of wood meal, etc., is soaked in milk of cement to which K_2CO_3 has been added. The batches of wood meal, etc., are then dried and mixed while using cement as the binder. This method is now modified (1) by using $KMnO_4$ and alum in addn. to KNO_3, and (or) (2) by treating the wood meal, etc., in one batch with a mixed lime and cement milk to which all the reagents mentioned have been added.

Artificial stone and plastic masses. A. A. Bryushkov. Russ. appl. 68,506, April 17, 1930. Dried and ground sea weeds are added to clay dough together with water, or the weeds are first treated with a soda soln. and then mixed with clay.

Refractory stone. Firma Aug. Klönne. Ger. 515,535, Oct. 31, 1925. A light refractory stone is obtained by molding, drying and firing an intimate mixt. of kieselguhr, water and combustible material. The kieselguhr, which may or may not contain clay,

is well mixed with about an equal amt. of water before the combustible material is added. A small quantity of HCl may be added to the plastic mass before firing.

Artificial marble. BARTHÉLEMY J. BRUNEL. Fr. 37,177, Jan. 5, 1929. Addn. to 597,896. Ferrotitanium is used with $MgCl_2$ and $MgSiO_3$ for the production of artificial marble.

Making artificial marble from cements of various colors. KARL WALDERT. Austrian 121,563, Oct. 15, 1930. Manipulative details are described.

Using the residues of the artificial marble industry. ALEXANDER STAEGE. Ger. 515,519, Apr. 16, 1930. Addn. to 514,710 (*C. A.* 25, 2264). The MgO-contg. residue from the artificial stone and marble processes is extd. with dil. HCl and the remainder used as flux for portland cement.

Blocks and other shaped articles of alabaster and gypsum. F. J. G. GARNER. Brit. 338,465, Feb. 28, 1930. In order to give the articles the hardness and appearance of marble, they are dried by heating to 150–200°, impregnated with a soln. formed of water 1 gal., concd. Na silicate soln. 1 lb., $MgSO_4$ 1 oz. and fused $CaCl_2$ 1 oz., and then polished and rubbed with raw linseed oil.

Roofing material. GEORGE D. CRABBS U. S. 1,796,861, March 17. A flexible foundation material contg. a major proportion of mineral fiber such as asbestos is satd. with a relatively hard asphalt having a penetration not exceeding 11 at a temp. of 25°.

Roofing composition. GEORGE A. OSTERDAY (one-half to Edward Dome). U. S. 1,796,474, March 17. A mixt. is formed of pitch 25–40, asphalt 25–50, cork 25–50 and asbestos 5–10%

Dampproofing and waterproofing walls. JOSEPH ROSE. U. S. 1,796,269, March 10. The inner surfaces of walls are coated successively with a cementitious material such as a portland cement mixt. contg. emulsified asphalt, an overlying bonded coating of waterproofing material such as an asphalt paint and a finishing coating such as plaster, which is protected from dampness seeping through the wall by the underlying coatings.

Wires and wire netting for carrying plaster. C. SCHRÖDER. Brit. 338,755, Dec. 10, 1928. The wires are first coated with an adhesive such as glue, then treated with sand or volcanic ashes to form a facing, and then sprayed or washed with an aq. concrete mixt. or the like (leaving the meshes of the netting open).

Drying lumber, etc. HENRY W. COWAN. U. S. 1,796,141, March 10. The material is placed in a chamber the air in which is heated to a temp. capable of damaging the material on prolonged exposure, and hot moisture-laden air is periodically removed while dry air simultaneously admitted is to cause periodical reductions in temp. to below the damaging point through absorption of moisture from the material by the newly admitted dry air (which is heated to a suitable temp. in the chamber). App. is described.

Apparatus for partly impregnating timber. FRANZ KRAUSZ and LUDWIG TRAMER. Austrian 121,256, Sept. 15, 1930. Means is described for sealing the tank in which the trunk is partly immersed.

Impregnating wooden loom shuttles. I. G. FARBENIND. A.-G. Brit. 338,976, Aug. 30, 1929. The wood is impregnated with chlorinated org. compds. such as chlorinated naphthalenes or solid chlorinated biphenyl, suitably with conjoint use of a substance of lower m. p. such as paraffin or montan wax. Various details and examples are given.

Preserving wood. SOC. DE RECHERCHES ET DE PERFECTIONNEMENTS INDUSTRIELS. Brit. 339,247, April 8, 1929. The process of wood impregnation described in Brit. 310,805 (*C. A.* **24**, 707) is modified by the use of a soln. of As sulfide in an alkali sulfide such as Na sulfide as the first injected soln. which may also contain acetates and phenols, and this treatment may be followed by a second impregnation as described in Brit. 310,804 (*C. A.* **24**, 707). Various details and modifications of procedure are described.

Wood-preserving composition. BASILIUS R. V. MALENKOVIC. U. S. 1,795,658, March 10. A stable cryst. addn. product of 2,4-dinitro-1-chlorobenzene and α-naphthylamine is used, suitably with various other preservatives.

Developments in powdered fuel practice for marine service. E. W. GREEN. *Trans. Inst. Marine Eng.* **42**, 391–425(1930).—If powd. coal is used in Scotch marine boilers firebrick linings are not necessary to protect the walls but some sort of incandescent surface is needed. The fuel should be thrown from the burner with sufficient force to reach but not touch the boundaries. Fineness is the all-important factor in detg. the vol. of the flame. At least 97% of the product should pass a 100 I. M. M. screen and not more than 12% remain on the 200 screen. Ash ejectors remove the ash by way of the funnel. ANN NICHOLSON HIRD

Pulverized fuel for the small unit-shell type boiler, metallurgical and chemical processes. H. W. HOLLAND AND E. C. LOWNDES. *J. Inst. Fuel* **3**, 225–30(1930).—Brief discussion of pulverized-coal firing. It is used in cement, macadam and chemical plants. Comparative results of oil and coal firing are given. E. I. S.

Briquets for locomotives and their economic value. T. ISHIDA. *J. Fuel Soc. Japan* **10**, 233–46(1931); Section 2, 17–8(in English).—The Japanese Government Railways recently decided on the adoption of briquets as fuel for locomotives on certain trains on a heavy grade and began an investigation on the method of firing. The use of briquets of a certain kind causes a saving of 12.9% in the consumption of fuel and reduction of CO_2, CO and SO_2 in tunnels. A saving of 19.5% in the consumption of fuel was also reported for the special limited express train by using briquets instead of ordinary coal. F. I. NAKAMURA

Low-temperature distillation in Estonia. JOHN ROBERTS. *Colliery Eng.* **7**, 373–6 (1930).—A new type of low-temp. retort for carbonization of coal consists of a rectangular tunnel-oven large enough to take a car of shale or coal. From 50 to 70 tons can be handled per 24 hrs. ANN NICHOLSON HIRD

Notes on low-temperature carbonization. F. J. MATTHEWS. *Colliery Eng.* **8**, 65–7(1931).—The retort should be designed for high-oil production, high-calorific gas or best semi-coke as desired. ANN NICHOLSON HIRD

Aqueous liquors from low-temperature carbonization of coal. II. GILBERT T. MORGAN AND A. E. J. PETTET. *J. Soc. Chem. Ind.* **50**, 72–4T(1931); cf. *C. A.* **23**, 3326.—In addn. to previously isolated compds., *o*- and *m*-MeC_6H_4OH, 1-MeC_6H_3-3,4-$(OH)_2$, and 1-MeC_6H_3-2,3-$(OH)_2$, *m*- and *p*-$C_6H_4(OH)_2$ were identified by means of their phenylcarbamates. A liquor sample contained S (g./l.) in the form of the radicals of H_2S 1.02, H_2SO_3 0.24, $H_2S_2O_3$ 0.65, H_2SO_4 0.44, HCNS 0.2. A primary tar liquor from a carbonization at 450° (9 l. from 650 lb. coal) yielded 12 g. PhOH and 5.6 g. *o*-$C_6H_4(OH)_2$. *o*-MeC_6H_4OH, *m*- and *p*-$C_6H_4(OH)_2$ and AcOH were identified. C_5H_5N was completely absent. A comparison of low-temp. liquors from various coals showed that the yields of tar acid depended largely on the O content of the coals. Low-temp. carbonization gave much greater yields of tar acids than high-temp. carbonization of the same coals, but greater quantities of PhOH were formed at high temp. K. H. E

Coal as fuel about 1600. J. J. BLANKSMA. *Chem. Weekblad* **28**, 210–3(1931). G. G.

The chemical constitution of coal. WM. A. BONE. *J. Roy. Soc. Arts* **79**, 77–95 (1930).—Preliminary remarks deal with: coal as a problem in org. chemistry; the origin and formation of coals; exptl. methods used with coal; and the thermal decompn. of the coal substance. A wood-coal transformation series is outlined and the ultimate analyses of wood, lignin, peat, 3 brown coals, 3 lignites, a sub-bituminous, bituminous and an anthracite coal are tabulated. Another table gives the analyses of the gases evolved at successive temp. ranges in the thermal decompn. of dry Morwell brown coal. As mined this coal contains 55% water, all of which can be eliminated by drying at 110°. Data are given calcd. to cu. ft. per ton, also lb. of CO_2 plus CO, and of H_2O. The total amts. of O_2 evolved were, resp., at: 130–375°, 217 lb.; 375–500°, 215 lb.; 500–700°, 80 lb.; 700–850°, 144 lb.; total 656 lb. O_2 per ton dry coal. The H evolved varied from

nil in the first 2 ranges to 755 and 2165 cu. ft. per ton, resp., in the last 2 temp. ranges. With immature brown coals it is always possible to distinguish 3 successive and independent changes, resulting in successive expulsions from the coal substance of: (1) CO_2 and H_2O, as if by internal condensation; (2) methane, higher paraffins and olefins, as if by the elimination of aliphatic side chains from the coal complex, oils also appearing; and (3) H. With increasing maturity of coals these successive steps overlap and are not easily distinguishable on distg. well-matured bituminous coals. The "Soxhlet method" of benzene-pressure extn. of coals at 250, 500 and 700 lb. per sq. in. and results obtained thereby are outlined. The 4 different fractions obtained by this method from bituminous coals are described and their effects on coking properties discussed. Recent results from extn. expts. appear to furnish an explanation to the problem of the development of coking propensities during the maturing of coals. Extn. of certain immature brown coals yielded none of the usual Fractions III and IV but in their place a quantity of phenolic compds. (among which phenol, *p*-cresol and catechol were identified) and phenolic esters. Expts. on Canadian lignitic coals of somewhat greater maturity showed that brown lignites from Saskatchewan yielded phenolic compds. instead of fractions III and IV while with laminated black lignites from Alberta phenolic compds. were not obtained, but in their place a substance simulating fractions III and IV began to appear. These laminated black lignites appear to represent a transition stage in the development of fractions III and IV obtained from bituminous coal with coking properties. This conclusion is strengthened by recent exptl. proofs of the benzenoid character of fraction IV yielded by coking coals. The yields of fractions I, II, III and IV totaling 1.25-15.6% of the coal substance obtained from 9 different kinds of coal are tabulated. The last section of the paper is on the benzenoid character of the main coal substance (85% + of the coal) as shown by its oxidation with alk. permanganate (*C. A.* **24**, 5967). The C:H ratio of the original dry coals and of the dry residue after benzene-pressure extn. and the percentage of volatiles of the original dry ashless coal and of the dry ashless residues are given for 6 coals varying from immature brown coal to strongly coking bituminous coal. The C:H ratio was always higher in the dry residues and the percentage of volatiles always less than in the original coal. The wts. of acetic, oxalic and crude benzenoid acids obtained from 3 of the coals and the C:H in crude benzenoid acids are tabulated. A table on C balance of the oxidation shows the percentage of original C of the coal substances appearing as CO_2, acetic, oxalic, succinic and benzenoid acids. With the Morwell brown coal total C accounted for equaled 99.7%; with the Durham "Busty" coking coal 99.4%. The oxidation products from 3 of the coals have been completely investigated. From the Canadian Estevan brown lignite the products were: CO_2, and the acids: acetic, oxalic, succinic, phthalic, isophthalic, terephthalic, trimellitic, hemimellitic, trimesic, pyromellitic, mellophanic, benzenepentacarboxylic and mellitic. The same products except trimesic acid were obtained from Australian Morwell brown coal and with the exceptions of succinic, hemimellitic and trimesic acids from Durham Busty coking coal. The possible benzene-ring condensation compds. or condensed nuclei with aliphatic side chains present in the coal substance which give on oxidation the various acids isolated are discussed. The large new fields in coal chemistry opened up by this discovery and the possible great economic value of continued research along these lines are suggested. An extended discussion follows the article.

W. W. Hodge

Proximate analyses of coals from North China. S. D. Wilson. *J. Assoc. Chinese and Am. Eng.* **11**, No. 7, 9–22(1930); cf. *C. A.* **24**, 5460. E. I. S.

Unit coal studies on some Virginia coals. F. H. Fish and J. A. Addlestone. *Ind. Eng. Chem., Anal. Ed.* **3**, 155–8(1931).—The 3 formulas most commonly used for correcting the calorific value of coal to an ash-free basis are given and briefly discussed. To det. which formula could best be used in correcting ash to obtain unit B. t. u. for some Virginia coals, expts. were carried out on coal from 10 different seams and on 28 samples from the Merrimac seam. Coals from the 10 seams were ground to 20-mesh and float-and-sink sepns. made with CCl_4 + C_6H_6 of sp. gr. 1.35. Two tables give: (1) percentages of ash, S, observed B. t. u., calcd. B. t. u. by the 3 formulas and differences for untreated, float and sink coal from the 10 seams; and (2) percentages of ash, S, observed B. t. u. and calcd. B. t. u. for the 28 samples of Merrimac coal with deviations from the av. B. t. u. From these data the unit B. t. u. values calcd. by the Fieldner modification of the Parr formula were in best agreement. However, the differences were rather large and a second series of expts. was run to correct for CO_2. A description and a diagram of the app. used for detg. the CO_2 in coal are given. Two other tabulations summarize the new data obtained by modifying Parr's formula to correct for CO_2: the unit B. t. u. = (B. t. u. − 5000 S)/(1.00 − [1.08(ash + CO_2) + 22/40S]) and

Fieldner's formula unit B. t. u. = (B. t. u. − 4650S)/(1.00 − [1.08(ash + CO_2) + $^3/_4$S]). With these modified formulas the unit coal B. t. u.'s are in closer agreement. For the 10 coals examd. the av. of differences in unit B. t. u. between the untreated, float and sink portions of each coal was 82 B. t. u. by the Parr formula and 96 B. t. u. by the Fieldner formula. For the 28 samples from the same seam the av. deviation from the mean is ±75 B. t. u. by the Parr formula and ±86 B. t. u. by the Fieldner modification of this formula. These variations may be due to the inherent variations in the different layers of the coal seam, but if this factor is neglected the av. deviation is not much greater than the exptl. error in the B. t. u. detn. W. W. HODGE

Hungarian coal and coal-oil problems. I. VITÁLIS. *Bányás. Kohás. Lapok* **62**, 299–304, 323–32, 347–356(1929).—Expts. were carried out with highly bituminous brown coals of the Upper Oligocene of Bakony Mountain in Hungary. The quality of the extd. bitumen and of low-temp. tars corresponds with that of pyropissite found near Halle, Germany. S. S. DE FINÁLY

Preparation of pulverized lignite with pneumatic circulation drying. P. ROSIN AND E. RAMMLER. *Braunkohle* 29, 557–63(1930).—Circulation drying is a pneumatic process according to which the transport and drying of wet products in suspension are effected by hot gases which circulate at high speed through a pipe system. Details of a circulating drier are given. E. I. S.

Calculations and investigations of lignite-briquet cooling. H. SCHUSTER. *Braunkohle* **28**, 305–18(1929).—It is technically possible to cool briquets to about 2 to 3% of the surrounding temp., and loading at this temp. without the possibility of further cooling in car is considered safe in respect to quality of briquet and self-ignition hazard. E. I. S.

By-product ammonia. H. HOLLINGS AND E. W. SMITH. *Inst. Gas Eng. Communication* No. **19**, 25–30(1930).—A discussion is given of possible ways and means for increasing the net value of NH_3 at the gas works, which in many cases under existing conditions does not pay the cost of its removal from the gas. Production in Great Britain is equiv. to 150,000 tons of $(NH_4)_2SO_4$ annually. At the present time the Comm. cannot indicate any new research in this field with any reasonable prospect of economic advantage. H. L. OLIN

Preparation of ammonium sulfate in the form of coarse thick plates. W. GLUUD, W. KLEMPT AND H. RITTER. *Ber. ges. Kohlentechnik* **3**, 371–84(1931).—The effects of various conditions upon the cryst. form of coal-tar $(NH_4)_2SO_4$ were studied. Temp. and rate of crystn. and the quantity of such impurities as pyridine, tar acids, phenol and As appeared to have no effect upon the form of the crystals, but Fe did appear to be the detg. factor. To det. the effect of Fe salts, the Fe present in the crude liquors was pptd. out with H_2S and then definite quantities of Fe salts were added. Fe^{III} ion had an injurious effect upon the cryst. form, only a fine crystal brew being obtained in its presence. Cr and Al have the same effect, but the lower-valence forms of Fe, Mn and Co on the other hand have very favorable effects. The quantities of Fe, Mn and Co used were 2.4 g. of sulfate per l. If it is desired to get the same cryst. form of sulfate as is obtained from synthetic NH_3, it is necessary to remove the Fe. This is accomplished by oxidation to Fe^{III} and pptn. as hydroxide by making alk. with NH_3. H. STOERTZ

Naphthalene removal with tetralin. P. DEUTSCH. *Gas u. Wasserfach* **74**, 245–7 (1931).—A satisfactory naphthalene solvent to be introduced into gas mains must be (1) a good solvent for naphthalene, (2) of low vapor pressure to avoid too great losses, (3) of higher vapor pressure than naphthalene in order to be present in sufficient amts. to dissolve the condensed naphthalene. The vapor pressure of naphthalene and a series of possible naphthalene solvents, as well as the soly. of naphthalene in these solvents, are given for 0° and 20°. Tetralin satisfies the above conditions best. A given gas contained 13 g. naphthalene per 100 cu. m. On cooling from 20° to 0° 8.5 g. of naphthalene will be deposited per 100 cu. m. of gas. 62.5 g. of tetralin is required to dissolve this amt. of naphthalene at 0° (satd. soln.) and 60 g. to sat. the gas at 0° or a total of 122.5 g. of tetralin per 100 cu. m. of gas. The vapor pressure of tetralin is such that gas at 20° can carry 200 g. per 100 cu. m. Xylene can dissolve 20.8 g. of naphthalene per 100 g. at 0° so only 32.3 g. of xylene is required to dissolve the naphthalene. However, the gas requires an addnl. amt. of 1690 g. xylene to sat. itself at 0°, or a total of 1722 g. must be added to the gas to insure sufficient xylene condensate to dissolve the naphthalene when the gas is cooled to 0°, over 10 times as much as with tetralin. At Bremerhaven tetralin costs 55.25 marks per 100 kg. The total cost of adding tetralin for the first year was 2.9 pfg. per 100 cu. m. The typical app. for vaporizing tetralin is described and illustrated. Experiences in other cities are given. D. regards tetralin as the single satisfactory means for combating naphthalene and removing tarry deposits from mains. R. W. RYAN

Esthonian combustible shales. OTAKAR VONDRÁČEK. *Chem. Listy* **24**, 471–3 (1930).—Combustible shales are located between the cities Tapa and Narva and cover 2470 sq. km. The shales contain 70% org. matter which came from a rich sea fauna; the shale burns with a luminous flame and emanates an oily odor. The shales are used in the industry and in firing locomotives; a great deal of fine ash forms which penetrates everywhere. The ash nuisance is obviated by using an oil prepd. by the destructive distn. of shale. FRANK MARESH

The Italian gas industry. R. DECKERT. *Gas u. Wasserfach* **74**, 203–4(1931).—Facts and figures are given for the Italian gas industry. R. W. RYAN

Determination of the heating value of gases by explosion. 'HANS LÖFFLER. *Arch. Wärmewirt.* 11, 403–4(1930); cf. *C. A.* **25**, 207.—An app. is described and illustrated in which the gas is mixed with a definite vol. of air and exploded, the heating value being detd. by the rise in temp. of a Hg thermometer placed in the center of the pipet, which is built like a Dewar flask. The calibration appears to be empirical. E. W. T.

The 25th report of the Joint Research Committee of the Institution and Leeds University. Examination of the products of combustion from typical gas appliances. V. THOMAS HARDIE, *et al. Inst. Gas Eng. Communication*, No. 16, 50 pp.(1930).—Tests on properly adjusted surface combustion water heaters showed CO in waste gas less than 0.01%. Similar tests with inverted incandescent mantle burners indicated a higher rate of CO production than with the Bunsen flame especially at gas rates lower than normal. The rapid increase of CO when the burner was turned low points to the advantage of using a smaller unit at full capacity when little light is required. H. L. OLIN

Some further experiments on the combustion of inflammable gases by electric sparks. J. D. MORGAN. *Phil. Mag.* [7], **11**, 158–63(1931); cf. *Phil. Mag.* **43**, 359 (1922); *C. A.* **17**, 2505.—Weak mixtures of coal gas with air at atmospheric temp. and pressure were subjected to a stream of high-tension sparks, maintained without burning in the gas. Combustion in the mixture is proportional to the heat energy of the spark discharge when the gap width is constant; and proportional to the gap width when the heat energy is constant. The results are consistent with the previous theory. ARTHUR FLEISCHER

The 27th report of the Joint Research Committee of the Institute and Leeds University. First report on the back-run process for the manufacture of carbureted water gas. THOMAS HARDIE, *et al. Inst. Gas Eng. Communication* No. **18**, 47 pp.(1930).—This report covers an elaborate test made to det. the efficiency of production of carbureted water gas in a modern, automatically operated plant, equipped with generator boiler and self-clinkering grate and designed to use the back-run principle of heat regeneration. Results are given in condensed form: time of test, 96 hrs.; coke to generator, 151.3 tons; thermal value of coke, 12,910 B. t. u.; oil to carburetor, 20,163 gallons; thermal value, 19,640 B. t. u. per lb.; total steam (30 lb. pressure) to generator, 313,000 lb.; av. percentage of steam decompd., 60.8; total carbureted water gas made (purified) 9,534,000 cu. ft.; thermal value of gas, 503 B. t. u.; efficiency of production of carbureted water gas, 69.3%; efficiency of production of blue water gas, (*a*) accounting for extra steam to generator and steam to auxiliary plant, 49.3%, (*b*) without accounting for such steam, 55%. H. L. OLIN

The 26th report of the Joint Research Committee of the Institution and Leeds University. Second report on the use of creosote in the manufacture of carbureted water gas. THOMAS HARDIE, *et al. Inst. Gas Eng. Communication* No. **17**, 7 pp.(1930).—Gas oil, light and heavy creosote, and mixts. of gas oil and creosote were cracked over a temp range of 700–900° in atms. of H_2, H_2 and CO, and H_2, CO and steam. The tabulated data indicate the highly unsatisfactory results obtained:

Kind of oil	Therms per gal. of oil	Percent tar	Percent naphthalene
gas oil	1.211	30.1	3.0
light creosote	0.489	67.7	16.0
heavy "	0.167	80.3	18.3
mixt. of 80% gas oil–20% light creosote	1.054	40.1	6.3

H. L. OLIN

V. D. I. rules for gas-flow measurement with standard nozzles and orifices. K. BUNTE AND L. ZIPPERER. *Gas u. Wasserfach* **74**, 250–4(1931).—Flow formulas are given as well as drawings of standard nozzles and orifices, and practical applications. R. W. RYAN

Testing gas-distribution systems with ethyl mercaptan. A. THAU. *Gas u. Wasserfach* **74**, 247–50(1931).—A discussion is given of the expts. carried out in 2 American cities with Et mercaptan to detect leaks in distribution system, and possible application to German conditions. R. W. RYAN

Simple flue-gas diagram for excess air. L. ZIPPERER. *Gas u. Wasserfach* 74, 199–200(1931).—A simple diagram is given for facilitating the estn. of flue-gas concns for a given gas with various amts. of excess air. R. W. RYAN

The dew point of the flue gases of solid fuels. W. GRAULICH. *Feuerungstech.* **19**, 26–8(1931).—G. asserts that the H content on a wet basis is nearly the same for all solid fuels. This assumption enables him to draw a simple diagram relating dew point of flue gases to the water content of the fuel and to the excess air. ERNEST W. THIELE

Coal gas for heating retorts in small gas works. ERICH DUBOIS. *Gas u. Wasserfach* **74**, 269–74(1931).—The alternative use of coal gas may permit better balances between gas send-out and coke demand. An economic study is necessary to det. the desirability of using coal gas for heating retorts in each case. R. W. RYAN

Use of sewage gas as city gas. W. H. FULWEILER. *Sewage Works J.* **2**, 424–34 (1930).—The collection of gas from digestion or Imhoff tanks is not justified in the U. S. as a substitute for city gas because (1) it has a relatively high sp. gr. (0.77) which would necessitate greater expenditure of power for pumping and decrease the capacity of the distribution system; (2) it has a very low H content which gives rise to undesirable flame characteristics; (3) the max. production which could be expected is only 1% of that required for city gas and this would be produced in summer when it is least required; and (4) the enriching quality which sewage gas possesses because of its high B. t. u. value (650 to 800) is obtained at considerably lower cost by the use of bunker oil. E. HURWITZ

Valves for blast-furnace and producer gas. A. JOHANSSON. *Jernkontorets Ann.* **114**, No. 7, 368–72(1930).—Detailed description of 600-mm., 300-mm. and 180-mm. valves used in Swedish iron works designed to prevent soot accumulation on the valve seat. E. I. S.

The gas producer. I. Continuous producer. II. Operation and items related to operation. III. Conduction of gas-producer fuel tests. JOHN W. ROMIG. *Am. Gas J.* **133**, No. 2, 47–8, No. 3, 44–5, No 4, 68, 73–4, No. 6, 45–6, 59(1930); **134**, No. 1, 54–5(1931). E. H.

The disposal of liquor effluents from gasworks. A. C. MONKHOUSE AND W. ETHERIDGE. *Inst. Gas. Eng. Communication*, No. 21, 12–30(1930), cf. C. A. 23, 5562.—The report is presented under 3 heads: (*a*) methods of reducing the higher tar acid content of NH_3 liquor, (*b*) the evapn. of effluent liquor on producer bars and (*c*) the biological purification of effluent liquors. The principal studies under (*a*) were directed on the effects of keeping the heavy tars out of contact with the main effluent liquors and thus keeping tar acids out of the latter. Highly promising results with the Cottrell electrostatic tar sepn. and with the Cyclone tar extractor are cited. Under (*b*) the method of evapg. "devil" liquor by spraying it on the grates of producers operated in connection with vertical gas retorts was found to be successful since no fumes or other nuisance was noted. It was estd. that the total "devil" liquor output and 27% of the spent liquor from the NH_3 still could be disposed of in this way. (*c*) Spent still liquor from the Coventry Gasworks amounting to 7,152,000 gallons in 1930 with an O_2 absorption value 9560 p. p. m. is being reduced to 985 p. p. m. by treatment on bacterial beds. The latter, which consist of graded granite about 5 feet deep, are activated during rest periods with sewage. H. L. OLIN

Catalytic desulfuration and hydrogenation of a primary tar fraction. J. M. PERTIERRA. *Anales soc. espaü. fis. quim.* **28**, 1435–50(1930).—The S content, existing as H_2S, mercaptans, thioethers, and thiophene derivs. of a 180–300° fraction of primary tar, was detd., then the tar fraction desulfurized by passing the vapors by means of a current of dry H_2 over oxides previously reduced and heated to 300–350°. Two passages over the catalyst reduced the S content 60%. A second catalyst following the first reduced the base content 64.2% and the tar phenols 13.3%. In hydrogenating com. primary tar from which fractions boiling below 180° had been removed previously, by the Bergius process with Fe and Mo oxides as catalysts, there is obtained a benzine, b. 50–185°, with a content of phenols and bases reduced 73.9% and 59.3%, resp., and wholly sol. in Et_2O, which proves the transformation of the 2.6% "ulmins" of primary tar. E. M. SYMMES

The coking industry and its development in relation to the manufacture of iron and steel. JAMES K. DICKIE. *J. West. Scotland Iron & Steel Inst.* **38**, Pt 4, 45–55(1931). E. H.

Influence of water in the by-product coke oven. G. E. FOXWELL, *Colliery Eng.* **7**, 307–9, 338–40(1930).—The occurrence of hygroscopic moisture seems to depend on the presence of minute pores in the material. Coke made from coal contg. much hygroscopic moisture is very reactive. Water vapor affects the yield of NH_3. Financial effects are discussed. ANN NICHOLSON HIRD

Gas coke as a raw material for household briquets. R. KADA. *J. Fuel Soc. Japan* **10**, 219–32(1931); Section 2, 15–7(in English).—K. manufd. briquets by mixing

semi-coke with gas coke in various proportions and studied their properties. The equiv. mixt. of semi-coke and gas-coke produces most suitable briquets which resemble anthracite briquets in their combustibility. K. also suggests the production of coke suitable for household briquets by adjusting the temp. of carbonization. F. I. NAKAMURA

Formation of CS_2 from H_2S and coke (DRAKELEY, BAKER) **18**. A new physicochemical explanation of the formation of humus, peat and coal (ZOLCINSKI) **8**. Beneficial action of brown coal upon the development of cultivated plants (KISSEL) **15**. Oven for dry distillation of brown coal (U. S. pat. 1,796,264) **22**. Phenols (Brit. pat. 338,638) **10**. Apparatus for separating peat fiber from liquids (Brit. pat. 338,547) **23**. Combined reduction of ores and hydrogenation of carbonaceous materials (Brit. pat. 339,276) **9**. Destructive hydrogenation (Brit. pats. 338,544, 338,576 and 339,317) **22**. Purifying bitumen, etc. (Brit. pat. 339,470) **22**. Distilling or drying carbonaceous materials (Brit. pat. 338,939) **13**.

RE, UMBERTO, AND VARETON, E.: **Carburanti e carburazione.** Milan: Ulrico Hoepli. 516 pp. L. 50. Reviewed in *Ind. Eng. Chem.* **23**, 597(1931).

Method and plant for drying fuels with circulated superheated steam. RUDOLF STEINER and VIKTOR SKUTL. Austrian 121,405, Dec. 15, 1929.

Low-boiling liquid fuels from coals, tars, oils or bituminous materials. A. ROMWALTER. Hung. 100,880, Dec. 5, 1929. The raw materials are powdered or vaporized and treated at 350–550° with a mixt. of CO and steam at a partial pressure lower than 1 atm. The low-boiling liquid fuels formed are led away in vaporized form.

Motor fuel. I. G. FARBENIND A.-G. Fr. 37,306, Aug. 5, 1929. Addn. to 643,785 (*C. A.* **23**, 1739). In the process of the prior patent the extn. is carried out in steps under conditions which become more and more severe and the residue is afterward submitted to hydrogenation under pressure.

Fuel briquets. GUSTAV KOMAREK (one-half to Monarch-Greaves & Co., and one-fourth each to George MacPhail and Charles Coryell). U. S. 1,796,465, March 17. Petroleum coke is used with a coke product from the destructive distn. of coal.

Charcoal for iron metallurgy. E. GABROVITZ. Hung. 101,960, Jan. 7, 1930. Briquets are formed from charcoal dust and lime-contg. water. *E. g.*, 22.5 parts CaO is added to 100 parts H_2O, then 80 parts of this solution is mixed with 100 parts of powd. waste charcoal and charcoal dust and the forms are pressed under 2–3 atm.

Distilling fine bituminous material. KOHLENVEREDLUNG A.-G. Ger. 515,911, Mar. 18, 1924. The finely powd. material is treated with a blast of hot gas so that the distn. begins at above 800°.

Apparatus for continuously distilling carbonaceous materials and cracking or hydrogenating the vapors. "INTERCARBO" SOC. ANON. POUR LA CARBONISATION ET LA TRIATEMENT CATALYTIQUE DES COMBUSTIBLES. Ger. 518,403, Mar. 26, 1927. See Brit. 277,404 and 278,041 (*C. A.* **22**, 2655).

Destructive hydrogenation. H. P. DEAN and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 339,040, Oct. 4, 1929. In a described app. for the destructive hydrogenation of liquid carbonaceous material, the H is passed into the reaction chamber through an indirect heat exchanger surrounded by the material and which may be made of or coated with catalytic material.

Destructive hydrogenation. GUTEHOFFNUNGSHÜTTE OBERHAUSEN A.-G. Brit. 339,048, Oct. 8, 1928. Fatty oils such as soy-bean oil are converted into products suitable for operation of internal-combustion engines by heating to above their b. ps. in the presence of H at a pressure below 45 atm. (suitably by use of illuminating gas) and a catalyst prepd. by pouring dil. Na_2CO_3 over Fe oxide and drying and reducing the mixt.) Use of catalysts contg. Zn and Cu is also mentioned. If desired, the process may be carried out in 2 sep. stages, vapors being formed in the first stage and catalytically hydrogenated in the second stage.

Apparatus for destructive hydrogenation. W. R. TATE, H. P. STEPHENSON, J. F. LEHMANN and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 339,479, Nov. 29, 1929. Various details of app. are described, particularly relating to control of the liquid level in a reaction vessel or catch pot.

Apparatus for low-temperature distillation of solid carbonaceous materials such as coal or oil shale. OSWALD HELLER (to Bamag-Meguin A.-G.). U. S. 1,796,100, March 10. Various structural details are described of an app. comprising rotating drums and adapted for heating the material undergoing distn. by use of preheated heat-accumulating elements which may have a net-like cross section.

Hydrogenating coal, etc. I. G. FARBENIND. A.-G. Fr. 37,394, Sept. 6, 1929. Addn. to 666,683 (*C. A.* **24**, 1204). Other means than that in Fr. 666,683 is used to keep the catalyst dispersed in the liquid contained in the reaction chamber, *e. g.*, the catalysts may be used in the colloidal state so that they remain easily in suspension, or the difference in d. between the substances to be treated and that of the catalyst is reduced so that the catalyst remains easily suspended. Examples are given.

Preparing peat for briqueting. MADRUCK, GES. FÜR MASCHINELLE DRUCKENTWÄSSERUNG M. B. H. Brit. 338,950, Aug. 23, 1929. Raw peat is mixed with peat dust (preferably in such quantity that the wt. of dry material in the dust exceeds that in the raw peat), and the mixt. is highly compressed (as by a hydraulic press) to ext. water. Numerous details of app. and operation are described.

Lignite distillation. H. DEBAUCHE. Brit. 339,129, Dec. 17, 1929. Destructive distn. is effected in an app. such as described in Brit. 270,921 (*C. A.* **22**, 1673), first at relatively low temp. (300–500°) and then at higher temp. (suitably 800°), for removal of heavy hydrocarbons and production of a clean and brilliant coke suitable for making briquets (various details of manuf. of which also are given). App. is described.

Plate drier for lignite. "EINTRACHT" BRAUNKOHLENWERKE UND BRIKETTFABRIKEN and MAX MAYER. Ger. 515,520, Dec. 11, 1929. Addn. to 514,711 (*C. A.* **25**, 2273). Constructional details.

Phenols from industrial liquors. FRITZ ULRICH (to Zeche Mathias Stinnes). U. S. 1,795,382, March 10. Phenol-bearing liquors such as ammoniacal liquors are treated with tar bases such as pyridine or quinoline in order to improve the recovery of phenols.

Preparing highly concentrated ammonia gas from ammoniacal liquor. L. F. FOKIN and E. E. LIDER. Russ. appl. 18,221, May 4, 1927, addn. to pat. No. 3856. Concd. ammoniacal liquor is dild. with hot waste water from the distn. column. The hot, dil. mixt. is passed through the dissociator for the removal of CO_2 and H_2S in gaseous state. The partly purified water is then freed from NH_3, H_2S and CO_2 in the distn. column.

Purifying benzenes. I. G FARBENIND. A.-G. Fr. 37,363, Aug. 23, 1929. Addn. to 621,505. The purification of benzene or the intermediate product by a treatment with H under pressure and at a high temp. in the presence of catalysts not attacked by S is carried out in a single operation with the hydrogenation of substances such as coal, hydrocarbons or their derivs.

Apparatus for desuperheating steam. SUPERHEATER CO., LTD., and COMPAGNIE DES SURCHAUFFEURS. Brit. 339,575, March 19, 1930. Structural features.

Gas production. A. S. RAMAGE. Brit. 338,905, Aug. 24, 1929. Olefins, terpenes or acetylenic hydrocarbons, substantially free from paraffinic hydrocarbons, are passed, at a temp. of about 420–700°, over iron, with 20–30% or more of steam, producing mainly H, CO and CH_4, and leaving the iron as metal. Various details of app. and procedure are described. Cf. *C. A.* **24**, 2866.

Fuel gas. HERMANN HEBEL. Austrian 121,094, May 15, 1930. In the manuf. of fuel gas by degasifying coal and converting the residual coke into water gas, the degasification is effected by leading a part of the water gas through the degasifying retort and another part around the retort, the latter part being afterward reheated and returned to the water-gas generator with superheated steam. The calorific value of the gas may be regulated by controlling the amt. of water gas admitted to the degasifying retort, complete degasification being in any case ensured by regulating the temp. of the water gas so admitted, and also the temp. and the amt. of water gas led around the retort. Cf. *C. A.* **24**, 228.

Fuel gas. ANTON KRATKY. Austrian 121,099, Aug. 15, 1930. Gas for heating or for driving internal-combustion engines is prepd. by the action of steam at 500–1000° on atomized or gaseous or vaporized hydrocarbons in a chamber heated electrically to approx. the temp. of the steam. Ale vapor may be mixed with the steam. App. is described.

Fuel gas from bituminous materials. ARTHUR H. LYMM Ger. 515,982, Feb. 22, 1927. Details of retorts and method of distg. are given.

Coal gas. MARIA T. STRACHE. Austrian 121,540 and 121,542, Oct. 15, 1930. Addns. to 118,062 (*C. A.* **24**, 4921). In the method of Austrian 118,062, uniform distribution of the fresh fuel and tar is effected by feeding the fuel to the generator through the tar which may act as a seal for the generator. App. is described (121,540). Addnl. tar may be added with the fresh fuel, besides the tar produced in the gasification. Low-temp. tar, generator tar, wood tar, or lignite tar may be so added. Mineral oils or their distn. products or residues may be added also (121,542).

Desulfurizing coal-distillation gases, etc. ISTVÁN HUNYADY and KARL KOLLER. Ger. 518,431, May 11, 1928. The gases are freed from tar, NH_3 and CN compds., and

then treated with an aq. suspension of $Mn(OH)_2$. The sludge of MnS and S so obtained is withdrawn and treated with SO_2, to produce a suspension of S in an aq. soln. of MnS_2O_4. The soln. is sepd. and treated in turn or simultaneously with the gases to be purified and with SO_2, whereby MnS_2O_4 is converted into MnS_3O_6, which is stable to H_2S. The soln. of MnS_3O_6 is then boiled, yielding $MnSO_4$, S and SO_2. The $MnSO_4$ is treated with NH_3 and O to regenerate $Mn(OH)_2$.

Oil gas. FRANK J. NOLAN. U. S. 1,796,299, March 17. A mixt. of vaporous hydrocarbon material and steam is introduced to a zone contg. a plurality of individually spaced metallic catalysts such as an alloy of Al 50, Ni 15, Cu 10, Ti 10, Ag 2, Mg 10 and Bi 3%, each spanning the zone and heated to above 540° and the mixt. is passed over the catalysts without further addn. of steam and the gas produced is withdrawn for collection. App. is described.

Oil gas. A. S. RAMAGE. Brit. 338,904, Aug. 24, 1929. Materials such as heavy mineral oils are passed, with 1–2% of steam, over ferric oxide at a temp. of about 420–540° and the (largely olefinic) gases thus formed are passed, with 10–40% of steam, over finely divided iron at a higher temp. (suitably about 600–800°), producing a gas contg. H, CO, CH_4, C_2H_4 and some aromatic hydrocarbons. Motor fuel is sepd. from the gas, and various details of app. and procedure are described.

Water gas. A. F. KUNBERGER (to Humphreys & Glasgow, Ltd.). Brit. 338,804, March 2, 1929. H produced by passing steam over hot iron is superheated and carbureted and then passed with excess steam through the upper part of the fuel bed (the whole of which is used simultaneously in generating water gas by "up-running") and the mixed gas is taken off above the fuel bed. Various details of app. and operation are given.

Water-gas producer. MOTOR FUEL PROPRIETARY, LTD., and W. JOHNSON Brit. 338,877, Aug. 26, 1929. Various details are described of an app. having an inner generator located within an annular generator, charges in each generator being independently gasified.

Water-gas producer for the continuous distillation of powdered fuel. JULIUS PINTSCH A.-G. Fr. 37,192, July 4, 1929. Addn to 658,586 (*C. A.* **23**, 5307).

Apparatus for making water gas from pulverulent fuel. HARALD NIELSEN and BRYAN LAING. Ger. 518,427, May 31, 1927. See Brit. 299,485 (*C. A.* **23**, 3333).

Gas producer. S. I. R. I., SOC. ITALIANA RICERCHE INDUSTRIALI. Brit. 338,911, Aug. 27, 1929. See Fr. 680,849 (*C. A.* **24**, 3932).

Gas producer (suitable for generating gas from solid fuels on automobiles). WM W. ODELL and EARL N. PERCY. U. S. 1,795,670, March 10. Structural features.

Combined gas-producer furnace suitable for heating metals. R. A. HADFIELD and R. J. SARJANT. Brit. 338,893, June 26, 1929.

Gas-generating plant. ADOLF WEIGEL. Ger. 515,983, May 10, 1925. Details of a surface cooler for the gases produced are given.

Apparatus for producing fixed combustible gas from fluid fuels such as oil. ORRELL O. THWING (to General Oil Gas Corp.). U. S. 1,796,733, March 17. Numerous structural details are described.

Enriching combustible gases. HERMAN A. BRASSERT and CHARLES W. ANDREWS (to H. A. Brassert & Co.). U. S. 1,795,829, March 10. A gas to be enriched, together with a regulated proportion of air, is passed through a mass of partly consumed coke at high temp., then through a mass of coke at still higher temp. which will effect formation of CO from CO_2, and a controlled proportion of preheated air is introduced laterally into the last-mentioned coke mass, and the gas is then passed through a mass of coal at a lower temp. to effect enrichment. App. is described.

Washing flue gases, etc. P. J. ROBINSON. Brit. 338,492, May 18, 1929. Gases such as flue gases are passed through a centrifugal dust separator, adjusted to leave a regulable small proportion of fine dust in the gases, and are then subjected to steam or fine water sprays to wet the remaining fine dust particles and effect oxidation of SO_2 to SO_3, after which the gases are caused to impinge upon baffle plates and are washed with a heavy shower of water to remove the dust and acid. Various details of the app. (which may be formed of Ni-Cr steel resistant to corrosion) and of operation are described.

Regenerative heat-storing device, especially for preheating fuel gas. AKTIEBOLAGET LJUNGSTRÖMS ÅNGTURBIN. Ger. 515,870, Nov. 15, 1927.

Refining tars, oils, etc. I. G. FARBENIND. A.-G. (Carl Krauch and Mathias Pier, inventors). Ger. 515,523, Aug. 15, 1925. The tars, oils, distn. products, residues, etc., are treated with H or H-evolving materials at high temps. and pressures, optionally, in the presence of catalyzers. The material to be refined by this process is intimately mixed with up to 30% peat or lignite or a mixt. of both. In an example, lignite-gener

ator tar is mixed with 20% crude lignite and heated in a Mn-bronze-lined high-pressure reaction chamber to 450°, and subjected to the action of H at 200 atm. A 20–35% yield of benzine results. Further examples are given. Cf. *C. A.* **24**, 4378.

Distillation of tar. ALEXANDER A. MACCUBBIN and JOSEPH ZAVERTNIK (to The Barrett Co.). Can. 309,218, Mar. 10, 1931. A method and app. are specified in which tar is distd. at atm. pressure to produce distillate oils and a pitch residue. The pitch residue is withdrawn during distn. at approx. the temp. of the first distn. and immediately subjected to a high vacuum to effect further distn. of high-boiling oils by the self-contained heat of the pitch. Cf. *C. A.* **24**, 2585.

Removing acid constituents from low-temperature tar or its fractions. CURT BUNGE and FORSCHUNGSINSTITUT FÜR BERGWERKS- UND SPRENGSTOFFCHEMIE SOWIE VERWANDTE GEBIETE. Ger. 518,210, Sept. 13, 1925. An aq. emulsion of the tar or tar fraction is treated with alkali soln. The emulsion may be prepd. with the aid of soap, and the treatment with alkali soln may be effected in a no. of stages.

Chamber oven for the production of gas and coke. C. OTTO & CO. G. M. B. H. Ger. 515,978, Oct. 20, 1926. Details of heating the distn. gas to produce gas of better illuminating quality are given. Cf. *C. A.* **24**, 4379, 5139.

Coke oven. RUDOLF WILHELM (to Arnold Beckers). U. S. 1,795,324, March 10.

Coke oven. KOKSOFENBAU UND GASVERWERTUNG A.-G. Ger. 512,334, Nov. 22, 1927. The heating channels are lined with steel or other heat-resistant metal.

Regenerative coke ovens. COLLIN & CO. Fr. 37,387, Sept. 2, 1929. Addn. to 576,379.

Regenerative compound coke oven with twin outlets. C. OTTO & CO. G. M. B. H. Ger. 515,849, Aug. 18, 1929. Addn. to 503,895 (*C. A.* **24**, 5987)

Coke-oven battery with horizontal chambers. THE KOPPERS CO. Ger. 518,312, Dec. 15, 1928. See Brit. 302,365 (*C. A.* **23**, 4331).

Heating wall for coke-oven chambers. KOKSOFENBAU UND GASVERWERTUNG A.-G. Ger. 518,385, April 29, 1926.

Coke oven (door construction, etc.). R. & J. DEMPSTER, LTD., and C. E. HOLT Brit. 339,557, Feb. 19, 1930.

Coke-oven door. HEINRICH SCHWARZ. U. S. 1,795,515, March 10.

Coke-oven door. E. WOLFF. Brit. 338,450, Oct. 9, 1929.

Coke-oven cover. ARTHUR KILLING and WILHELM ELBERT. Ger. 515,538, Aug. 19, 1928

Method and plant for drying coke. WESTFÄLISCHE MASCHINENBAU-GES. M. B. H. Ger. 518,313, June 17, 1930.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

Petroleum mine in the old Groznui District. L. LUTOVINOV. *Azerbaïdzhanskoe Neftyanoe Khozyaĭstvo* **1931**, No. 1, 57–63.—A complete description is given of the proposed method of mining oil similar to that adopted in Pechelbronn (France).
V. KALICHEVSKY

Determination of the toluene content of a Mid-Continent petroleum. JOHANNES H. BRUUN, R. T. LESLIE AND SYLVESTER T. SCHICKTANZ. *Bur. Standards J. Research* **6**, 363–7(1931).—Com. petroleum fractions from an Okla. crude oil were fractionated into 1° cuts and tested for toluene by nitrating to 2,4-dinitrotoluene by means of a nitrating method which was found not to attack the other constituents of the fractions. Toluene was found in all the cuts boiling between 90° and 112°. The max. concn. (32.2%) was found in the fraction boiling between 107° and 108°. Total toluene present amounted to 1/3 of 1%, based on the crude petroleum.
D. F. BROWN

Separation of normal octane from petroleum by distillation and crystallization. R. T. LESLIE AND SYLVESTER T. SCHICKTANZ. *Bur. Standards J. Research* **6**, 377–86(1931).—A fraction b. 100–130° from an Okla. crude oil was subjected to an interlocking process of distn. and crystn. to sep. octane. The method and app. are described in detail. The b. p., f. p., refractive index and mol. wt of the product are given and compared with the properties of a carefully purified sample of synthetic octane. It is estd. that not less than 1% of octane was present in the oil investigated.
D. F. BROWN

The acids of Baku petroleum. A. E. CHICHIBABIN. *Compt. rend. acad. sci. U. R.*

S. S. **1930A**, 382–4.—A summary is given of work done on petroleum and naphthenic acids. The sepn. of the acids from the lower fractions as amides showed that fatty acids with 7 C atoms were present. Bromination and sepn. of HCOOH from the hydroxy-acids prepd. from the bromocarboxylic acids indicated that the carboxyl group is bound to primary radicals as well as to secondary and tertiary radicals. By sepg. the acids into cyclic and fatty acids by means of their Cd salts, it was found that the petroleum acids b. 215–18° consist principally of fatty acids. The content of cyclic acids increases regularly with the b. p., so that acids b. above 268° (C_{10} acids) belong almost exclusively to the cyclic series. The consts. of the so-called lower naphthenic acids do not agree with those of acids with 5- and 6-C rings. The C_7 acid, heptanaphthenic acid, is really a mixt. of fatty and naphthenic acids. L. JACOVLIFF

The refining of light petroleum distillates. E. W. SHEEL. *Chem. Eng. Mining Rev.* **23**, 171–8(1929).—The predominating impurities in straight-run distillates are S compds. which in undue amts. cause corrosion, particularly of the brass and Cu fittings of the carburetor. Data are given to show that the S content of distd. fractions from any oil increases with rise in b. p. The chief chem. refining processes are described briefly, *i. e.*, the NaOH, Na plumbite, H_2SO_4, Frasch and Na hypochlorite processes. In the refining of cracked distillates desulfurization with the simultaneous removal of gum-forming diolefins is the objective. Acid treatment combined with sweetening is usually given these cracked distillates. A batch and a continuous treating system are described. D. F. BROWN

Report of Subcommittee XXVIII on autogenous ignition of petroleum products. A. H. NUCKOLLS, *et al.* *Proc. Am. Soc. Testing Materials* **30**, Pt. 1, 788–92(1930). As a result of coöperative tests on aviation gasoline, ordinary gasoline, Stoddard solvent, kerosene, motor oil, Et_2O, acetone, CS_2 and heptane, the results of which are given, minor changes in the tentative standard D-286-28T are suggested. It is recommended that the test be adopted as standard with these revisions and that further coöperative tests be made. D. F. BROWN

Atmospheric and vacuum distillation of Mid-Continent crude oil. JOHN PRIMROSE. *Refiner and Natural Gasoline Mfr.* **10**, No. 3, 69(1931).—The processes and equipment applicable to atm. and vacuum distn. are discussed. J. L. ESSEX

Physical properties of mineral oils and their investigation. I. THAMM. *Magyar Mérnök, Épiteszegylet Közlönye Havi Füzetei* **8**, 25–38(1931).—A general description S. S. DE FINÁLY

Refining shale oils with silica gel and with bauxite. II. Filtrations in liquid phase. B. SALADINI. *Industria Chimica* **5**, 1482–7(1930); cf. *C. A.* **24**, 2279; **25**, 2276.—Shale oils contg. as high as 9.58% S were filtered through silica gel, bauxite, mixts. of these, and also mixts. of each with decolorizing materials. Silica gel alone or with decolorants gives the best results, removing up to 30% of the total S, whereas bauxite removes up to 18–20%. Mixts. contg. bauxite, as well as the material itself, cause trouble in filtering, so that silica gel is preferable. A. W. CONTIERI

Black shale deposition in central New York. EDWARD W. HARD. *Bull. Am. Assoc. Petroleum Geol.* **15**, 165–81(1931). Lab. distn. tests of N. Y. black shales show the amt. of petroleum increases to the west, but with no corresponding increase in content of volatile matter, indicating that the petroleum was derived from org. constituents. The bituminous content of these shales seems to be directly related to the type of decompn. rather than to the type of org. material, and this particular type of decay existed only where the water was truly saline and toxic conditions were present. ALDEN H. EMERY

Discovery of oil in White Point gas field, San Patricio County, Texas, and history of the field. W. ARMSTRONG PRICE. *Bull. Am. Assoc. Petroleum Geol.* **15**, 205–10(1931). ALDEN H. EMERY

Heavy Dutcher oil in Bristow district, Oklahoma. CHARLES G. CARLSON. *Bull. Am. Assoc. Petroleum Geol.* **15**, 211–3(1931).—The gravity of most of the Dutcher oil produced in the Bristow district is 29–34° Bé. A new well gives oil of 18.3° Bé. asphalt 92, S 0.908, gasoline 6 and kerosene 2%. ALDEN H. EMERY

Development and production history on the Salt Flat and other fault fields of east central Texas. H. B. HILL, E. V. H. BAUSERMAN AND C. B. CARPENTER. Bur. Mines, *Rept. of Investigations* **3059**, 46 pp.(1931). ALDEN H. EMERY

New productive horizon in California. WALTER STALDER. *Bull. Am. Assoc. Petroleum Geol.* **15**, 201(1931). ALDEN H. EMERY

Can absence of edge-water encroachment in certain oil fields be ascribed to capillarity? J. VERSLUYS. *Bull. Am. Assoc. Petroleum Geol.* **15**, 189–200(1931).—Capillarity cannot hold the oil outside the depleted area around the well and cannot prevent

the edge water from moving toward the well. In the depletion zone, when the formation is an unconsolidated sand, 2 conditions are possible: the funicular, in which oil and generally gas flow freely, and the pendular, in which gas flows freely and may be followed by oil. If the oil-bearing formation is consolidated and the interstices are pores with narrowings, the Jamin effect would not stop the flow altogether because the gas would diffuse through the films of oil which shut off the pores in the narrowings. Light oils would evap. from one film and condense on the next nearer to the well.
ALDEN H. EMERY

Some effects of metamorphism on certain débris in source rocks. TAISIA STADNICHENKO. *Bull. Am. Assoc. Petroleum Geol.* 15, 161-4(1931).—Geodynamic alteration (carbonization) of the plant substances in the source rocks of petroleum results in raising the temp. of fusion and volatilization and in change in optical characters from isotropic to anisotropic.
ALDEN H. EMERY

Concrete coverings for pipe lines. J. F. HOUGH. *Oil and Gas J.* 29, No. 35, 62, 140, 141(1931).—From tests carried out under the most severe conditions, it was found that concrete-covered pipe resisted corrosion satisfactorily. The best results were obtained by using a concrete with less than 5 gal. of water per sack of cement. More water causes the concrete to disintegrate. Pressures of 1000 lb. per sq. in. did not give pressure cracks in the concrete coverings.
J. R. STRONG

The compression of hydrocarbon gases. I. N. BEALL. *Refiner and Natural Gasoline Mfr.* 10, No. 2, 99, No. 3, 154(1930). —The math. development of formulas pertinent to compression of gases is described. Calcn. of the percentage of liquefaction on compression, molal vol. of hydrocarbons, importance of compression before condensation for certain types of oil-absorption plants, compression at high pressures and multiple-stage compression are discussed. All gases become more compressible as their temp. is lowered and deviations from Charles' and Boyle's laws reach a max. at equil.
J. L. ESSEX

Safe-guarding cracking operations from accident. E. M. MATSON. *Refiner and Natural Gasoline Mfr.* 10, No. 1, 97, No. 2, 122, No. 3, 164(1931); cf. *C. A.* 25, 1066.—The hazards of water in a cracking system and the dangers arising from the corrosion of the equipment are discussed. Methods of preventing both occurrences are considered.
J. L. ESSEX

Manufacture of cracked tractor fuel. V. VALGIS. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* 1931, No. 1, 64–73; cf. *C. A.* 24, 2588.—Exptl. work is described.
V. KALICHEVSKY

Use of the new natural-gasoline specifications. S. S. SMITH. *Refiner and Natural Gasoline Mfr.* 10, No. 2, 90(1931).
J. L. ESSEX

Progress in distillation and fractionation. EARL PETTY. *Refiner and Natural Gasoline Mfr.* 10, No. 2, 67(1931).—The changes in distn. procedure due to the use of stabilizers are discussed and the use of vacuum in the distn. of heavier lubricating-oil fractions is described.
J. L. ESSEX

Pressure-distillate stabilization and gas-recovery systems. A. W. BURKET. *Refiner and Natural Gasoline Mfr.* 10, No. 3, 75(1931). —The essential factors are given by means of which the basic app. can be modified to suit any particular plant. For every vol. of propane removed from pressure distillate, 3.5 or more vols. of butane can be introduced without changing the vapor pressure. A complete description of the equipment necessary for combined stabilization and recovery is given.
J. L. E.

Chemistry of fuels greatest problem before refiner and motor builder. EARL BARTHOLOMEW. *Natl. Petroleum News* 23, No. 11, 72, 76, 79, 81, 82, 84, 85(1931).—The 2 variables most affecting the relative knock ratings are temp. and air-fuel ratio. Tests have shown that the single-cylinder test conditions give too high an antiknock value for benzene and some cracked gasoline.
R. W. KELLY

Chemistry of the doctor sweetening process. ARTHUR LACHMAN. *Ind. Eng. Chem.* 23, 354–7(1931).—L. verifies the 2 views that the PbS formed during the sweetening reaction reacts to form more plumbite and also acts as a catalyst when a sour gasoline is blown with air in the presence of Na plumbite soln. L. claims that Na_2S is also formed, which then oxidizes to $Na_2S_2O_3$. The sensitiveness of the doctor test was found to be 0.00006 molar concn. of mercaptan. The molar concn. of mercaptan in an av. sour gasoline was 0.01. Mercaptans can be oxidized with air alone in the presence of NaOH soln. or in the presence of fine inert solids, provided that the air stream is broken up into small bubbles. The quantity of Na_2S in alk. soln. contg. suspended PbS should be kept at a min. Air blowing assists in fulfilling this requirement. Finely divided free S should be added in the quantity detd. by analysis of the distillate for mercaptans.
J. L. ESSEX

Notes on adsorption. HAROLD J. TORMEY. *Refiner and Natural Gasoline Mfr.* **10**, No. 2, 78(1931).—A general discussion is given of the Freundlich and Langmuir equations for adsorption. J. L. ESSEX

Oil consumption and antiknock rating. H. R. STACEY. *Oil and Gas J.* **29**, No. 38, 26, 115(1931).—Errors in detg. knock rating due to different rates of oil consumption by leakage past the pistons are approx. one octane no. The error due to variation in temp. of the oil may be as much as one octane no. All knock-testing engines should be run with the oil consumption at the min. for the most accurate results. The oil temp. should be kept const. and as low as possible consistent with good lubrication J. R. STRONG

Porosity of non-friable substances. I. PREOBRAZHENSKIĬ. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* 1931, No. 1, 85-90.—The gravimetric method is the most reliable. Bitumen is extd. from the sample in a Soxhlet app. and the sample is satd. with kerosene under vacuum and weighed in the air. The exact procedure is described. V. KALICHEVSKY

Report of Subcommittee XXV on crankcase dilution. T. H. ROGERS, *et al.* *Proc. Am. Soc. Testing Materials* **30**, Pt. 1, 782–7(1930).—Results obtained on test samples by the tentative method D-322-30T are given. It is recommended that this tentative test be adopted. D. F. BROWN

The manufacture of grease. F. M. SIMPSON AND C. C. WILCH. *Refiner and Natural Gasoline Mfr.* **10**, No. 3, 77(1931).—Three general types of grease consisting of (1) admixts. of mineral oil and solid lubricants, (2) blends of residuum, waxes, uncombined fats, rosin oils and pitches and (3) soap-thickened mineral oils are discussed Na and K soap greases are highly sol. in water and have high m. ps.; Ca greases are insol. and unstable at high temps.; Pb and Zn soaps have low m. ps. and Al soap greases are stable at high temps. The soap is not so important as the mineral oil, which possesses the lubricating power. Types of equipment are described. J. L. ESSEX

Narrow operating temperature range improves lubricant performance. H. C. MOUGEY. *Natl. Petroleum News* **23**, No. 10, 32-D—32-H, 83(1931); cf. *C. A.* **24**, 2589. Oil consumption is kept at a min. by using oil of proper viscosity. The proper viscosity is detd. by actual performance and maintained by oil coolers. Max. viscosity is controlled by ease of starting. R. W. KELLY

Alignment chart for estimating viscosity-gravity constant of petroleum lubricating oils. W. F. HOUGHTON AND J. A. ROBB. *Ind. Eng. Chem., Anal. Ed.* **3**, 144–5(1931). An alignment chart is given for the rapid detn. of the viscosity-gravity const. as developed by Hill and Coats (*C. A.* **22**, 2834). Viscosity-gravity consts. of lubricating oil distillates from 14 crude oils are tabulated. D. F. BROWN

Evaluation and identification of mineral lubricating oils. B. MARSCHALKÓ AND I. BARNA. *Magyar Mérnök Épitészegylet Közlönye* **63**, 29–36(1929).—A practical method of evaluation consists in the detn. of the viscosity-temp. curve. The larger the value of $t''-t'$, or that of $t''-t'$ (*C. A.* **23**, 4053), the better the quality of oil, if the abs value of the viscosity reaches the required min. value at the working temp. The viscosity-temp. curve may be examd. by detg. 3 points: namely, the temps. belonging to the abs. viscosity values of 1.0, 0.1 and 0.025 poises. S. S. DE FINÁLY

The purification of mineral lubricating oils. M. J. PRELAZ. *Ind. olii minerali e grassi* **10**, 146–7(1930).—When the nature and phys. state of the impurities in mineral oils are known, the selection of the purification process is easy. Gaseous, liquid or solid materials that are sol., colloidal or insol. have to be eliminated. Water is sepd by drying in a vacuum without overheating; the O and some decompn. products are driven off also. On account of the very small quantity of impurities it is difficult to show their elimination by analysis. The oils lose their pungent odor and acidity. In some mineral oils, fibrils, dust, decolorizing earth and cryst. bodies of asphaltic nature are revealed by the microscope. Filtration is therefore necessary. Oxidation products that facilitate the alteration of the oil are still present. Centrifuging at a convenient temp. eliminates the water less completely than desiccation in a vacuum. Filtration eliminates the solid impurities in non-colloidal suspension. The cotton fibrils and org. dust are satd. with water and can be eliminated by centrifuging with the heavier particles. The sepn. of colloidal substances is effected by ultrafiltration. The elimination of the products dissolved in the oil is effected by using adsorbents. Properly chosen earths give satisfactory results. The above purification methods recondition used oils with sufficient safety. The following acidities were found: used untreated transformer oil, 0.062%; centrifuged, 0.077%; treated with 10% of earth and filtered, 0.008%; with 8%, 0.006%; with 5% earth and decanted, 0.028%; with 5% earth,

decanted and centrifuged, 0.026%; with 10% earth and decanted, 0.018%; and with 10% of earth, decanted and centrifuged, 0.018%. R. SANSONE

Raw materials and production of mineral lubricating oils. M. FREUND. *Magyar Mérnök Építészegylet Közlönye Havi Füzetei* 8, 1–10(1931).—A general description of present production methods. S. S. DE FINÁLY

Principles of chemical investigation of mineral lubricating oils. M. FREUND. *Magyar Mérnök Építészegylet Közlönye Havi Füzetei* 8, 18–25(1931).—A general description of research methods. S. S. DE FINÁLY

Regeneration of used lubricating oils. F. SCHNEIDER. *Azerbaidzhanskoe Neftyanoe Khozyaistvo* 1931, No. 1, 107–8.—Na_2SiO_3, NaOH and bleaching earth are almost equally satisfactory. V. KALICHEVSKY

Vacuum. GERRITT VAN DEN BERG. *Refiner and Natural Gasoline Mfr.* 10, No. 2, 88(1931).—A few schemes for preventing leaks are outlined. J. L. ESSEX

Report on coöperative work on the separation of cut-back asphalt. W. H. FULWEILER, *et al. Proc. Am. Soc. Testing Materials* 30, Pt. 1, 801–4(1930).—Coöperative results from the use of 2 different methods for sepg. cut-back asphalts to det. the amt. and character of both the base and the solvent are given. The first method is described in tentative specification D-20-28T. The second starts with atm. distn. and completes the distn. in a vacuum of not more than 10 mm. of Hg. The second method appears to have certain disadvantages. The work is to be continued and certain modifications suggested are to be tried. D. F. BROWN

Utilization of wood waste in the chemical industries. B. B. FOGLER. *Am. Soc Mech. Eng.*, Advance paper, Oct. 16–17, 1930, 4 pp.—Principal uses, other than for fuel, for wastes from saw-mill and wood-working industries are found in the following chem industries: destructive distn., manuf. of pulp, paper and building boards and those industries consuming large quantities of wood flour, principally the linoleum, plastics and explosives industries. The paper is intended to present a comparative summary of several outlets which chem. industries afford for salvage of waste from wood-working industries. E. I. S.

Wood chips. I. Motor oils from wood. OSKARI ROUTALA. *Acta Chem. Fennica* 3, 115–8(1930).—A review is given of the methods for cracking oils to obtain the lower fractions for use in gasoline motors. Lignite at 150–200 atm. and 450–80° yields about 80% of oily products, which yield considerable gasoline on cracking. When sawdust is treated with Cu, Fe and Co salts, and then with NH_4OH or NaOH, an impregnation with metallic hydroxides occurs. The latter are reduced to the free metal on treatment of the sawdust with H under pressure at 400–450°. Ni formate, NH_4 molybdates and chromates are also used as catalysts, a complete conversion of the sawdust to oily products resulting. At 260°, 50% conversion is obtained. On distn up to 350° the product gives water 4.45, oil 35.55, residue 52.10, gas 6.73 and loss 1.17%. Of the oil fraction, 74% distd. below 300°. Sawdust at 450° and 100 atm. with Zn and Cu catalysts gave 33% conversion to oils, of which 40% distd below 200°. Forty-five % of the weight of the wood was water-sol., with low acid but high MeOH content S. A. KARJALA

Dust explosions, with special reference to wood-working industries (BROWN) **24.** The radioactivity of oil-well waters (VERNADSKII) **3.** Cracking oil by electricity (ROWLAND) **4.** The content of Ra in oil-well waters in the district of Grozny (KHLOPIN, NIKITIN) **3.** Washing and bleaching clays of Azerbaidzhan (KOVALEVSKII) **18.** Apparatus for low-temperature distillation of oil shale (U. S. pat. 1,796,100) **21.** Pump and high-speed emulsifier system for bituminous materials (Brit. pat. 338,496) **1.** Refining oils (Ger. pat. 515,523) **21.** Detergents and lubricants containing fatty acid salts (Brit. pat. 338,919) **18.** Gel-like benzine (Hung. pat. 101,509) **13.** Gelatinizing organic liquids such as benzine (Brit. pat. 339,360) **13.**

Converting petroleum oils. ROY CROSS (to Gasoline Products Co.) U. S. 1,796,507 March 17. Oil is raised to a cracking temp. without substantial conversion (suitably by heating in a pipe coil in a furnace), the oil is collected in a substantial body and lighter fractions are distd. off in a vaporizing stage with refluxing and condensation of the vaporized material; unvaporized products are directed to a stagnant pool adapted to be heated to facilitate settling of free carbonaceous matter, the heavy settlings are withdrawn from the bottom of the pool and the liquid, relatively carbon-free oil, is withdrawn from a vertical restricted column in the pool so that turbulency in the oil body is prevented. App. is described.

Distillation of petroleum oils. ALEXANDER A. MACCUBBIN and JOSEPH ZAVERTNIK (to The Barrett Co.). Can. 309,219, Mar. 10, 1931. A method and app. are specified for distn. of petroleum at atm. pressure to produce distillate oils and residual oils. The residual oil is withdrawn during distn. while it is at approx. the temp. of the first distn. and immediately subjected to a high vacuum to effect further distn. of high-boiling oils by self-contained heat of the residual oil. The residue from such distn. is passed to a coke still maintained under high vacuum and distd. to coke, and the distillate is condensed under a high vacuum.

Apparatus for chilling liquids such as petroleum distillates to separate solids from them. HENRY TORRANCE (to Carbondale Machine Co.). U. S. 1,796,772, March 17. Numerous structural details are described.

Dehydrating emulsions such as those of petroleum. HAROLD C. EDDY (to Petroleum Rectifying Co. of Calif.). U. S. 1,796,750, March 17. Dispersed particles of the emulsion are mechanically agglomerated (suitably by the action of excelsior or steel wool) and the emulsion is subjected to the action of an elec. field. App. is described. Cf. *C. A.* **25**, 409.

Hydrocarbons. GENERAL TECHNICAL CO., LTD. Fr. 695,185, Aug. 20, 1929. Bituminous, and asphaltic compds., petroleum exts., tar exts. and natural waxes are submitted to a temp. of 360–440° under ordinary pressure in a retort provided with a system permitting the vapors to pass out to the condensers at a temp. between 170° and 250°, the speed of distn. being preferably such that the hourly amt. of distillate is always above 10% of the wt. of the capacity of the retort. Lighter hydrocarbons such as gasoline and kerosene are obtained.

Solidifying hydrocarbons. ROGER HOLTZMANN. Fr. 695,194, Aug. 22, 1929. Hydrocarbons, such as gasoline, petroleum and mazout, are solidified by incorporating therein, before or after heating, a binding agent, such as resin, suitably powd. and then adding while mixing milk of lime. The product is molded under pressure and hardened by immersion in water which preferably contains gallic acid.

Cracking hydrocarbons. I. G. FARBENIND. A.-G. Fr. 37,191, July 4, 1929. Addn. to 659,906 (*C. A.* **23**, 5312). Hydrocarbons of high b. p., such as mineral oils, tars, etc., are cracked under such conditions that a limited formation of benzine results, and the residue is afterward submitted to a hydrogenation under pressure, the untransformed fraction being submitted afresh to a cracking. Cf. *C. A.* **25**, 1666.

Cracking hydrocarbons. I. G. FARBENIND. A.-G. Brit. 339,274, May 30, 1929. Cracking of hydrocarbons in the gaseous or vapor phase is effected in the presence of a catalyst of pieces of Si (which may be molded from powd. Si and may be placed in a quartz tube) or Si deposited on a carrier. The material may be mixed with N, CH_4, water vapor, etc., and examples are given of the cracking of a mixt. of C_3H_8 and C_4H_{10} at 700° to form C_3H_6 and C_4H_8, and of the cracking of pentane, ligroin, paraffin and petroleum oils. It is stated that no carbon is deposited on the catalyst.

Cracking oils. CHARLES B. BUERGER (to Gulf Refining Co.). U. S. 1,796,138, March 10. Vapors are withdrawn under pressure from a confined body of oil heated under pressure, the pressure on the vapors is released and they are condensed, and the confined body of oil is replenished by oil heated under pressure and introduced under the surface of the body of oil while simultaneously permitting vapors from the preheated replenishing oil to mingle directly with vapors above the confined body of oil. Liquid oil is withdrawn from the main body of oil and mingled with the replenishing oil fed to the preheater App. is described.

Cracking oils. PANHANDLE REFINING CO. Brit. 339,291, June 29, 1929. Oil is preheated in a pipe coil and is then passed into a vaporizing zone, whence vapors are passed to a cracking coil, and the cracked vapors are fractionally condensed in a series of dephlegmators and fractionating columns by indirect heat interchange with make up oil or condensate. Various details of app. and operation are described. Cf. *C. A.* **24**, 3637.

Cracking oils. ROBERT E. WILSON and RICHARD J. DEARBORN. Can. 309,377, Mar. 17, 1931. A process and app. for converting higher-boiling oils into lower-boiling oils are specified. A stream of oil is heated in a coil under high pressure to a temp. sufficient to effect conversion; the heated oil is discharged into a conversion chamber maintained under a reduced pressure but substantially above atmospheric; the vapors thus formed are sepd. into several fractions by condensation; the residues from the conversion chamber are expanded into an expansion zone under a pressure below that in the chamber; a portion of the condensates resulting from the first-mentioned sepn. is returned to the heating coil at an intermediate point; another portion of the condensates is delivered into said expansion zone; fresh charge is introduced into said expan-

sion zone; and a fraction of the oil collected in said expansion zone is passed to the heating coil. Cf. *C. A.* **24**, 2594.

Vaporizing device (suitable for use with automobile engines) for catalytic decomposition or cracking of liquid fuels. D. BALACHOWSKY, P. CAIRE and M. LEVY. Brit. 339,251, July 26, 1929. Various structural details are described.

Refining hydrocarbon oils. ALEXANDER S. RAMAGE (to Gyro Process Co.). U. S. 1,796,621, March 17. S and Cl are removed from alc.-sol. hydrocarbon materials such as olefin and naphthene hydrocarbons or crude benzene by dissolving the materials in an alc. soln. of an alkali metal hydroxide, permitting the soln. to stratify and separately removing the purified oil and the alc. alk. soln. contg. impurities.

Purifying hydrocarbon oils with liquid sulfur dioxide. PAN AMERICAN PETROLEUM CO. Brit. 338,482, May 7, 1929. Materials such as lubricating oil, kerosene or various cracked distillates are treated at a temp. below 0° with liquid SO_2 and, after sepn., the partly purified oil contg. SO_2 is further treated, also at a temp. below 0°, with fuming H_2SO_4 and the purified oil is sepd. from SO_2 and sulfo acids. Numerous details of app. and procedure are described. Brit. 338,483 relates to a generally similar process in which, however, the H_2SO_4 used is not specified as being fuming acid. Brit. 338,484 describes a process of treating crude petroleum, shale or cracked oils with fuming or concd. H_2SO_4 in the presence of liquid SO_2 (simultaneously or previously added to the oil), preferably at a temp. not greater than the b. p. of SO_2, thus freeing the oils from polymerizable, unstable and S-bearing hydrocarbons. Various details of app. and procedure are given.

Treating hydrocarbon oils with aluminum chloride. JOHN L. COOLEY (to Standard Oil Co. of Calif.). U. S. 1,795,761, March 10. A hydrocarbon oil is mixed with $AlCl_3$ in a flowing stream at a temp. sufficient to cause reaction and formation of a relatively low-boiling product, the stream is passed to a flash zone in which vapors of low b. p. are sepd. from residual oil and $AlCl_3$, and a stream of the vapors and a sep. stream of the oil and tar are passed to a conversion zone in which the still heated vapors are again brought into contact with the oil-tar mixt. for agitating it and effecting further decompn. App. is described.

Apparatus for continuous vacuum distillation of hydrocarbon oils. KLAUS DREYER. Ger. 515,704, Nov. 1, 1927. Details of arrangement.

Separation of mixtures of hydrogen and hydrocarbon gases. W. K. LEWIS (to Standard Oil Development Co.). Brit. 338,719, Nov. 12, 1928. See Can. 305,734 (*C. A.* **25**, 788).

Purifying mineral oils. ALLGEMEINE GES. FÜR CHEMISCHE INDUSTRIE. Brit. 338,579, July 22, 1929. Material such as the total distillate from crude Persian petroleum up to 400° is treated with liquid SO_2 without previous fractionation, or the distillate may be freed from the benzine fraction b. up to 100° before treatment. The raffinate and ext. are freed from SO_2 and fractionated. Cf. *C. A.* **24**, 3109.

Adsorbent clay for decolorizing oils. ROBERT E. MANLEY and MERTON L. LANGWORTHY (to Texas Co.). U. S. 1,796,799, March 17. The clay is treated with a H_2SO_4 soln. of about 10% strength to improve its decolorizing properties.

Oven for dry distillation of bituminous shales, brown coal and similar materials. JOHAN G. GRÖNDAL and CARL L. CARLSON (to Patentaktiebolaget Grondal-Ramén). U. S. 1,796,264, March 10. Structural features of an app. with a perforated traveling grate.

Destructive hydrogenation. J. FOHLEN. Brit. 338,544, June 21, 1929. In the production of light hydrocarbons from materials such as anthracites, other coals, peat, wood, petroleum, asphalts or various org. vegetable or animal materials (or from products of pyrogenation of these), nascent H is produced from reacting material introduced independently into the reaction vessel (an example being given of the treatment of shale oil mixed with Fe and Cu shavings, introduced into an autoclave at 300° and 300 atm. pressure contg. an aq. soln. of a halide such as $AlCl_3.3NaCl$ for production of light oils). Reaction of water or steam on coke may also be used for obtaining nascent H. Cf. *C. A.* **24**, 1212.

Destructive hydrogenation. F. UHDE. Brit. 339,317, Oct. 3, 1928. Low-boiling hydrocarbons are produced from carbonaceous materials such as oils, bitumens, carbon, wood, etc., by heating them with finely divided or spongy iron and water in an autoclave to 400–500° with development of 200 atm. pressure during the reaction from the vapor pressure of the water, etc., present (the water reacting on the Fe to form H). The gases generated can be used to regenerate the Fe from the Fe oxide formed in the reaction, and hydrogenating catalysts such as Ni, Cu, ZnO or Zn chromate or splitting

catalysts such as $AlCl_3$ or reagents such as soda or potash also may be used. Various details of procedure are given.

Destructive hydrogenation. C. F. R. HARRISON, E. D. KAMM and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 338,576, July 16, 1929. In a 2-stage process for producing gasoline from heavy oil or coal (or a mixt. of coal and oil) by destructive hydrogenation, middle oil is isolated from the products of the first stage by fractional condensation and is subsequently treated with H in the vapor phase in the presence of a catalyst. The first stage may be carried out with use of a "massive" catalyst such as tin plate, and the middle oil may be treated in the presence of a similar catalyst or other catalysts such as Fe oxide, gels of oxides of metals such as Sn, Ni, Co, Fe or Mo or carbon black impregnated with Sn compds. Temps. of 420–80° and pressures of 100–250 atm. are suitable.

Gasoline production. FRANK A. HOWARD and NATHANIEL E. LOOMIS (to Standard Oil Development Co.). U. S. 1,797,145, March 17. Vapors such as those from petroleum oil are subjected to partial condensation to produce a first condensate requiring chem. treatment and a second condensate which requires no chem. treatment and has an end b. p. of about 150–75°; the second vapor is sepd. into liquid products substantially free of normally gaseous hydrocarbons and into a gas, the first condensate is chemically treated (suitably with H_2SO_4, alkali or "doctor" soln.) and the treated condensate is blended with the liquid products sepd. from the second vapor. App. is described.

Gasoline from natural gas. FRED E. HOSMER. U. S. 1,796,755, March 17. Various details of app. and procedure are described of a compression and cooling system for condensing relatively heavy and relatively light oils from natural gas, casinghead gas, etc., involving heat exchange between different materials in the treatment system. Cf. *C. A.* **24**, 955.

Filter for gasoline fed to engines. GEORGE B. INGERSOLL. U. S. 1,797,198, March 17. Structural details.

Preventing "knocking" in internal-combustion engines. A. J. DUCAMP. Brit. 338,780, Feb. 16, 1929. Hg cyanide is introduced into the engine (suitably as a dispersion of a soln. in glycerol or other suitable solvent with or without phenol, together with fatty acids or soaps such as Ca or Mg oleate as dispersing agents) The Hg cyanide may also be simultaneously introduced into the engine with the fuel or independently Cf. *C. A.* **24**, 496.

"Motor spirit" with added "anti-detonating" material. L. W. E. TOWNSEND and A. RICHMOND. Brit. 338,581, July 23, 1929. An "anti-detonating" ingredient is prepd. from shale oil or paraffin hydrocarbons or distillates from shale oil, petroleum or coal tar, which may be mixed with hydrocarbons of higher b. p. not normally suitable as motor fuel. *E. g.*, high-boiling shale oil is cracked and yields a liquid product which seps. into an upper layer of unchanged oil and a lower layer of tar; the tar is dehydrated at 120° in CO_2 and then distd. under reduced pressure in an inert atm. below 120° or distd. with wet steam below 120° and dried with a dehydrating agent.

Apparatus for cooling oil by direct contact with water. HEINRICH KOPPERS. Ger. 518,167, April 17, 1921.

Emulsions of tar oils, etc. VERKAUFSVEREINIGUNG FÜR TEERERZEUGNISSE G. M. B. H. (Fritz Bock, Georg Geisselbrecht and Josef Oberbach, inventors). Ger. 518,394, Aug. 3, 1926. Coal-tar oils are rendered directly emulsifiable with water by slightly oxidizing them, *e. g.*, with a little HNO_3. The oxidized oils may also be mixed with pitch, asphalt, tar, montan wax, etc., and the mixt. stirred with water to yield an emulsion.

Apparatus for separating bitumen from bituminous sandstone. S. F. PROSYANOV and V. V. PARFENOV. Russ. appl. 68,990, April 25, 1930. Structural details.

Purifying bitumen, pitch, tar, etc. D. ANDERSON & SON, LTD., and R. O. CHILD Brit. 339,470, Nov. 25, 1929. The material is dissolved in a solvent and a colloidal substance such as silicic acid is added; the impurities are allowed to settle and the purified soln. is then siphoned off and decanted and may be distd. The purified material may be used in the *manuf. of paints* or *in "electrical contrivances."*

Oxidation products of paraffin wax, etc. I. G. FARBENIND. A.-G. (Martin Luther and Hans Franzen, inventors). Ger. 518,389, Aug. 6, 1927. Addn. to 467,930 (C. A. **23**, 1748). The sepn. of the oxidation products from unaltered hydrocarbon as described in Ger. 467,930 is assisted by pressing the mass. The mixt. of oxidation products and unaltered hydrocarbons may first be saponf., and the unsaponifiable portion of the oxidation products then sepd. from hydrocarbon by warming and pressing.

Lubricant for internal-combustion engines. DANIEL P. BARNARD (to Standard Oil

Co. of Ind.). U. S. 1,796,857, March 17. A fluid lubricating oil is used with an addn. (suitably in the proportion of about 7%) of a relatively volatile and substantially non-inflammable diluent such as CCl_4.

Lubricant suitable for use in drawing and polishing metals. HERBERT L. JOHNSON (to Standard Oil Development Co.). U. S. 1,795,491, March 10. A salt (such as the Na salt) of a substantially water-sol. acid obtained from the sludge formed by treating petroleum lubricating oil with H_2SO_4 is heated together with water and a fatty oleaginous material such as tallow under such conditions as to effect distribution of the fatty material in the water.

Lubricating oil. WM. O. STEVENS (to Anti Hot Box Co.). U. S. 1,796,310, March 17. Dried wood ashes are immersed in lubricating oil in order to improve the oil, and the ashes and oil are then sepd.

Lubricating oils from petroleum. RED RIVER REFINING CO., INC. Ger. 515,840, Mar. 17, 1923. App. for distg. the petroleum *in vacuo* at 1–5-mm. pressure is described.

Apparatus for filtering lubricating oil. WM. W. NUGENT. U. S. 1,796,613, March 17. Structural features.

Bag filter suitable for filtering oil. WM. W. NUGENT. U. S. 1,796,532, March 17.

Regeneration of used lubricating oils. I. THAMM. Hung. 100,735, Dec. 20, 1929. An aq. emulsion is made of the changed part of the oils which can be sepd by sedimentation from the unchanged lubricating oil. Emulsification may be accelerated by adding carbonates or oxides of earth metals to the oil. The treatment with steam emulsifies the changed oil particles and carries away the fuel particles which were mixed with the oil. Grease can be made of the sepd. emulsion and the regenerated oil may be filtered and used again for lubricating.

Wood distillation plant. JOHN T. MYERS. U. S. 1,795,404, March 10. Various details of construction are described.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Some new processes for the separation of fibrous cellulose from plant substances. MELROSE ARNOT. *World's Paper Trade Rev.* 95, 961–4(1931).—An address in which are briefly discussed some of the most recently proposed pulping processes. A. P.-C.

Absorption of water vapor by cotton cellulose. ROBERT H. PICKARD. *J. Am. Chem. Soc.* 53, 1610–1(1931).—Polemical with Pidgeon and Maass (*C. A.* 24, 1974, 1155). Attention is called to work on the same subject at the Shirley Inst. C. J. WEST

Calculations and numerical data on the nitration of cellulose. L. SAUZAY. *Rev. gén. mat. plastiques* 7, 83–9, 139–45(1931).—Indications are given regarding the control of nitrating acids and the prepn. of mixts. of predetd compn A. P.-C.

Nitration of cellulose with phosphoric-nitric mixed acids (preliminary communication). E. BERL AND G. RUFFF. *Ber.* 63B, 3212(1930).—Nitration of cellulose with H_3PO_4-HNO_3 shows some marked contrasts with the ordinary H_2SO_4-HNO_3 nitration since H_3PO_4 does not sapon. cellulose nitrates, it is possible, with a suitably adjusted nitrating mixt. (slight excess of P_2O_5), to obtain readily cellulose nitrates with 14.0–13.7% N The nitration is accompanied by a marked swelling which facilitates the penetration of the HNO_3 into the interior of the fiber, resulting in a uniform nitration throughout. Unlike the product with much less N obtained with H_2SO_4-HNO_3, the cellulose nitrates prepd. with H_3PO_4-HNO_3 are perfectly stable after very short boiling; they contain no trace of mixed H_3PO_4-HNO_3 esters producing instability. Nitrates with 11–11.5% N cannot be produced in fiber form with H_3PO_4-HNO_3. In the nitration with H_3PO_4-HNO_3 the lattice of the native cellulose changes into that of hydrate cellulose, whereas with H_2SO_4-HNO_3 not too rich in HNO_3 the lattice of the native cellulose is retained in the nitrate. With H_3PO_4-HNO_3 the nitration is relatively slow, and it can be observed that the HNO_3 converts the cellulose into mercerized cellulose before esterification begins. With H_2SO_4-HNO_3 contg. not too much HNO_3, H_2SO_4 apparently enters the cellulose mol. as ester quite rapidly, and the sulfate then reacts to a greater or lesser extent with the HNO_3. Partially nitrated cellulose with the lattice of the native cellulose unchanged is no longer mercerized by H_3PO_4-HNO_3, *i. e.*, the lattice of the native cellulose is retained in such nitrates. The nitrates obtained with H_3PO_4-HNO_3 give a clear point diagram of cellulose trinitrate when the nitration and washing are effected under tension. Details of the expts. will be published elsewhere. C. A. R.

Viscosity of cellulose esters. I. The relation between concentration and viscosity of cellulose nitrate solution. KATSUMATA ATSUKI AND MASANORI ISHIWARA. *J. Soc. Chem. Ind., Japan* 33, Suppl. binding 506–8; *Caoutchouc & gutta-percha* 28, 15462–4(1930).—Cellulose nitrates were prepd. from spinning waste, cotton rag tissue and H_2SO_4 hydrocellulose, their viscosities being measured by a modified Ostwald viscometer. The relation between viscosity and concn. was found to be $\eta_s/\eta_0 = (1 + ac)^K$, where η_s and η_0 are the viscosities of the soln. and solvent, resp., c is the concn. yielding viscosity η_s, and a and K are consts. When the concn. of the ester is low, the viscosity follows Einstein's formula $\eta_s/\eta_0 = [1 + (5/2)f]$, where f is the vol. of the dispersed phase. When diln. is a max., swelling is diminished and the ester undergoes hydrolysis. **II. The viscosity of mixed cellulose nitrate solution.** *Ibid* 508–11.—When 2 kinds of cellulose nitrates of different viscosities are dissolved in a solvent, the total concn. of ester being const., the relation between the viscosity and concn. is $\eta_s/\eta_0 = [1 + a(nc' + c)]^K$, where c and c' are the concns. of the esters, a and K are consts. and $n = c'/c$.

P. S. BILLINGTON

Acetic acid recovery in the cellulose acetate industry. H. R. S. CLOTWORTHY. *Ind. Chemist* 7, 111–4(1931).—For every 100 lb. of cellulose treated there is available for recovery 558.5 lb. AcOH in a 15 to 40% soln. The procedures of converting to glacial AcOH by distn. with concd. H_2SO_4 or converting to Ac_2O by the action of SCl_2 are unsatisfactory because of the various chemicals necessary, the low yield, the necessary concn. of the soln. and the resulting high cost. Other processes employ a solvent of lower b. p. than AcOH, extg. the acid from its soln. and subsequently distg. off the solvent. These methods are not commercially satisfactory. A satisfactory method is described whereby a solvent of higher b. p. than the acid is used, the acid being fractionated from the solvent by distn.

P. S. BILLINGTON

Velocity of swelling of acetate film. Effect of swelling upon the mechanical properties of the film. KOTARO TANEMURA. *J. Soc. Chem. Ind. Japan* 33, Suppl. binding 497–9; *Caoutchouc & gutta-percha* 28, 15464–5(1930).—The velocity of swelling of acetone-sol. cellulose acetate in water is given by $x = (1/z)\log[W'_\infty/(W_\infty - W)]$, where W_∞ is the limit of swelling, W' the swelling at time z and x a const. Max. swelling was obtained in a 20% EtOH soln. The elongation of strips of the film under a given load was proportional to the degree of swelling.

P. S. BILLINGTON

Influence of plasticizer upon the mechanical properties of cellulose acetate film. KOTARO TANEMURA. *J. Soc. Chem. Ind. Japan* 33, Suppl. binding 499–500(1930).—The load-elongation curves of acetone-sol. cellulose acetate films prepd. from cellulose acetate in acetone and triacetin resemble those of cellophanes steeped in acetone-water mixts. The cellulose acetate film contg. triacetin shows both elastic and plastic elongation.

P. S. BILLINGTON

Some properties of cellophane and cellulose acetate film as dialysis membrane. Distribution of impurities in the case of recovery of waste soda from the viscose factory by the dialysis method. KOTARO TANEMURA AND SHIGEO MIYOSHI. *J. Soc. Chem. Ind. Japan* 33, Suppl. binding 432–4(1930).—The diffusion rates of certain acids and salts through cellophane were proportional to their diffusion coeffs., except for NaOH, the rate for which was twice as great as would be expected. LiCl diffused in larger quantities from an aq. soln. than when MeOH was present. The reverse was true of EtOH up to 75%. By proper manipulation waste NaOH from the viscose factory can be recovered from a mixt. of impurities by means of dialysis through cellulosic membranes.

P. S. BILLINGTON

Swelling of cellophane and rayon cloth by caustic soda solution and the effect of solutes upon the swelling. KOTARO TANEMURA AND SHIGEO MIYOSHI. *J. Soc. Chem. Ind., Japan* 33, Suppl. binding 431–2(1930).—A circular sheet of com. cellophane became elliptical when immersed in 6.12% NaOH. The contraction occurred in the direction in which the tensile strength of the air-dry sheet was greatest, and elongation least. Max. swelling of cellophane occurred in 10% NaOH. Rayon cloth disintegrated in 8–13% NaOH. Swelling decreased with addn. of solutes.

P. S. BILLINGTON

Lilienfeld rayon. ERNST GEIGER. *Helv. Chim. Acta* 13, 1114–6(1930).—Polemical with Hans E. Fierz-David and August Brunner (*cf. C. A.* 24, 967, 3643). G. concludes that F.-D. and B. discussed earlier mfg. weaknesses which are no longer characteristic of Lilienfeld rayon.

C. H. PERI

New method for the recovery of viscose spinning bath. I. Rapid method for analysis of sodium sulfate in spinning bath. KOTARO TANEMURA AND SHIGEO MIYOSHI. *J. Soc. Chem. Ind., Japan* 33, Suppl. binding 323–4(1930).—The temp. at which $Na_2SO_4.10H_2O$ begins to crystallize is detd., and the percentage of salt in the bath is found

from a previously prepd. chart. **II. Specific heat of Glauber's salt.** KOTARO TANEMURA. *Ibid* 324–5.—The mol. heat of H_2O of crystn. of $Na_2SO_4.10H_2O$ was calcd. as 9.6 cal. The mean mol. heat of H_2O of crystn. was detd. to be 9.6–9.8 cal. The mol. heat of $Na_2SO_4.10H_2O$ was calcd. as 128.2 cal. and the sp. heat of the crystal at 25° as 0.40. **III. Properties of sodium sulfate.** KOTARO TANEMURA AND SHIGEO MIYOSHI. *Ibid* 330–1.—A summary of the physicochem. characteristics of Na_2SO_4 is given. H_2SO_4 lowers the transition temp. and increases the soly. of $Na_2SO_4.10H_2O$, *i. e.*, it lowers the crystn. temp. of the salt. $MgSO_4$ at first lowers the crystn. temp. of $Na_2SO_4.10H_2O$, but increasing $MgSO_4$ concn beyond a certain limit increases the crystn. temp., the solid phase then being $MgSO_4.7H_2O$. With a normal viscose spinning bath for centrifugal systems, the salt which crystallizes out on cooling is always $Na_2SO_4.10H_2O$, completely free from Na_2SO_4 and $NaHSO_4$. It forms no double salts with $ZnSO_4$, $FeSO_4$, $MnSO_4$ or $CuSO_4$, which accumulate in the bath. **IV. Dehydration of Glauber's salt.** KOTARO TANEMURA, SHIGEO MIYOSHI AND MIZUKI YOSHIDA. *Ibid* 332–3.—The vapor pressure of the system $Na_2SO_4.10H_2O \rightleftharpoons Na_2SO_4 + 10H_2O$ at 25° is 18.4 mm. Hg. The hydrous salt can be dehydrated in a closed chamber by circulating air dried with concd. H_2SO_4 and NaOH. It also can be dehydrated by treating with twice its wt. of 92% EtOH, or with concd. caustic; 45.8 g. with 100 g. 50% NaOH soln. yield 21 g. Na_2SO_4. Heating to the transition temp., centrifuging, cooling to 5° and centrifuging 3 times yields 31.95 g. Na_2SO_4 from 100 g. $Na_2SO_4.10H_2O$. If 36.3% of the wt. of the decahydrate is added as solid NaOH at the transition temp., the salt is dehydrated. **V.** KOTARO TANEMURA AND SHIGEO MIYOSHI *Ibid* 333–4. In the *method of sulfate recovery* patented by the authors 0.9 kg. Na_2SO_4 and 4 kg. H_2O are assumed to accumulate as spent bath per 1 kg viscose rayon; 0.9 kg. Na_2SO_4 combines with 1.1 kg. H_2O on cooling. When 2.3 kg. anhyd. Na_2SO_4 is added to the spinning bath, and 7.3 kg. of the decahydrate is removed on cooling, both 0.9 kg. Na_2SO_4 and 4 kg. H_2O are at the same time removed. The necessary equipment, crystallizer, hydroextractor and dehydrator, lasts much longer than an evaporator and is more efficient from the standpoint of heat utilization.

P. S. BILLINGTON

Manufacture of artificial silk. Spinning of viscose. H. L. DE LEEUW. *Tech. moderne* **22**, 521–9, 623–7, 720–4(1930); cf. *C. A.* **24**, 3643.—A detailed description is given of the methods and app. used and methods of producing artificial silk other than viscose.

P. THOMASSET

Studies on lignin and related compounds. VII. A kinetic study of the action of hypochlorous acid on spruce lignin and its bearing on the constitution of the spruce lignin molecule. HAROLD HIBBERT AND K. AUSTIN TAYLOR. *Can. J. Research* **4**, 240–53(1931); cf. *C. A.* **25**, 2010.—The action of HClO on glycol lignin in finely divided aq. suspension, and in alk. soln., is autocatalytic; the autocatalysis is due to formation of HCl, which catalyzes the reaction strongly. Apparently HNO_3 acts only by increasing the concn. of undissocd. HCl. The effects of HCl may be a direct catalytic effect or undissocd. HCl or may be due to formation of Cl. A comparison of the amts. of HClO absorbed and HCl formed by methylated and unmethylated lignin indicates that if ketomethylene groups are present in lignin, they do not enolize sufficiently to play an appreciable part in the rapid reaction between HClO and lignin. The rapid absorption of HClO by lignin dissolved in alkali indicates that there is probably about 15% of a phenol nucleus in lignin. This value is supported by the rapid absorption by lignin, dissolved in alkali, of Br from Br water at very low concns. and is based on the assumption of only 1 atom of halogen entering the phenol nucleus, which is true with vanillin. If 2 or 3 atoms enter the nucleus, this value of 15% must be divided by 2 or 3. It represents in any case a max. value. The phenol nucleus accounts for only 1/3, or less, of the total rapid HClO absorption. The remainder is probably due to addn. of HClO to an ethylene linkage, chlorination of a phenol ether or a combination of both reactions.

Alpha- and beta-lignosulfonic acids. PEDER KLASON. *Svensk Pappers-Tid.* **34**, 118–9(1931); cf. *C. A.* **25**, 1077.—K. gives the analytical data on which he based the formula $3C_9H_{10}O_3 + H_2SO_3 + C_{18}H_8N - H_2O$ (cf. *C. A.* **24**, 3358) and states that he has also succeeded in making the tetraconiferyl aldehydes.

WILHELM SEGERBLOM

Some notes on the recovery of soda. J. A. WALKER. *Proc. Tech. Sect. Paper Makers' Assocn. Gt. Brit. Ireland* **11**, Pt. 1, 186–202(1930).—A good recovery of soda can be obtained only if an adequate proportion of black liquor is forthcoming at a strength and vol. which can be efficiently dealt with. The factors effecting this are discussed. The black liquor must be reduced to such a consistency as will permit a const. combustion in the rotary. The factors on which the efficiency of the evaporator depend are discussed. Troubles which may arise in the system are described. The rotary is

discussed. The causticizing process is dealt with in some detail, and strict control is urged. P. S. BILLINGTON

Soda process studies. III. Action of alkali solutions on sulfite pulp. J. H. ROSS AND C. R. MITCHELL. *Research Notes* **3**, 21–3(1930); *Pulp Paper Mag. Can.* **31**, 402–3, 414(1931); cf. *C. A.* **24**, 4153.—When bleached sulfite is treated in a rotary digester for 3 hrs. with NaOH solns. at 150–80°, the concn. of alkali (over the range 1–7%) at temps below 160° has but little effect on the quantity of material dissolved and on the α- and β-cellulose contents of the residue; at higher temps. the effect of concn. is much more marked. For every temp. there is an optimum concn. of alkali which produces a residue of max. alkali resistance and a concn. of alkali which produces a max. of bulking properties in the fiber. The fluidity of solns. of the treated pulp increases regularly as the temp. of digestion and alkali concn. are intensified. A. PAPINEAU-COUTURE

Bleaching studies. I. An integrating attachment for the Hess-Ives tintometer. F. H. YORSTON. *Research Notes* **3**, 11–3(1930); *Pulp Paper Mag. Can.* **31**, 338–9, 360(1931); cf. Ross, Mitchell and Y., *C. A.* **25**, 1078.– The Hess-Ives tintometer has been supplied with a device for intensifying the tint of nearly white materials by multiple reflection of light at the surface of the material. By its use differences between the reflection factors of different bleached papers, measured through any particular color filter, are magnified 2–3 fold. Further, since the magnification increases with the value of the reflection factor, differences in hue are greatly accentuated. **II. Measurement of hydrogen-ion concentration of bleach liquors with the glass electrode.** *Research Notes* **3**, 15–6(1930); *Pulp Paper Mag. Can.* **31**, 374–5(1931).—Consistent and accurately reproducible measurements of the H-ion concn. of bleach liquors can be made with the glass electrode and a vacuum-tube potentiometer. HOCl acts as a buffer in bleach liquors within the range of p_H 6.5–8.5. A. PAPINEAU-COUTURE

Estimation of wood pulp in paper. E. DEBENEDETTI. *Boll. staz. sper. carta e fibre tessili vegetali* **9**, 134–7(1930).—The chem. methods for detecting and detg. wood pulp in paper utilize reactions for cellulose and lignin. The lignin content varies with different wood pulps, but av. values have been detd. for the woods and celluloses used in papermaking, and from these values can be calcd. approx. the wood or mechanical pulp contents in a paper when jute and manilla are absent. Reagents used are: (*a*) 1 g phloroglucinol, 500 cc. alc., 25 cc. concd. HCl; (*b*) 5 g. aniline sulfate, 100 cc. distd water, 1 drop H_2SO_4; (*c*) dimethyl-*p*-phenylenediamine. Their use is limited to white or light-colored papers. The quantity of lignin is detd. (1) directly by liberating from the cellulose and weighing, (2) by measuring the consumption of certain chemicals absorbed by the lignin substances, (3) by dissolving the lignin with suitable agents, weighing the residual cellulose, and calcg. the lignin by difference. Many methods use the hydrolysis of cellulose with strong acids that under proper conditions do not attack the lignin, which can be dried and weighed. H_2SO_4, HCl and HNO_3 alone, or together or with dehydrating agents, have been proposed. Cl, Br, phloroglucinol and $KMnO_4$ also are used for detg. lignin. R. SANSONE

Pulping with chlorine. I. Pulping bagasse. J. KAWAMURA. *J. Soc. Chem. Ind.*

Japan **33**, Suppl. binding 392–5(1930).—Air-dry bagasse contained moisture 12.55, C_6H_6 ext. 0.94, alc. ext. 1.99, H_2O ext. 2.84, 1% NaOH (hot) ext. 29.0%. The NaOH-extd. residue contained ash 3.5, lignin 22.3, cellulose (Cross and Bevan) 43.4, pentosans 27.4%. The cellulose contained 69.9% α-cellulose and 9.3% pentosans. Bagasse after extn. with 0.5, 1.0 and 2.0% NaOH was chlorinated at about 50% consistence, the change in yield, lignin, pentosan and ash being followed. The more drastic the alk. pre-treatment, the lower were the yield and lignin content for an equal Cl consumption. The pentosan content remained fairly const. at 31–33% of the chlorinated material. Of this, ½ was removed by treating for 12 hrs. with cold 10% NaOH, 7% cellulose being likewise removed. II. Reactions of chlorine. 1. *Ibid* 396–8.—The ratio of Cl as HCl to organically combined Cl formed in chlorinating ligno-celluloses has been variously reported from 1:1.3 to 1:0.4. K. extd. bamboo with alc.-benzene and 1% NaOH, chlorinated, washed and extd. the residue 3 times with 1% NaOH. HCl was detd. in the wash water, after expelling free Cl, while organically combined Cl was detd. by heating the NaOH ext. at 250° and detg. as NaCl. The ratio of acid to organically combined Cl was 1:0.4. III. Reactions of chlorine. 2. *Ibid* **34**, Suppl. binding 62–4(1931).—Results similar to those reported above for bamboo were obtained with bagasse. When a large excess of Cl was allowed to act on the bagasse for a long time, the ratio of HCl to org. chlorides was slightly increased, indicating an oxidation.

M. HEINIG

The technic of purifying pulp: effect of calcium lime in the production of a bleached sulfite with a high α-cellulose content. G. P. GENBERG. *Pulp Paper Mag. Can.* **31**, 199–210, 219(1931).—By cooking bleached or partly bleached sulfite pulp with lime, the α-cellulose content of the final residue is increased appreciably, accompanied by a loss in wt. depending principally on the original α-cellulose content. More than 5–10% CaO has no beneficial effect on the final results and on the loss in wt. of the pulp. More than 70% of the total increase in α-content is effected in the first 4 hrs. at the consistency (4.5%) and temp. (100–40°) used. The most important factor is the initial α-cellulose content, and in order to obtain, under most economical conditions, a final pulp with a max. α-content, it is necessary to start with a pulp so treated that a max. α-content is retained before the CaO treatment is begun. A multiple treatment with CaO has no increased effect on the α-cellulose content, but produces addnl. loss in wt. By omitting washing after bleaching and by starting the CaO treatment immediately after exhaustion of the bleach, a higher α-cellulose content is obtained. Practically the same α-cellulose content is obtained by treatment with 10% CaO and with 5% NaOH, but the CaO-treated pulp has a lower Cu no. and suffers a higher loss in wt. The optimum conditions for max. α-cellulose, min. bleach consumption and min. shrinkage were: Unbleached sulfite is given a preliminary bleaching with a ratio of 35% bleach powder to Roe Cl no. of 2:1, treated with CaO, washed and given a final bleaching to a full white color with a 0.75:1 bleach:Cl no. ratio. If the ratio of bleach to Cl no. is controlled at 2.0:1, the final α-cellulose content will be independent of the Cl no. of the unbleached pulp, but the shrinkage will be higher with increased Cl no. The use of MgO lime instead of Ca lime is of no advantage. The time to exhaust the bleach is prolonged, and a lower α-cellulose content is obtained when the CaO is added to the pulp at the same time as the bleach liquor and when the bleaching action is allowed to take place in the presence of the CaO. Com. trial runs made by the procedure developed in the lab. produced a sulfite pulp with high α-cellulose content. Sulfate pulp is not affected to any extent by either CaO or NaOH under the conditions applied to sulfite pulp in the investigation. A. P.-C.

The Rosen process for the production of sulfite pulp from resinous woods. E. MEUNIER. *Papeterie* **53**, 214–8(1931).—A brief discussion of the process and its merits. The difficulties encountered in pulping resinous woods by the sulfite process have been shown to be due to the fact that the compn. of the resin acids in the heartwood apparently differs from that of the resin acids in the sapwood. Rosen overcomes the difficulty by a preliminary treatment of the chips in the sulfite digester with a weak alk.-earth soln. for 2–5 hrs. at a temp. of up to 110°, followed by washing with salt soln.; this treatment can be repeated if necessary; the chips are then treated with SO_2 gas, and are then subjected to the usual low-temp. sulfite cooking, yielding a very pure pulp, low in ash and contg. up to 92.4% of α-cellulose, which can be bleached with 2.5–4% available Cl.

The childhood of paper making, as illustrated by Kashmiri methods of the present

day. W. RAITT. *Proc. Tech. Sect. Paper Makers' Assocn. Gt. Brit. Ireland* **11**, Pt. I, 21–52(1930); cf. *C. A.* **24**, 1975.—Historical. Twenty-five photographs of great interest to the modern paper maker are given. P. S. BILLINGTON

Fundamental research and the paper industry. T. TREVOR POTTS. *Proc. Tech. Sect. Paper Makers' Assocn. Gt. Brit. Ireland* **11**, Pt. I, 115–29(1930).—A résumé is given of past fundamental investigations and the suggestions of some problems for future study. P. S. BILLINGTON

What patents mean to the paper technologist. JOSEPH ROSSMAN. *Paper Trade J.* **92**, No. 14, 58–60(1931).—R. describes the classification system of the U. S. Pat. Office, outlines the patent holders' rights, interprets the validity of claims, discusses the sulfate process patent of Eaton and Dahl and shows the advantages of patent protection. A. PAPINEAU-COUTURE

The development of paper manufacture from southern pines. R. H. STEVENS. *Paper Ind.* **12**, 2019–26(1931); cf. *C. A.* **25**, 590.—A general discussion of the advantages and possibilities of the Southern U. S. for the production of pulp, particularly kraft, and paper. A. PAPINEAU-COUTURE

The formation of paper. W. BOYD CAMPBELL. *Research Notes* **3**, 1–3(1930); *Pulp Paper Mag. Can.* **31**, 424–5, 438(1931).—An address dealing particularly with the qualities of pulp which make it suitable for paper. The adhesion of cellulose to cellulose is particularly stressed, and C.'s theories as to the mechanism of the so-called hydration by beating (*C. A.* **24**, 1976) are explained. A. PAPINEAU-COUTURE

Corrosion reduced by new constructional materials. JAMES A. LEE. *Paper Trade J.* **92**, No. 12, 67–8(1931).—A discussion of the merits and possibilities of alloy steels (particularly 18–8 alloy and others of the same type) and of C in the sulfite and paper industries. A. PAPINEAU-COUTURE

Simple electrometric methods of analysis in the paper mill laboratory. T. TREVOR POTTS. *World's Paper Trade Rev.* **95**, 1037–8(1931).—Callan and Horrobin's app. (*C. A.* **23**, 789) did not give good results for alkalimetric work with the circuit in the original form suggested by C. and H.; inserting a potentiometer across the output of the transformer allows of much better control of the voltage of the input to the electrodes, enables better adjustment of the initial reading of the measuring instrument, and prevents damage to the latter if the soln. under examn. happens to be of high cond. The outstanding use of this method in the paper mill lab. is the examn. of highly colored caustic liquors; but it is also applicable to other titrations, such as sulfates with BaCl$_2$ and pptn. of size by alum. Attention is drawn to the effects of the presence of dissolved CO_2 in ordinary distd. H_2O on the potentiometric detn. of H-ion concn. For ordinary paper mill work, direct detn. on the stock taken from the mixing box or stuff chest is preferable to extn. of paper with distd. water. The quinhydrone electrode used in conjunction with the satd. calomel electrode is by far the most useful in the paper mill lab. A. PAPINEAU-COUTURE

Notable recent improvements to high-speed paper-making machines. S. RICHARDSON. *Proc. Tech. Sect. Paper Makers' Assocn. Gt. Brit. Ireland* **11**, Pt. I, 131–43(1930). The increased production from paper machines has been due to increased paper speed, increased wire width, and reduction of over-all mfg. costs. These 3 factors are discussed in some detail. P. S. BILLINGTON

The application of electrical power in paper mills. JAMES R. HAPPER. *Proc. Tech. Sect. Paper Makers' Assocn. Gt. Brit. Ireland* **11**, Pt. I, 164–79(1930).—The a. c. and d. c. systems are compared. The placing of a beater-drive motor inside the beater-roll has worked out very satisfactorily. The merits of steam *vs.* electricity are discussed. P. S. BILLINGTON

The testing of condenser paper. F. L. ROMAN. *Proc. Am. Soc. Testing Materials* **30**, Pt. II, 1012–24(1930).—A discussion is given of the relationship between several characteristics of condenser paper made from linen stock and the dielec. strength (breakdown voltage) of the condensers wound with this paper. Variations in the density of the condenser paper have no noticeable effect on the dielec. strength of the corresponding condensers. It is shown that, when in small nos., conducting paths through the paper have no important effect on the dielec. strength of condensers wound with 2 sheets of the paper between tinfoils, but the percentage of "shorted" condensers or of condensers failing at very low voltages may be expected to increase approx. as the square of the no. of conducting paths per unit area of the paper. Variations in the porosity of the paper are shown to have marked influence on the dielec. strength of the corresponding condensers and *porosity requirements* are suggested for papers used in low-voltage condensers and for papers used in high-voltage condensers. P. S. BILLINGTON

Variability in results met with in paper strength testing. CYRIL V. OLIVER. *Proc.*

Correlation of bursting strength and tensile strength of paper. JAMES STRACHAN. *Proc. Tech. Sect. Paper Makers' Assoc. Gt. Brit. Ireland* **11**, Pt. I, 86–114(1930); cf. *C. A.* **24**, 5485.—A math. treatment of the subject, and a discussion of the formulas obtained by various investigators. The methods of calcn. indicated give a means of investigating the degree of cohesion produced between the fibers by papermaking operations, as reflected by the bursting test. A voluminous discussion is included. P. S. B.

The coloring of paper. N. L. MATHEWS. *Proc. Tech. Sect. Paper Makers' Assoc. Gt. Brit. Ireland* **11**, Pt. I, 144–63(1903); cf. *C. A.* **24**, 5486.—A description of the nature and source of natural vegetable dyes and pigments is given. The theory of the org. constitution as related to color is briefly discussed, and the theory of dyeing is touched upon. The characteristics of direct or substantive, basic, and vat dyestuffs are discussed. The cause of two-sidedness is explained, and the reason for adulteration of the dyestuffs is discussed. P. S. BILLINGTON

Classes of color used in the dyeing of paper. HAROLD E. PRATT. *Paper Trade J.* **92**, No. 14, 57(1931).—A brief review of the application of basic, acid and direct dyes and pigments to paper coloring. Their limitations are pointed out. A. P.-C.

Further study of paper-coating minerals and adhesives. MERLE B. SHAW, GEORGE W. BICKING AND MARTIN J. O'LEARY. *Bur. Standards J. Research* **5**, 1189–1203(1930); *Paper Trade J.* **92**, No. 14, 52–7(1931); cf. Hamill, Gottschalk and Bicking, *C. A.* **19**, 175; **20**, 1519; **21**, 175.—American clays examd. compared favorably with foreign clays as paper-coating minerals and produced good printing qualities. Diatomaceous earth compd. did not adhere well to the base paper. The modified starches used did not appear to have as strong adhesive qualities as casein or glue. Graded according to their clay-suspending property, the adhesives were in the following descending order: starch, casein, glue. Chem. analyses, color measurements and settling data for the minerals used are given. A. PAPINEAU-COUTURE

Animal and vegetable adhesives for paper manufacture. GIULIO C. CIOCCHI. *Ind. carta e arti grafiche* **33**, 265–8, 512–3(1930).—The manuf. of glue from bones, hides, etc. is described. The material generally employed in paper manuf. is obtained from the fleshy side of hides, butcher's residues, hide cuttings, and calf and mutton heads. Animal glue is a positive colloid; its solns. represent dispersed systems with a very fine phase. The reaction of the gelatin must be nearly neutral, since the presence of acids reduces and hinders its fixation in paper. Microörganisms transform gelatin into an unfixable product. SO_2 eliminates this danger. A good glue absorbs 10–12 parts of water. The value of glue depends on the water and ash contents, m. p., viscosity, swelling capacity, fatty matter, acidity, mineral impurities, the elastic force and adhesive power, all of which are influenced by the p_H. Gelatin has two max. swelling points in water, p_H = 2.4 and p_H = 11.6, and has a min. swelling point at p_H = 7.7. In the hydrolysis of ossein there is a min. between p_H 4.7 and p_H 6; the reaction proceeds well with formation of a good product at p_H = 3–4. The decompn. of gelatin into proteoses and peptones follows in a 2nd hydrolysis; it is not strong between p_H = 3 and p_H = 8, but takes place beyond this. To avoid hydrolysis during the evapn., the soln. is brought to p_H = 4.7. Casein must be produced under conditions that effect coagulation in an acid medium with p_H = 4–4.1. At this hydrogen-ion concn. is obtained a product contg. the min. quantity of salts. The greatest yield with starch pastes is below 100°, above that temp. alteration follows. Stayco gum is starch solubilized by oxidation; Osalon and Vosgeline are farina treated with O_3. Dextrin prepd. with farina gives a limpid water soln. not obtained with starch from cereals. The cohesive power of dextrins decreases with the increase of their soly in cold water. Gums are not well-defined chem. products. Kordofan gum destroys the capillarity of water solns., having the same viscosity in cold and warm solns. Gum arabic solns. of 20° Bé. are used in paper making. Gum Senegal is less sol. in water than gum arabic, and its more viscous and gelatinous solns. sep. the gum more easily with many chemicals. R. SANSONE

Finishing, processing and converting of paper. NORMAN CLARK. *Paper Trade J.* 92, No. 13, 53–5(1931).—After a brief summary of developments in the field of finishing, processing and converting paper during the year 1930, the Tech. Assoc. of the Pulp and Paper Industry literature relating to coated and processed papers is reviewed. A. PAPINEAU-COUTURE

The porosity of paper. GIRO SILVIO. *Papier* **34**, 173–81(1931); cf. *C. A.* **24**,

6011.—The effects of the thickness of the sheet and the pressure on the detn. of the porosity are studied. The tests were carried out on 100% soda, unloaded and uncalendered paper, all the samples being made from the same beaterful of stock to eliminate possible differences in degree of beating and sizing. *Effect of thickness:* (1) The time required for the passage of a given vol. of air through the sheet does not vary directly with the thickness, at least above a certain thickness, which might be called the limiting thickness. (2) Above the limiting thickness, the time is practically const. for a given pressure. *Effect of pressure:* By defining the impermeability as the reciprocal of the porosity and calcg. it from the formula $pt/2$, in which p is the pressure and t the time, it was found to be an essentially variable property, increasing with the pressure at which it is detd. but varying only slightly above a certain pressure. As it has been suggested that the impermeability is rather a function of $\sqrt{p}$, it was calcd. from the formula $t \times f(\sqrt{p})$ but was found to be even more variable when expressed in this form. An attempt to find a formula which would give a practically const. value for the impermeability at different pressures led to the formula $I = t/2 \times p^{0.938}$; but even this did not give absolutely const. values. It is therefore considered preferable always to carry out the detn. at a definite pressure, which should be selected either in the zone where small variations in p lead to small errors in t, or in the zone of utilization of the paper.

MILLIKEN (to Hercules Powder Co.). Brit 338,941, May 29, 1929. In an app. of the character described in Brit. 301,267 (*C. A.* **23**, 4071), the material is forced under pressure together with water through a restricted passage such as a coil (which may be formed of chrome steel of small diam. and a length of 2500–3000 ft.) which leads directly or through a suitable valve to a stand-pipe or chamber to effect substantial equalization of pressure in the coil between the inlet and discharge ends. The coil may be heated by steam to 130–160°. Various details of app. and operation are described.

Apparatus for saponifying cellulose acetate. VEREIN FÜR CHEMISCHE INDUSTRIE A.-G. (Karl Werner, inventor). Ger. 515,779, Aug. 12, 1928.

Cement for films. M. SÁRY. Hung. 100,689, Oct. 3, 1929. Ten g. celluloid is dissolved in 5000 g. acetone and 500 g. amyl acetate, and 10 g. AcOEt is added.

Bleaching tower for fibers, especially cellulose. PAPER PATENTS CO. Ger. 515,-961, Nov. 30, 1928.

Bleaching unspun fibers. PAPER PATENTS CO. Ger. 515, 731, Aug. 5, 1928. The bleaching of raw material, especially cellulose, for paper manuf. is described.

Modifying the luster of rayon at the time of production. H. DREYFUS. Brit. 338,490, May 17, 1929. In making filaments or other products from various specified cellulose esters or ethers, a reduced or modified luster is obtained by adding to the solns. used for dry or wet spinning a small proportion (suitably 0.5–2%) of finely subdivided insol. materials (preferably white pigments) such as $BaSO_4$, Pb sulfate, ZnO, Ba phosphate, $ZnCO_3$, $CaCO_3$, $MgCO_3$, $CaSO_4$, Al_2O_3 or silica, and, to minimize settling, materials of low sp. gr. may be added such as Li and Mg silicates; oils, dispersing agents, etc., also may be used. The use of alkyl and aralkyl ethers of starch also is mentioned, and various details and modifications of procedure are described.

Artificial silk from viscose. I. G. FARBENIND. A.-G. (Adolf Kämpf and Arnulf Hager, inventors). Ger. 518,234, Apr. 27, 1929. Artificial silk of reduced luster is prepd. by spinning viscose solns. to which a small quantity of a stannate or antimonate, particularly a pyroantimonate, has been added. The added salt is decompd. during the spinning process, with the result that colloidal metal oxide is deposited in and on the fibers. An example is given.

Artificial silk, etc. LÉON LILIENFELD. Fr. 37,344, July 31, 1929. Addn. to 666,178 (*C. A.* **24**, 1509). Artificial threads of a high resistance in the dry state, above 2 g. per denier, are made by coagulating a thread of viscose by means of a gaseous mineral acid.

Artificial silk spinning. HANS EGGERT. Ger. 515,871, July 14, 1926. The adhering pptg. bath is removed from spun artificial silk fibers by suction-washing the fibers after they are wound on spools.

Artificial filaments, ribbons, etc. BRITISH CELANESE, LTD., R. P. ROBERTS and L. W. GREGORY. Brit. 338,936, July 29, 1929. Opaque products formed from org. esters or ethers of cellulose coagulated with aq. media are given improved transparency and tensile strength by heating them (suitably with dry steam or other hot gases or vapors while under tension, and if desired after preliminary impregnation with solvents, swelling agents or plasticizers). Various details of procedure are described.

Centrifugal spinning apparatus for artificial silk manufacture. W. S. MUMFORD. Brit. 338,958, Aug. 29, 1929. Structural features.

Piston pump for solutions of viscose, cellulose acetate, etc. TEXTILES ARTIFICIELS ING. A. MAURER. Ger. 518,100, June 22, 1929.

Spinning pumps for artificial silk. LOUIS CLAUDE BRUN. Fr. 37,287, July 30, 1929. Addn. to 658,463 (*C. A.* **23**, 5317).

Apparatus for dry-spinning of artificial silk filaments. NELSONS SILK, LTD., and J. NELSON. Brit. 338,881, July 25, 1929. Structural features.

Pulp from wood. LINN BRADLEY and EDWARD P. MCKEEFE (to Bradley-McKeefe Corp.). U. S. 1,795,754, March 10. Wood is digested in a cooking liquor contg. most of its soda in the form of a sulfite of Na; the residual liquor is subjected to a treatment including a reducing furnacing operation to yield a product contg. Na_2CO_3 and a relatively large amt. of Na_2S; and the Na_2S thus formed is utilized in an alk. cooking liquor to cook an addnl. quantity of wood. Residual liquor from this second cooking operation is subjected to a furnacing to yield a product contg. Na_2CO_3 and a lesser proportion of Na_2S than was present in the alk. cooking liquor, and the furnace product is subjected to a sulfiting to produce a cooking liquor contg. a quantity of Na_2SO_3 at least equiv. to any $Na_2S_2O_3$ present; and the cycle is repeated, by use of the last-mentioned cooking liquor in the first stage of the process. U. S. 1,795,755 relates to a cyclic process, in which one lot of wood is cooked in a liquor contg. SO_2 and $NaHSO_3$ and another lot of wood is cooked in a liquor contg. NaOH and a lesser quantity of Na_2S, residual liquors from these

2 operations being mixed and suspended matter sepd. This is followed by addn. of a Na compd. such as NaOH capable of redissolving remaining suspended org. material, concn., treatment of a portion of the concd. liquor by a reducing furnacing operation to form Na_2CO_3 and a considerable amt. of Na_2S, treatment of another portion of the liquor by furnacing to produce mainly Na_2CO_3 without much Na_2S, forming sep. liquors from these 2 furnace products, causticizing the liquor contg. the greater proportion of Na_2S to form a cooking liquor contg. NaOH and Na_2S, and subjecting the other liquor to treatment to form a cooking liquor contg. $NaHSO_3$ and SO_2 and not contg. any objectionable quantity of $Na_2S_2O_3$. U. S. 1,795,756 relates to a generally similar process in which, however, the wood cooked in alkali is treated with a larger proportion of Na_2S than NaOH when freshly charged into the digester. Cf. *C. A.* **25**, 816.

Pulp from material such as wood chips. Erwin H. Hussey (to Bauer Bros. Co.). U. S. 1,795,603, March 10. Material such as wood chips is disintegrated in the presence of sufficient water to thoroughly impregnate the material but without any substantial excess of water; further reduction and disintegration is effected (suitably by rotating disks) in the presence of a large quantity of water, followed by rolling, pressing and squeezing of the material, without appreciable cutting, between rotating, relatively movable disks having teeth inclined in an opposite direction to the direction of rotation. App. is described.

Bleaching wood pulp. Linn Bradley and Edward P. McKeefe (to Bradley-McKeefe Corp.). U. S. 1,795,757, March 10. Fibrous material from an incomplete digestion of wood is treated with liquor comprising a manganate such as $NaMnO_4$ together with an alkali metal hypochlorite. U. S. 1,795,758 describes numerous details and modifications of procedure of a process which may comprise digesting raw cellulosic materials in successive batches, one in an alk. cooking liquor and the other in an acid cooking liquor, and forming each liquor with inorg. compds. derived and recovered from the other liquor after the cooking operation therewith. Cf. *C. A.* **24**, 4634.

Paper pulp. Mead Pulp & Paper Co. Brit. 339,333, Aug. 28, 1929. In a continuous process of pulp production, stock of high consistency is treated with a gaseous chlorinating agent as it is fed down a tower (which may be fed with gaseous Cl from a liquid Cl supply). Numerous details of arrangement and construction of app. are described. Cf. *C. A.* **24**, 4392.

Paper pulp. Mead Pulp & Paper Co. Brit. 339,334, Aug. 28, 1929. For producing a free pulp of high strength, color, and clay-carrying quality suitable for paper making, from wood, straw, fibrous grasses and the like, such as that which has been subjected to an incomplete chem. digestion (*e. g.*, leached chestnut chips), the material is subjected to multi-stage and coördinated chlorinating treatment, the first stage being with an insufficient quantity of chlorinating agent acting at a limited temp. and the second stage involving treatment of a thickened pulp with a stronger chlorinating agent. Numerous details of app. and procedure and auxiliary and preliminary treatments of the material are described.

Rotating perforated drum apparatus for separating paper pulp, peat fiber, etc., from liquids. E. F. Sundström and K. E. Steen. Brit. 338,547, July 18, 1929. Structural features.

Treating black liquor from the soda-pulp process. Erik Häglund. Ger. 518,062, June 24, 1926. See Brit. 273,267 (*C. A.* **22**, 1854).

Tfeating black liquor formed in the soda-pulp process. Erik Häglund. U. S. 1,795,557, March 10. The liquor is subjected to a heat and pressure treatment to ppt. most of the org. substances present as carbonaceous and pitchy material. After sepn. of the liquor from the ppt. thus formed, it is causticized (the acetate content being left substantially unchanged) and concd., and a portion of the NaOAc content is crystd. out. Another portion of the causticized liquor is used to increase the alkalinity of the black liquor, and a further portion is used to act upon pulp-forming fibrous material; crystd. NaOAc and volatile products are recovered. An arrangement of app. is described. Cf. *C. A.* **21**, 3128; **24**, 4932.

Paper. Felix Thunert. Ger. 518,099, Dec. 24, 1924. A method is described of making packing, etc., paper having a downy upper surface, by securing cellulose wadding to a smooth paper support by means of an adhesive.

Paper, molded sheets, blocks, etc., from fibrous materials. Respats, Inc. Brit. 339,528, Jan. 11, 1930. See U. S. 1,770,430 (*C. A.* **24**, 4634).

Bituminous paper board. A. Sommer. Hung. 100,522, Aug. 7, 1929. Molten asphalt is emulsified with paper pulp by mixing and heating. The emulsion is broken down by drying, and paper board is made from the solid phase by rolling.

Roll for calendering apparatus. Theodor Gerth. U. S. 1,795,556, March 10. A

calendering roll comprises a core around which is wound a band or ribbon of material standing on edge and having its weft threads arranged in staggered relation.

Imparting high finish to paper. ALBERT L. CLAPP (to Bennett, Inc.). U. S. 1,797,048, March 17. After the drying operation, there is applied to paper an aq. dispersion of solid particles of waxes flexible at the calendering temp. of the usual hot calendering rolls at the dry end of the paper machine, and the paper is hot calendered. App. is described.

Apparatus (with twin glazing cylinders) for glazing paper. J. W. GRANT. Brit. 339,370, Sept. 13, 1929. Structural features.

Waterproof flexible paper. THE SCUTAN CO. Ger. 514,922, Nov. 25, 1927. See Brit. 281,316 (*C. A.* **22**, 3530).

24—EXPLOSIVES AND EXPLOSIVES

CHARLES E. MUNROE AND C. G. STORM

Fifty years' experimental research upon the influence of steam on combustion of carbonic oxide. WM. A. BONE. *J. Chem. Soc.* 1931, 338–61.—An historical account is given of expts. and theories on the combustion and explosion of gaseous mixts. from the time of H. B. Dixon's discovery of the activation by water vapor of the combustion of CO (1877) up to now. Chem. and phys. theories of gaseous explosions are considered in sep. sections. J. G. McNALLY

The laws of combustion of colloidal powders containing vaseline. H. MURAOUR AND G. AUNIS. *Compt. rend.* **192**, 418–21(1931); cf. *C. A.* **24**, 4396.—The variation in $\int p dt$, in which p is the pressure prevailing during combustion and t is time, was studied in powders contg. (1) vaseline and (2) centralite ($(EtPhN)_2CO$) to lower the temp. of explosion of the nitrocellulose-nitroglycerin mixt. The decrease in $\int p dt$ with d. of charge is much less with vaseline than with centralite. The powders contg. vaseline obey the same laws of combustion as other powders at high ds. of charge but not at ds. corresponding to pressures below 500 kg. per sq. cm. The peculiar behavior of vaseline is attributed to the fact that it is emulsified rather than dissolved in the powder. F. W. BROWNE

Dust explosions, with special reference to wood-working industries. H. R. BROWN. *Am. Soc. Mech. Eng.*, Advance paper, Dec. 1–5, 1930, 3 pp.—Explosions in flour mills have been common, but now this hazard is recognized in grain elevators, starch factories, sugar refineries, wood-working plants, textile mills and other factories in which materials in form of dust are manufd. Precautionary measures are suggested, and regulations have been tentatively adopted for prevention of dust explosions in wood-flour mfg. establishments. E. I. S

The constitution of atmospheres behind stoppings. T. DAVID JONES. *Colliery Guardian* **142**, 398–401, 493–4(1931).—Many analyses are reported of mine air contained in sections of coal mines which, for one reason or another, have been sealed off. Four different types are distinguished which are characteristic of the action taking place in the district sealed off. (1) The air is almost unchanged with time. There is little formation of CO_2. (2) The air is more or less rapidly replaced by CH_4, the CO_2 formed from the original air being pushed out. In one case CH_4 reached 90% in 12 weeks, the addnl. 10% being N. (3) The air is replaced by a mixt. of CO_2 and N_2 (black damp). In one unusual case black damp (with 18% CO_2) reached 100% in 134 weeks. This type is due to fires. When the O_2 has been reduced below 10% flames cannot exist, although heating may continue until the O_2 has been used up. (4) This results from a race between the accumulation of fire damp and the diminution of O. From a safety point of view explosions do not occur when the CH_4 exceeds 15% or the O_2 is less than 10%. Generally the CH_4 wins the race. Examples of consecutive analyses and diagrams illustrating the 4 types are given. A. L. KIBLER

Role of **gas masks in mines** (ESZTÓ) **13.** The propagation of flame in electric fields (GUÉNAULT, WHEELER) **2.** Use of HCl to prepare bore holes for blasting (Brit. pat. 338,454) **13.**

Explosive derived from hexamethylenetetramine. E. L. D'ASTECK. Brit. 339,024, Sept. 20, 1929. $(CH_2)_6N_4$ is oxidized with H_2O_2, the resulting product is treated with HNO_3 and is further oxidized with H_2O_2. Various details of procedure are described.

Blasting cap. WM. PRITCHARD, JR. (to Hercules Powder Co.). U. S. 1,795,440,

March 10. A weighting material such as Pb is placed in a cap comprising a casing and a charge which may be formed of fulminate-chlorate compn. in order to give the cap as an entirety a sp. gr. higher than that of coal, so that mech. sepn. from the broken coal is facilitated.

Diffusion apparatus for indicating the presence of combustible gases in air. BRUNO TREBITSCH. Austrian 120,986, Aug. 15, 1930.

Testing mixtures of coal dust and stone dust in mines. EMIL WITTE. Ger. 472,529, Dec. 11, 1925. The mixt. is compared with a graduated color tube contg. coal dust at one end and stone dust at the other, with gradual intermediate mixing.

Testing mixtures of coal dust and stone dust in mines, etc. EMIL WITTE. Ger. 514,162, June 15, 1929. Addn. to 472,529 (preceding abstr.).

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Biphenyl: A starting point in organic synthesis. GILBERT T. MORGAN AND LESLIE P. WALLS. *J. Soc. Chem. Ind.* 50, 94T(1931).—Biphenyl, now available industrially at a moderate price, is pointed out as a possible source of *intermediates for synthetic dyes and drugs*. Examples are given. H. W. LEAHY

The copperas indigo vat. J. CLAROU. *Tiba* 9, 247-51(1931).—A description of the vat dyeing of cotton with indigo in the presence of $FeSO_4$. A. PAPINEAU-COUTURE

Troublesome fibers in the dyeing of garments. VALETTE. *Tiba* 9, 141, 143 (1931).—A brief outline of the chem. and tinctorial properties of some fibers which give trouble to dyers and cleaners: acetate rayon, acetylated wool, "immunized" cotton, "passive" cotton, "amido" cotton. A. PAPINEAU-COUTURE

Cause of the greenish shade of cotton fabrics jigged in indigosol O by the steaming process. LOUIS A. DRIESSEN. *Tiba* 9, 139(1931).—One method of application of indigosol O consists in jigging cotton fabric in a bath contg. indigosol O, NH_4CNS, $NaClO_3$ and NH_4VO_3, drying and steaming 1-15 min. In some cases a greenish shade is produced. It is shown that this is due to the use of too much NH_4CNS which, on heating (especially if prolonged) gives rise to the formation of persulfocyanic acid. The trouble can be eliminated by reducing the proportion of NH_4CNS or by using NH_4 oxalate or lactate in place of NH_4CNS. A. PAPINEAU-COUTURE

Even dyeings on wool. ALB. BYTEBIER. *Rev. chim. ind.* 39, 262-5(1930). P. THOMASSET

Partial alkaline hydrolysis of acetyl silk as a pretreatment for dyeing. W. COLTOF, H. I. WATERMAN AND J. G. WOLF. *Z. angew. Chem.* 44, 163-8(1931).—Superficial hydrolysis of acetylcellulose fibers in dil. NaOH and AcOH, at 60°, attained max. effects, which depended on the alkali concn. The wt. losses were 4.2, 6.3 and 8.4% in 0.0067, 0.0101 and 0.0133 *N* NaOH. If complete deacetylation of cellulose units took place (as has been claimed), the cellulose formed should be calculable from the wt. losses. Extn. of the treated fibers with Me_2CO gave greater residues of cellulose than the calcd. values. It is concluded that intermediary layers of incompletely deacetylated material exist below the completely hydrolyzed surfaces. The treated fibers were dyed under standard conditions (1 hr. at 70°) with benzopurpurin 4B. Absorption was detd. by colorimetric examn. of the bath before and after dyeing. Absorption on the untreated fiber was negligible; it increased rapidly, at first, with increasing deacetylation, but reached a max. when the wt. losses were 2-3%. Greater absorption may be produced only by lengthening the time of dyeing. Consideration of this factor is of great importance to the dyer. K. H. ENGEL

Unit heaters prevent condensation in dye houses. J. R. COOPER. *Heating, Piping and Air Conditioning* 2, 767-9(1930).—A discussion of the problem of air transportation in plants where moisture removal is of paramount importance and a description of several specific installations of unit heaters in dye rooms. E. I. S.

Note on the boiling of cotton preliminary to bleaching. J. DUTREILLIS. *Tiba* 9, 245, 247(1931).—It is considered that the most logical procedure is as follows: treatment with hot 1.5°Bé. HCl, treatment with C_6H_6 or similar fat solvent and boiling at atm. pressure with Na_2CO_3; if necessary a pancreatin treatment can be carried out between the fat extn. and soda boiling. A. PAPINEAU-COUTURE

The use of liquid chlorine in the industry of bleaching cotton cloth. LA BLANCHISSERIE ET TEINTURERIE DE THAON-LES-VOSGES. (Sealed communication of 1914.) *Bull. soc. ind. Mulhouse* 97, 60-2(1931).—A process for the prepn. of hypochlorite liquors

and their use in bleaching cotton are described. The app. consists of a column in which an ascending stream of Cl gas meets a spray of NaOH soln. or milk of lime. I. H. O. BOXSER.

The generating and application of x-rays for textile investigations. HERMAN *Am. Dyestuff Reptr.* **20**, 163–6(1931).—Seven references are listed. A. K. JOHNSON

Physical and chemical properties of textiles. II. A. J. HALL. *Textile Mercury* **84**, 239(1931); cf. *C. A.* **25**, 2296.—Some effects of the phys. conditions of rayons and the methods of manuf. on the resistance of cellulose to snail enzyme degradation are shown. A. K. JOHNSON

Identification and analysis of rayons. H. TATU. *Russa* **6**, 175–87(1931).—A critical review of methods proposed for the identification and analysis of nitrocellulose rayon, the identification and analysis of acetate rayon, the sepn. of viscose from cuprammonium rayon, microscopical examn. and ultra-violet examn. Bibliography of 40 references. A. PAPINEAU-COUTURE

Pieces of artificial crepes containing acetate rayon. A. CRISPE. *Russa* **6**, 243–7 (1931).—Practical operating directions. A. PAPINEAU-COUTURE

Cellulose amyloid and the utilization of the amyloid effect in the textile industry. JUSTIN-MUELLER. *Tiba* **9**, 129–33(1931). The optimum conditions for the production of amyloid consist in dissolving 5.82 parts of cellulose in 100 parts of H_2SO_4 (d. 1.580) to a thick starch-like paste and then pouring the soln. slowly into a large vol. of cold H_2O, which gives a white, curdy ppt. To obtain a pulverulent ppt. it is necessary to use a large excess of acid, or to allow the latter to act for a longer period, but this results in attack of the amyloid with production of dextrin or glucose. On drying the ppt. after washing to neutrality, it becomes grayish, hard, horny and more or less translucent, but softens again on prolonged contact with cold water. The wet ppt. or its NaOH soln. does not reduce Fehling's soln.; but if allowed to stand after boiling with Fehling's soln. the surface becomes very slightly reddish, showing a very slight reduction by surface action. The chief characteristic is that the dried ppt. is more resistant to the action of reagents than the undried ppt., indicating that there is probably a certain amt. of polymerization on drying. The production of cambric effects on cotton by treatment with H_2SO_4 and the parchmentizing of paper are both considered to be due to a superficial amyloidation of the fabric or paper. Rapidly passing rayon (viscose, acetate, cuprammonium) fabrics through H_2SO_4 (50–52° Bé.), followed immediately by thorough washing and final treatment with dil. NH_4, increases the tensile strength, but gives a rougher touch. A. PAPINEAU-COUTURE

The behavior of the aqueous solution of domestic cocoons. I. II. HIDEO KANEKO. *J. Agr. Chem. Soc. Japan* **6**, 623–32, 1015–22(1930).—The greater the surface tension of the aq. soln. of boiled cocoons is, the better the reeling. The isoelec. pt. of aq. solns. in which the reeling is easy is 4.25–4.4. The sp. elec. cond. (k) of the aq. soln. $= \log C + B$, in which C is the concn. and B is the const. (about 1.1); k increases with the temp. The cond. of the soln. is changed more by acids than by bases. The cond. of a soln. having good reelability is not changed by the addn. of electrolytes. Y. KIHARA

Medulla in wool. A new test for detection of hairiness in the fleece. B. L. ELPHICK. *New Zealand J. Agr.* **42**, 91–8(1931).—Medullated fibers present a bright chalky appearance when a sample of wool, free of grease and dirt, is immersed in benzene and is viewed against a black background. Pure wool fibers have a silky transparent appearance. The test can be carried out in about 5 min. K. D. JACOB

Recovery of spinning oil from fulling plants. A. BEYER. *Tiba* **9**, 133–7(1931).—A brief outline of the advantages and of the various processes of recovery, and also of the necessity of controlling the compn. of the effluent to eliminate portions contg. such small amts. of oil as to render the recovery uneconomical. A. PAPINEAU-COUTURE

Glue and gelatin in the textile industry. HERMANN STADLINGER. *Kunstdünger u. Leim* **28**, 61–9(1931).—Numerous uses of these materials in various operations in mfg. textiles are described, with notes on the qualities required and suggestions for new uses. Many working formulas are included. C. J. SCHOLLENBERGER

Proteins of wool (SAITO) **11A.** Water requirements in the textile industry (KEHREN, STOMMEL) **14.** Aromatic amines [dyes] (Ger. pat. 515,758) **10.** Substitutes for sugars [in printing or dressing textiles] (Ger. pat. 518,196) **18.**

Deutscher Färberkalender, 1931. Wittenberg: A. Ziemsen Verlag. M. 5. Reviewed in *J. Soc. Dyers Colourists* **47**, 82; *Tiba* **9**, 211(1931).

Dyes. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 338,858, Dec. 20, 1928. An arylaminoanthraquinone contg. in the benzene ring to which is attached the arylamino group, a halogen atom in β-position, and in the other benzene residue a sulfonic acid group, is treated with sulfite (with or without the presence of phenol or a similarly acting compd.), which effects replacement of the β-halogen atom by a sulfo group. Examples are given of the production of water-sol. dyes suitable for wool dyeing and printing, giving fast blue to greenish blue shades.

Dyes. I. G. FARBENIND. A.-G. Brit. 338,747, Dec. 4, 1928. Halogenated dibenzopyrenequinones are made by causing halogen or a halogenating agent to react in an alkali-$AlCl_3$ melt with a 3,4,8,9-dibenzopyrene-5,10-quinone or a 4,5,8,9-dibenzo pyrene-3,10-quinone, or with a ketone capable of being transformed into such a pyrenequinone by ring closure. The products may be after-treated with a hypochlorite to improve the shades of the dyeings. Several examples are given, including dyes giving orange and scarlet tints.

Dyes. I. G. FARBENIND. A.-G. Brit. 339,489, Dec. 6, 1928. 4,5,8,9-Dibenzopyrene-3,10-quinones contg. both Cl and Br are made by chlorination of brominated dibenzopyrenequinones or by bromination of chlorinated dibenzopyrenequinones. Several examples are given for the production of dyes producing various red tints.

Dyes. I. G. FARBENIND. A.-G. Fr. 37,120, June 22, 1929. Addn. to 670,562. *N*-Dihydro-1,2,2′,1′-anthraquinoneazines contg. Me groups in the anthraquinone ring are made resistant to Cl by a treatment with H_2SO_4 and MnO_2 or other oxidizing agents having a similar action. An example is given of the treatment of the 3,3′-dimethyl deriv. Cf. *C. A.* **24**, 2608.

Dyes. I. G. FARBENIND. A.-G. Fr. 37,442, Sept. 18, 1929. Addn. to 667,108. The sulfonic acids of Fr. 667,108 (*C. A.* **24**, 1223) are replaced by the corresponding carboxylic acids of aromatic diamino compds. Examples are given.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 37,190, July 4, 1929. Addn. to 677,782 (*C. A.* **24**, 3378). Dyes of the general formula 2,3-$(R^1N{:}N)(HO_3S)C_{10}H_4$-$(NH.X.NH.R^2.N{:}NR^3)$-6, in which X represents a residue such as CO or CS or a triazine, quinazoline, pyridazine, pyrimidine or like heterocyclic residue, R^1 is the residue of anthranilic acid or a deriv. thereof, R^2 is an aryl ring and R^3 is an aryl ring contg. an OH and COOH group *o*- to one another, are prepd. by coupling the aminonaphthol derivs. with a diazo compd. corresponding to the group R^1. Examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 338,672, Oct. 10, 1928. Azo dyes (examples of which dye cotton yellow and red shades) are made by diazotizing the compds. produced by subjecting mono- or di-nitrobenzoylated diaminoarylsulfonic acids to slight reduction (such as is required to convert an aromatic nitro compd. into an azo- or azoxy-compd., as described in Brit. 313,636; *C. A.* **24**, 1227) and coupling with a coupling component. Several examples are given.

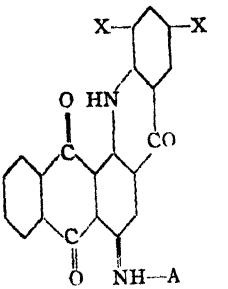
Azo dyes. I. G. FARBENIND. A.-G. Fr. 37,157, June 28, 1929. Addn. to 677,491 (*C. A.* **24**, 3116). Azo dyes are prepd. by coupling *o*-hydroxydiazo compds. with hydroxyquinolone derivs. and choosing the reaction components in such a manner that the product contains at least one sulfonic group. Thus, 4-chloro-2-aminophenol-6-sulfonic acid is diazotized and coupled with 1-phenyl-4-hydroxy-2-(1)quinolone to give a dye which dyes Cr-mordanted wool a Bordeaux-red shade. Other examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 37,203, July 10, 1929. Addn. to 674,638 (*C. A.* **24**, 2892). Azo dyes are prepd. in substance or on the fiber from condensation products of diazo compds. with primary amines which contain groups giving soly. in water. Thus the diazoamino compd. of 2,5-dichloro-1-aminobenzene and 4-sulfo-2-aminobenzoic acid is coupled with 2′,5′-dimethoxyanilide-2-hydroxynaphthalene-3-carboxylic acid, the dye formed giving a yellowish brown shade. Several examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 37,383, Aug. 31, 1929. Addn. to 645,771 (*C. A.* **23**, 2041). Azo dyes are prepd. by coupling 2,3-hydroxynaphthoyl-2-amino-3-naphthol ethers with diazo compds. of *p*-aminodiaryl ethers, the 2 and 5 positions of which, with respect to the NH_2 group, are substituted but which do not contain COOH, SO_3H or nitric groups, *e. g.*, 3-methyl-6-chloro-4-aminodiphenyl ether.

Metal compounds of azo dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 518,016, Sept. 8, 1928. See Brit. 297,478 (*C. A.* **23**, 2836).

Azo dyes containing chromium. FRITZ STRAUB and HERMANN SCHNEIDER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,796,058, March 10. A chromable dye such as that formed from diazotized 6-nitro-2-amino-1-phenol-4-sulfonic acid and β-naphthol is treated with Cr hydroxide in the presence of a water-sol. salt of hydrosulfuric acid such as Na_2S. Various other examples are given. Cf. *C. A.* **24**, 5164.



Chromium compounds of azo dyes. I. G. FARBENIND. A.-G. Brit. 338,595, Aug. 22, 1929. Compds. dyeing wool greenish yellow shades are formed by boiling a Cr salt with dyes such as those formed from 2-chloroaniline (or 4-chloro-3-toluidine) and the methylpyrazolone from 2-amino-2'-hydroxy-4-sulfo-3'-carboxy-5'-methyldiphenyl sulfone or similar components. Cf. *C. A.* 24, 1746.

Vat dyes. I. G. FARBENIND A.-G. Brit. 339,396, Sept. 28, 1929. An acylating agent is caused to react on a condensation product obtained by treating a 1-(*Bz*-1-benzanthronylamino)-4- or 5- or 8-aminoanthraquinone or a substitution product halogenated in the benzanthrone residue with an alkali condensing agent. Products are obtained dyeing olive shades fast to Cl, and several examples are given. Among the acylating agents which may be used are benzoyl chloride and cinnamic acid chloride.

Vat dyes. BRITISH DYESTUFFS CORP., LTD., and ANTHONY J. HAILWOOD. Fr. 37,360, Aug. 22, 1929. Addn. to 638,387 (*C. A.* 23, 286). The dye obtained by the fusion of naphthalimide or acenaphthenequinone with NaOH under conditions other than those indicated in the 1st example of Brit. 26,690/13 is brought into a sol. or colloidal form for use in the vat by treatment with an acid agent such as oleum or $ClHSO_3$ followed by a fresh pptn. by dilu.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 37,173, July 2, 1929. Addn. to 669,740 (*C. A.* 24, 1990). The action of Br on dibenzanthrone or isodibenzanthrone or their derivs. for the production of dyes is carried out in the presence of $ClHSO_3$ at temps. below 50°.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 37,184, July 2, 1929. Addn. to 674,639 (*C. A.* 24, 2891). Vat dyes are prepd. by the reaction of a halogenated anthraquinone-acridone contg. 3 or more halogen atoms with a halogenated aromatic amine. The products obtained probably correspond with the formula

in which X represents any halogen atoms and A is an aromatic ring. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 37,309, Aug. 6, 1929. Addn. to 679,912 (*C. A.* 24, 3909). Vat dyes are prepd. by condensing an α-hydroxyanthracene with an α-compd. of a 4-methyl-5-halo-7-alkoxyisatin. Thus, α-anthrol heated in PhCl with 4-methyl-5-chloro-7-methoxyisatin gives 2-anthracene-4'-methyl-5'-chloro-7'-methoxy-2'-indole indigo which dyes fiber a greenish blue shade.

Vat dyes. I. G. FARBENIND. A.-G. (Wilhelm Eckert and Otto Braunsdorf, inventors). Ger. 517,195, June 19, 1928. See Brit. 313,887 (*C. A.* 24, 1226).

Vat dyes. I. G. FARBENIND. A.-G. (Hugo Wolff and Ernst Honold, inventors). Ger. 517,442, Apr. 30, 1929. Addn. to 489,957 (*C. A.* 24, 2305). Vat dyes are obtained by treating polyanthraquinonylaminobenzanthrone compds. which have an anthraquinonylamino residue in the *Bz*-1-position, with alkali and, optionally, treating the resulting dye with acid condensing agents. Thus, di(1'-anthraquinonyl)-6-*Bz*-1-diaminobenzanthrone (obtained from 6-*Bz*-1-dihalobenzanthrone and 1-aminoanthraquinone) is fused with NaOH and alc. at 180–200°. The resulting mass is heated with water, filtered and washed. The dye so obtained colors vegetable fibers in olive-brown shades from a NaOH and hydrosulfite vat. Further examples are given. Cf. *C. A.* 24, 4941.

Vat dyes. I. G. FARBENIND. A.-G. (Georg Rösch, inventor). Ger. 518,017, Aug. 9, 1929. Yellow to orange vat dyes are prepd. by combining 2 mols. of an α-aminoanthraquinone with 1 mol. of naphthalene-2,6-dicarboxylic acid or its derivs. not contg. OH groups. Suitably, the dichloride of the acid is heated with the α-aminoanthraquinone in $PhNO_2$. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Heinrich Neresheimer and Wilhelm Schneider, inventors). Ger. 518,230, July 26, 1929. The dyes described in Ger. 491,430 (*C. A.* **24**, 2306) are halogenated. The products are faster to Cl than the initial dyes and give modified dyeings. Examples are given.

Violet vat dyes. I. G. FARBENIND. A.-G. (Maximilian P. Schmidt and Wilhelm Neugebauer, inventors). Ger. 502,352, Apr. 30, 1927. Haloperylenetetracarboxylic acids contg. not more than 3 halogen atoms are condensed with *o*-diamines. An example is given.

Blue-green vat dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 339,516, Dec. 24, 1929. 2-Methylbenzanthrone or a deriv. contg. a replaceable substituent in the *Bz*-1-position is sulfurized and converted into products of improved properties by dissolving in H_2SO_4 and dilg. the soln. thus formed continuously with water or with aq. H_2SO_4 so that the dye is pptd. but impurities are retained in soln., or purification may be effected by reducing to the leuco compd., sepg. and oxidizing the latter if desired.

Blue vat indanthrone dye. D. A. W. FAIRWEATHER, J. THOMAS and SCOTTISH DYES, LTD. Brit. 338,891, May 25, 1929. 2-Aminoanthrahydroquinone-9,10-disulfuric ester is oxidized by use of a cupric salt such as the sulfate or chloride (suitably with addn. of NaOH or HCl), to avoid danger of over-oxidation and produce a product which is presumably indanthrone.

Acid wool dyes. I. G. FARBENIND. A.-G. (Rudolf Müller and Ernst Honold, inventors). Ger. 518,229, Mar. 18, 1928. The diazo compds. from 1-aminoanthraquinone-2 sulfonic acids substituted in the 4-position with a readily exchangeable atom or group or the residue of a base are treated with primary or secondary bases. Thus, the diazo compd. from 1-amino-4-bromoanthraquinone-2-sulfonic acid may be treated with $PhNH_2$ while cooling in the presence of a little Cu. The reaction proceeds with evolution of N. Other examples are given also. Cf. *C. A.* **25**, 214.

Acid wool dyes. WILHELM ECKERT (to General Aniline Works). U. S. 1,796,011, March 10. Dyes producing generally yellow or greenish yellow dyeings (according to the several examples described) on animal fibers or cellulose esters and ethers are produced by causing a compd. of the group consisting of NH_3, alkyl NH_2, aralkyl—NH_2, aryl—NH_2 and *o*-arylene-$(NH_2)_2$ (the aryl residues being substituted or not) to act upon a compd. of the general formula of a naphthalic anhydride wherein may be substituted the sulfonic or the sulfamic acid group and a univalent substituent in the presence of water at a temp. of about 100°. The use of the Na deriv. of 4-sulfamino-1,8-naphthalic anhydride and *o*-$C_6H_4(NH_2)_2$ and similar starting materials is described, and the same or similar dyes are obtained by transforming the reaction products of naphthalic anhydride, or a deriv. thereof, with NH_3, an aliphatic or aromatic amine into the sulfonic acids or sulfamic acids, resp., or by subjecting naphthalic anhydride or a deriv. thereof to react with a sulfonic acid of an amine. U. S. 1,796,012 describes the production of generally similar dyes by treating nitronaphthalic acid derivs. (such as nitro-1,8-naphthalimide contg. H, alkyl, aralkyl or aryl on the N) in an aq. soln. with such reducing agents as simultaneously effect the entrance of a sulfonic acid group. Such agents are, for instance hyposulfite, bisulfite or the like. It is advantageous to add to the aq. soln. a water-sol. org. solvent, *i. e.*, alc. The reaction is generally carried out at boiling temp., but it is also sufficient to heat the soln. to a somewhat lower temp. It is also possible to use as parent materials such nitronaphthalic acid derivs. as contain a sulfonic acid group. In this case the introduction of a further sulfonic acid group is unnecessary and it is sufficient to reduce the nitro group. Examples are given of the use as starting materials of *N*-methyl-4-nitronaphthalimide (or the corresponding ethylimide or phenylimide), 4-nitronaphthalimide and *N*-(*p*-sulfophenyl)-4-nitro 1,8-naphthalimide. Cf. *C. A.* **25**, 1097

Anthraquinone dyes. I. G. FARBENIND. A.-G. Brit. 339,266, Sept. 3, 1929. 1-Amino-4-bromoanthraquinone-2-sulfonic acid is caused to react with an aromatic amine contg. a hydroxyl group, which is etherified by a polyhydric alc., such as *o*- or *p*-aminophenol glycol ether or *p*-aminophenol glycerol ether, suitably in the presence of Cu or a Cu salt and of Na_2CO_3. The dyes dye wool clear blue or greenish blue shades.

Acylaminoanthraquinone dyes. I. G. FARBENIND. A.-G. Brit. 339,267, Sept. 3, 1929. Two mol. proportions of α-aminoanthraquinone or a substitution product are condensed with 1 mol. proportion of a reactive deriv. of a naphthalenedicarboxylic acid, a diphenylmethanedicarboxylic acid, diphenyl-*p*,*p*'-dicarboxylic acid or a halogen substitution product of such compds. (with the exception of such dicarboxylic acids as are capable of forming internal anhydrides). Various examples are given for the production of dyes giving yellow, orange and red shades.

Dibenzanthrone dyes. R. S. BARNES, R. F. THOMSON, J. THOMAS and SCOTTISH

DYES, LTD. Brit. 339,324, May 31, 1929. Enolic esters of dibenzanthrone or halogenated dibenzanthrone are treated with oxidizing agents (such as $Na_2Cr_2O_7$, $K_2S_2O_8$, $KMnO_4$, V_2O_5 or H_2O_2) in the presence of an inorg. acid of at least 4% strength. Various details and examples are given.

Sulfurized dyes. I. G. FARBENIND. A.-G. Fr. 37,484, Oct. 2, 1929. Addn. to 653,785 (*C. A.* **23**, 3816). Sulfurized dyes are prepd. by heating halogenated dinaphthylene dioxide with S, with or without diluents of high b. p., or melting these compds. with polysulfides in the known manner. Examples are given of dyes from the tetrachloro, pentachloro, tetrabromo and hexachloro compds. Cf. *C. A.* **25**, 1096.

Sulfuretted dyes. I. G. FARBENIND. A.-G. Brit. 339,410, Oct. 10, 1928. Acid mordant dyes probably of the thiazine series are obtained by reaction of S in fuming H_2SO_4 on a β-hydroxynaphthoquinonesulfoarylimide (in which O, OH and the $NRSO_2H$ group are in the 1, 2 and 4 positions, resp.) in which the aryl group (R) may contain further substituents with the exception of alkylamino groups. Examples are given for the production of dyes dyeing wool from an acid bath reddish violet shades which turn green when after-chromed; the dyes are suitable for printing wool or cotton by the chrome printing process. Cf. *C. A.* **25**, 2005.

Pastes from insoluble mordant dyes. E. YA. VINETZKAYA. Russ. appl. 22,888, Sept. 13, 1927. Pastes are prepd. from alizarin by mixing the dry dye with 5–10% of a protective colloid, such as gum tragacanth, etc., and grinding the mixt. in a colloid mill together with water.

Pasting sulfur dyes with resin soaps. I. G. FARBENIND. A.-G. (Franz Schweitzer-Hennig and Walter Hagge, inventors). Ger. 518,198, June 10, 1928.

Improving the solubility of dyes. ARTHUR R. MURPHY and JOSEPH B. OESCH (to Newport Chemical Corp.). U. S. 1,796,115, March 10. A dye such as direct fast yellow 5G is dissolved in water in the presence of a sol. pyrophosphate salt such as Na pyrophosphate, which serves as a solubilizing agent.

Fuchsin. C. N. IGNATYEV and I. I. VASIN. Russ. appl. 50,998, July 11, 1929. Fuchsin is prepd. by heating above 100° in the presence of air a mixt. of aniline, *o*- and *p*-toluidine and activated carbon without the addn. of any kind of oxidizer. The fuchsin is extd. from the melt by any of the known methods.

Parafuchsin. S. N. IGNATYEV and I. I. VASIN. Russ. appl. 59,307, Nov. 29, 1929. Parafuchsin is prepd. by heating a mixt. of $(p\text{-}H_2NC_6H_4)_2CH_2$, aniline and its salt, iron chloride and activated wood charcoal in the presence of air. The dye formed is extd. from the melt, which is first freed from the excess of aniline by the usual methods. The extn. can be carried out, *e. g.*, first with acidified water and then with org. solvents.

Bisulfite compound of alizarin blue. A. A. RAZUMEVEV. Russ. appl. 49,462, June 19, 1929. A mixt. of alizarin blue paste or the dry dye with a soln. of alkali is super satd. with sulfurous gas under agitation and let stand under ordinary or superatmospheric pressure at ordinary or elevated temp. until a sample is completely sol. in water. The product is then isolated by ordinary methods.

Anthanthrone derivatives. I. G. FARBENIND. A.-G. (Max A. Kunz, Karl Köberle and Erich Berthold, inventors). Ger. 518,231, Aug. 10, 1928. New compds. useful as *vat dyes* or *intermediates* are prepd. from di- or poly-aminoanthanthrones by substituting a radicle for H in one or more of the NH_2 groups. Examples are given describing the reaction of diaminoanthanthrone with PhCOCl, 1-chloroanthraquinone and 1-aminoanthraquinone-2-carboxylic acid chloride. Cf. *C. A.* **25**, 602.

Condensation products from benzoin. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 517,498, July 20, 1928; Fr. 37,391, Sept. 5, 1929. New compds. are prepd. by treating benzoin with aromatic sulfonic or carboxylic acids in the presence of a condensing agent, *e. g.*, H_2SO_4, oleum, or HSO_3Cl. Thus, a soln. of Na benzenesulfonate in H_2SO_4 may be stirred with benzoin at 80–90° until a sample gives a clear soln. in water. Alternatively, mixts. of benzoin and aromatic compds. may be treated with reagents having both a sulfonating and condensing action. Thus, $C_{10}H_8$ and benzoin may be fused together and the cooled melt introduced into H_2SO_4 and HSO_3Cl at 60°. Other examples are given also. The products are useful as assistants in the *manuf. of lakes and dye pastes* and in dyeing with ice colors and vat dyes.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 338,764, Dec. 16, 1929. 2-Aroylbenzanthrones are made by treating benzanthrones contg. the group $—CH(R)CN$ (in which R represents aryl) in the 2-position, described in Brit. 319,593 (*C. A.* **24**, 2613), with oxidizing agents such as $KMnO_4$ or $Na_2Cr_2O_7$ in the presence of org. diluents such as glacial HOAc or acetone. Several examples are given.

Dye intermediates. I. G. FARBENIND. A.-G. (Walter Mieg, Berthold Stein and

Willy Trautner, inventors). Ger. 518,213, May 3, 1927. New condensation products are prepd. by treating aminoanthraquinones or their derivs. or substitution products with alc. alkali hydroxide solns. at a temp. below 100°, while leading air into the reaction mixt. The products are strongly colored and are sol. in H_2SO_4, but they are not useful as vat dyes. Examples are given.

Gray dyeings on furs, hairs and feathers. I. G. FARBENIND. A.-G. Brit. 339,444, Nov. 7, 1928. The material (with or without mordanting) is treated with a soln. contg. a suitable oxidizing agent such as H_2O_2 and a 4-amino-*N*-alkyl- or *N*-aralkyldiphenylamine or a 4′-halo- or 4′-alkyl- deriv. Various examples and details of procedure are given.

Color lakes. WILHELM EBERLEIN. Ger. 515,981, Jan. 25, 1928. Color lakes are produced by pptg. basic dyes by sulfite-cellulose lye. Fixing agents, emulsions, fats and waxes may be added. Thus methyl violet is treated with the lye. $Al(OH)_3$ may be added to form a printing paste. Addn. of a colloid (*e. g.*, bentonite) and wax or oil renders the lake suitable for use as a marbled paper-coloring agent.

Dyeing textile materials. PIETER MIJER (to Two-Tone Corp.). U. S. 1,796,039, March 10. Various details of app. and procedure are described for coloring webs of permeable fabric by forming 2 color clouds while sepg. the heavy particles or drops from the lighter particles and exposing one face of the fabric to one of the clouds and the other face to the other cloud. Cf. *C. A.* **24**, 3383–4.

Dyeing piece goods and yarns with vat dyes. I. G. FARBENIND. A.-G. (Gerhard Poetzsch and Hermann Jäger, inventors). Ger. 518,197, Feb. 3, 1928. Better penetration is obtained by slop-padding the materials with the unvatted dye paste with the addn. of an agent promoting running or bleeding, and then treating the materials as usual with an alk. hyposulfite soln. Suitable agents for promoting running are emulsions of oils and fats or their free acids or water-sol. derivs., *e. g.*, Turkey-red oil or cellulose derivs. forming neutral or alk. aq. colloidal solns., *e. g.*, an alkali salt of carboxymethyl cellulose. The method is intended particularly for tightly beaten cotton or linen fabrics or strongly twisted or mercerized yarns. Examples are given.

Dyeing fulled goods. V. V. KUVICHINSKII and N. V. VORONKOV. Russ. appl 41,382, Feb. 22, 1929. Fulled goods are steamed, known dye solns. are added by the usual methods and the goods are again steamed.

Dyeing acetyl cellulose. WOLFGANG JAECK and JOSEPH LANG (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,796,028, March 10. Acetylcellulose is treated with a colloidal prepn. from an intermixture of insol. aminoazo dyes having an affinity for acetylcellulose, with waste sulfite liquor, which serves as a dispersing agent. U. S. 1,796,029 relates to the similar use of aminoanthraquinones with waste sulfite liquor.

Dyeing cellulose esters. BRITISH CELANESE, LTD. Brit. 339,429, Oct. 26, 1928. In dyeing fabrics, such as those comprising cellulose acetate, formate, propionate or butyrate on machines of the winch type, formation of creases is avoided by partially saponifying the ester before dyeing, and delustering may be simultaneously effected. Various details of procedure and reagents used are given.

Dyeing fur, hair and feathers. I. G. FARBENIND. A.-G. (Karl Marx and Karl Bittner, inventors). Ger. 518,199, Dec. 11, 1928. The mordanted or unmordanted materials are treated with an oxidizing agent and a base (or its salt) of the formula $R_3R_2NC_6H_4NR_1CH_2CH_2N(alkyl)_2$, where R_1 is H or an alkyl group and R_2 and R_3 are H or alkyl or aryl groups. Nuclear substitution products of such bases may also be used. Thus, Cu- or Fe-mordanted fur may be treated with an aq. bath contg. H_2O_2 and 4-amino-1-(ω-diethylaminoethylamino)benzene, brown shades being obtained. Other examples are given also. Cf. *C. A.* **25**, 2007.

Printing with vat dyes. I. G. FARBENIND. A.-G. Fr. 37,188, July 3, 1929. See Brit. 314,904 (*C. A.* **24**, 1522).

Printing with vat dyes. I. G. FARBENIND. A.-G. Fr. 37,282, July 4, 1929. Addn. to 642,991 (*C. A.* **23**, 1514). Merchandise is printed with a vat dye mixed with thickening agents other than cellulose esters or ethers capable of easy pptn., and the merchandise is treated with a reducing agent and an alkali. Examples are given of the use of carrageen moss.

Printing fabrics. I. G. FARBENIND. A.-G. (Ludwig Löchner, inventor). Ger. 516,088, Sept. 12, 1928. Addn. to Ger. 513,526 (*C. A.* **25**, 2006). In producing polychromatic effects by ester salts of vat dyes by the method of 513,526, β-naphthol and other coupling compds. are used instead of 2,3-hydroxynaphthoic acid arylides. Thus, fabric is soaked in a lye contg. β-naphthol, Turkey-red oil and NaOH. For red printing, the dried fabric is treated with a paste contg. diazotized *p*-nitroaniline, water, starch and AcONa. Further examples are given.

Printing wool. I. G. FARBENIND. A.-G. Fr. 37,474, Sept. 30, 1929. Addn. to 662,205 (*C. A.* **24**, 510). Illumination effects are obtained by printing wool, colored with a dye capable of being discharged, with discharge agents contg. esterified salts of leuco compds. of vat dyes, then treating the merchandise after steaming with a soln. of a persulfate contg. a free acid. Cf. *C. A.* **25**, 1102.

Piece-dyeing machine. SIEMENS-SCHUCKERTWERKE A.-G. (Georg Schlenk, inventor). Ger. 515,926, June 10, 1929. Addn. to 459,546.

Apparatus for washing, dyeing or other treatments of articles with liquids. KENNETH C. ANDERSON. U. S. 1,796,312, March 17. Structural features of an app. suitable for treating fabrics or other materials.

Treating textiles. CAMILLE DREYFUS. Fr. 37,382, Aug. 31, 1929. Addn. to 679,429 (*C. A.* **24**, 3911). A limited amt. of a sapong. agent in other than paste form is applied to textile materials of or contg. cellulose esters and rapidly dried.

Cleaning textiles, etc. LOUIS A. H. LANTELME. Fr. 695,131, May 6, 1930. A colloidal product such as starch, paste, bone glue or skin glue is used in the cleaning, washing, bleaching, dyeing or charging of textiles or threads of all kinds.

Waterproofing textile materials. FRITZ FUCHS. Austrian 121,364, Sept. 15, 1930. Addn. to 109,167 (*C. A.* **22**, 4836). The materials are impregnated with a soln of degradation products of vulcanized rubber in a high-boiling solvent, *e. g.*, pitch, asphalt or bitumen, with or without a drying oil. The prepn. of the soln. may be interrupted before soln. is complete, the undissolved portion acting as a filler.

Treating textile materials for mercerization. EMIL GRIMDER. U. S. 1,796,598, March 17. Woven material is subjected to the action of a shrinking liquid such as mercerizing soln. and is afterward subjected to a series of alternate cooling and transverse stretching treatments.

Bleaching and mercerizing machines. ALLGEMEINE ELEKTRIZITÄTS-GES. Ger. 515,613, Aug. 14, 1928. Details of regulating.

Bleaching bast fibers. I. G. FARBENIND. A.-G. Brit. 339,550, March 16, 1929. Bast fibers, either as crude fiber or in yarn or finished goods, are bleached by successive use of baths comprising: (1) peroxide, (2) acid Cl soln., (3) Na_2CO_3 soln., (4) alk. or neutral Cl soln. and (5) peroxide. Various details are described.

Bucking process for vegetable fibrous materials. GUSTAV ULLMANN Austrian 121,528, Oct. 15, 1930. See U. S. 1,787,880 (*C. A.* **25**, 828).

Bucking linen, etc. WERNER ERB. Ger. 515,675, May 10, 1927. Vegetable fibers are bucked in a mechanically stirred bleaching bath at 60–70°.

Preparing vegetable textile fibers for spinning. JOSEPH VIALLET (to N. T. Artificial Wool Co., Ltd.). U. S. 1,795,414, March 10 Cleaned waste vegetable fibrous material such as waste jute fabric is treated with a soln. which promotes fermentation such as a dil. soln. of $MgSO_4$, KNO_3 and K phosphate and heated to 30° with a softening agent such as olein, and after the fermentation has sufficiently proceeded the material is unravelled and boiled with a dil. alkali soln.

Textile fiber from materials such as ramie, flax, hemp, sisel and bamboo. DINSHAW R. NANJI (one-half to Duncan M. Stewart). U. S. 1,796,718, March 17. The material is heated with a 0.1–0.5% $(NH_4)_2SO_4$ soln. at a temp corresponding to a vapor pressure of 1–2 atm. for 60–20 min. and then subjected to pressure to remove slimy matter; subsequently the fiber is washed, dried and obtained from the straw by an ordinary scutching or similar process. U. S 1,796,719 describes a process for the manuf. of textile yarns consisting in resolving natural bast fibers such as those of plants of the genus *Boehmeria* embodying ultimate filaments of a length of at least 2.5 in. into such ultimate fibers, blending the latter with synthetically produced fibers such as any variety of rayon and then spinning the blend. Cf. *C. A.* **24**, 1750

Fiber and yarn from unretted flax. HENRY C. WATSON and MARTIN WADDELL (to Watson-Waddell Ltd.). U. S. 1,795,528, March 10 After breaking, scutching and twisting the fibers into a rove, the rove is wound onto an open reel in the roving frame, retted while on the reel, washed and spun. U. S. 1,795,529 and U. S. 1,795,530 also relate to app. for treating flax.

Dressing yarns. EDOUARD PINEL. Ger. 518,195, Nov. 27, 1926. Yarns of cotton, wool, etc., are treated with a soln. of carob-bean gum, which may contain a softening agent such as glycerol, and then with a soln. of starch or other size.

Singeing fabrics. W. OSTHOFF. Brit. 339,281, Aug. 28, 1929. A rich excess of O is supplied with the primary air or O to a gas or vapor burner and singeing is effected by the highly heated O thus obtained. App. is described. Cf. *C. A.* **24**, 511.

Delustering fibers of fabrics of regenerated cellulose. I. G. FARBENIND. A.-G. (Walther Schieber, Hugo Pfannenstiel and Herbert Mahn, inventors). Ger. 518,194,

Aug. 22, 1929. The materials are treated with a soln. of a cellulose ester or ether in conjunction with a non-solvent for the ester or ether, with the result that a cloudy film is produced on the materials when they are dried. Thus, regenerated cellulose yarn may be treated with a 0.2% soln. of benzylethylcellulose in equal parts of MeOH and C_6H_6 to which 10% of water has been added. Alternatively, the yarn may be impregnated with a simple soln. of the cellulose deriv., and the non-solvent applied later, *e. g.*, by steaming.

Carbonizing cellulosic fibers in mixed goods. H. DREYFUS. Brit. 339,300, Aug. 2, 1929. Mixed fabrics contg. cellulosic fibers such as cotton together with other materials such as cellulose derivs., wool and silk are heated in inorg. acid or acid salt solns. sufficiently dild. to have no deleterious effect on the non-cellulosic materials, to render the cellulose fibers removable without drying in the presence of a carbonizing reagent. Ornamental effects may be produced by use of colored or other reserves, and delustering of cellulose acetate may be prevented by avoiding undue heating or by using suitable protective reagents.

Filling and weighting fabrics of cellulosic materials. R. W. R. MACKENZIE, E. H. ROBINSON, D. LUMSDEN and M. FORT. Brit. 338,654, Sept. 23, 1929. Materials such as cotton or linen are loaded and filled "in an invisible way" with mineral loading agents such as clay, talc or barite (alone or together with unwoven cotton, wood fiber, paper or paper pulp) by rendering them sticky by treatment with a plasticizing agent such as H_2SO_4, caustic alkali, CS_2, cuprammonium soln. or the like, applying the filling before, during or after the plasticizing treatment, and subsequently subjecting the material to a setting bath. The properties of the material are stated to be improved in various respects.

Artificial silk, etc. I. G. FARBENIND. A.-G. Brit. 339,089, Nov. 14, 1928. Artificial threads, hairs, bands, etc., are made by dissolving natural silk waste in H_3PO_4, coagulating the viscous soln. thus formed by use of an alkali metal salt soln. (suitably a NaCl soln. contg. also NH_4 formate) and stretching the coagulated material to the desired form. Various details of the process are described.

Artificial silk, etc. H. DREYFUS. Brit. 338,989, May 31, 1929. Filaments, threads, ribbons, films, etc., of cellulose or its derivs. such as nitrocellulose are subjected to the action of sulfonic acids contg. at least 6C atoms (such as benzenesulfonic acid) of a concn. of at least 20% (preferably 30–50%) for the purpose of improving the strength and elasticity and modifying the luster of the material. The process is particularly suitable for the treatment of viscose products made from alkali cellulose unripened or ripened for only a short time. After treatment, the sulfonic acids are preferably removed by washing with water alone or with water contg. an alkali or base. As a substitute for or addn. to the sulfonic acids, acids such as methylphosphinic acid or nitrophenylphosphinic acid may be used, and benzylsulfonic acid, phenolsulfonic and-disulfonic acids and naphthalene- and naphtholsulfonic acids may be used. Various details and modifications of procedure are described.

Dull finish viscose silk. BENNO BORZYKOWSKI (to Swiss Borvisk Co.). U. S. 1,796,744, March 17. The viscose silk, while still contg. S, is treated directly with a bleaching agent such as a very dil. Cl soln. which will not remove the S.

Treating raw silk. I. G. FARBENIND. A.-G. (Robert Griessbach and Otto Ambros, inventors). Ger. 513,373, Jan. 22, 1928. Raw silk is scoured by treatment with a soln. contg. an activated protease, *e. g.*, papain activated with a trace of HCN. Examples are given.

Impregnating jute bags or other fabrics. L. D'ANTAL. Brit. 338,538, Oct. 19, 1928. An impregnating material is prepd. by oxidizing a vegetable drying oil (such as linseed oil or sunflower oil) or a mixt. of such oils by treating at temps. of 180–200° or higher with acid sludge from oil refining. Various details of treatment are described and mention also is made of the use of castor oil and substances contg. the SO_4 radical.

Apparatus for carbonizing woollen fabrics in open width. ERNST GESSNER A.-G. Ger. 518,310, May 6, 1928.

Gas-cell fabric for aircraft lighter than air. ARTHUR D. CUMMINGS (to Goodyear Tire & Rubber Co.). U. S. 1,797,189, March 17. A textile material is impregnated with waterproofing material such as Al acetate, oleate or stearate and provided with a coating of an agglutinant such as glue or gelatin and with a ply of material, such as goldbeater's skin or "cellophane," which is highly impermeable to inflating gases, over the agglutinant.

Nitrocellulose and linoxyn mixture suitable for coating fabrics, etc. VICTOR SCHOLZ (one-half to Atlas Ago Chemische Fabrik A.-G.). U. S. 1,796,219, March 10. Linseed oil is oxidized and polymerized in the presence of a Pb compd. catalyst such as

PbO or Pb linoleate and kneaded, the kneaded oil is dissolved in alc. with use of heat and pressure, and the resulting soln. is mixed with nitrocellulose. Cf. *C. A.* **25**, 2313.

Mothproofing fabrics. The Larvex Corp. Ger. 515,632, Nov. 11, 1928. See Brit. 301,421 (*C. A.* **23**, 4085).

Mothproofing wares. I. G. Farbenind. A.-G. (Wilhelm Lommel and Henrich Münzel, inventors). Ger. 515,956, Jan. 1, 1930. The wares are rendered mothproof by treatment with Sr salts, *e. g.*, $Sr(NO_3)_2$.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Aluminum powder for paints. Brit. Eng. Standards Assoc., *Specification* No. **388**, 6 pp.(Aug., 1930). Specifications. E. I. S.

Measurement of color tone. W. van Wüllen-Scholten. *Farben-Ztg.* **35**, 1824–5 (1930).—After a brief discussion of the Ostwald and the Baumann-Prase systems of color designation, the author recommends the step-photometer. It should be useful in standardizing tinting pigments. G. G. Sward

Luminescence analysis. II. Luminescence of white painters' colors and the employment of luminescence analysis for investigations of paintings. Ernst Beutel and Artur Kutzelnigg. *Monatsh.* **57**, 9–14(1931); cf. *C. A.* **24**, 2952.—The work was undertaken from the point of investigation of paintings to det. their origin. Most ZnO whites showed canary yellow, one only showing brown. This was so strong in even min. quantities that quant. ests. were impossible. $PbCO_3$ showed a *beige* color and could be identified in mixts. with $BaSO_4$. TiO_2 showed dark violet and mixts. with ZnO showed gradations up to the ZnO yellow. In com. colors the vehicle had little influence on the luminescence. The presence of ZnO could be established with certainty, but $PbCO_3$ not so surely, partially on account of the variety of reactions possible after exposure to air for long periods. It varies greatly as the paintings yellow with age. Gregg M. Evans

Difficulties in paint and varnish manufacture. Robert Bürstenbinder. *Farbe u. Lack* **1931**, 135.—Many difficulties attributed to faulty material are often due to improper formulation or to carelessness. A careful study by producer and user will eliminate misunderstandings and uncover economies. Some specific examples are given. G. G. Sward

Preparation and investigation of titanium white. Paul Askenasy and Kurt Heise. *Z. anorg. allgem. Chem.* **196**, 257–83(1931).—A completely Fe-free metatitanic acid can be obtained from a Ti sulfate soln. contg. Fe by sepn. as Ti K oxalate followed by hydrolysis of the mixed oxalate. This takes place at 135°, the yield depending upon the diln. Orthotitanic acid can be sepd. quantitatively in the cold at a p_H of 4. At this acid concn. $FeSO_4$ remains in soln. By resoln. of orthotitanic acid in H_2SO_4 and hydrolytic sepn. of metatitanic acid at 95°, a completely Fe-free high-grade paint pigment is obtained. The brilliancy of this Fe-free TiO_2 is comparable with that of other white pigments, while its covering power is not approached by any other. The influence of the ratio $TiO_2/BaSO_4$ upon covering power was studied. Pigments which were obtained by pptn. of the metatitanic acid upon a $BaSO_4$ suspension were superior in covering power to the corresponding mech. mixt. of TiO_2 and $BaSO_4$. The best covering power was obtained when the $BaSO_4$ and metatitanic acid were simultaneously pptd. In the extn. of Ti from ilmenite with H_2SO_4, 6 hrs.' treatment with a 55% acid is sufficient. This produces a basic sulfate metatitanic acid mixt. contg. Fe. Removal of Fe by treatment with acids leads to too great a loss of Ti. H. Stoertz

Standoil. R. Priester. *Verfkronick* **3**, No. 10, 12–8(1930); *Chimie & industrie* **25**, 418(1931).—Prolonged heating of linseed oil (and others) at 280–300° produces an increase in the viscosity and the acidity, which occurs more rapidly the higher the temp. The effect of temp. was studied on 10-kg. samples in Al kettles at 280°, 285°, 290°, 295° and 300°. The viscosity increases as an exponential function of the time of heating. The acidity increases fairly rapidly at first (1st hr.), and then approx. linearly. It is preferable not to heat above 300°, as the increase in acidity is too rapid and becomes too great in the very highly thickened oils. A. Papineau-Couture

Colophony in varnishes and oil paints. R. Schwarz. *Farbe u. Lack* **1931**, 123–4.—The low price and many uses of colophony make it a very important raw material. The principles of its uses in gloss oils, rubbing varnishes, tung oil spar varnishes and ester gum are briefly outlined. G. G. Sward

Kauri gum in nitrocellulose lacquers. I. Solubility of kauri gum in mixed lacquer solvents. LEONARD S. SPACKMAN. *New Zealand J. Sci. Tech.* 12, 65–93(1930).—Kauri is sol. in (1) ansol to which may be added AmOAc or (and) C_7H_8; (2) petroleum distillate, used in mixts. with other solvents; (3) Cellosolve. AmOH is also used with these. All these are compatible with pyroxylin. This long paper is a treatise on using kauri with these in pyroxylin lacquers. D. THUESEN

Printing-ink patents. JOSEPH ROSSMAN. *Am. Ink Maker* 8, No. 8, 21–3; No. 9, 23–5, 41, 43; No. 10, 27, 29, 41; No. 11, 27, 29, 41; No. 12, 27, 29 (1930); 9, No. 1, 25, 27 (1931). E. J. C.

TiO_2 (SPEITEL) **18.** Separation and size distribution of microscopic particles (ROLLER) **2.** Use of vulcanized rubber waste as a fixing agent in bronze printing (RICE) **30.** Rubber conversion product [for use in varnishes or lacquers] (U. S. pat. 1,797,188) **30.** Drying apparatus for pigments (Ger. pat. 518,379) **1.** Purifying pitch, etc. (Brit. pat. 339,470) **22.**

JACOBI, WERNER: **Die Fabrikation von Wachstuch, amerikanischem Ledertuch, Wachstaffet, Maler- und Zeichenleinwand, Teertuch, unverbrennlichen Geweben, Linoleum, Linoleumersatz und Kunstleder.** Leipzig: A. Hartleben's Verlag. 182 pp. M. 4.50; bound, M. 5.50.

Green paint. P. N. SHURUIGIN. Russ. appl. 72,760, June 4, 1930. Dehydrated $CuSO_4$ is added, with agitation, to a mass of white lead and litharge ground in linseed oil after heating and recooling. The mass is then passed through a color mill, and water is added. The product is taken up in ground white lead and a soln. of rosin in gasoline.

Rust-resisting paint. CARL NITTINGER (to Carnitt-Rostschutz & Farbstoff G. m. b. H.). U. S. 1,795,962, March 10. A paint suitable for use on iron, wood or other surfaces is formed of a vehicle such as varnish and a pigment comprising finely ground coal slag about 80 and finely ground "electro-positive Zn" about 20%.

Anticorrosive and antifouling paints. N. J. SHIELDS. Brit. 339,128, Dec. 17, 1929. Paints are formed contg. over 25% by wt. of Hg oxide, with vehicles such as MeOH, shellac, turpentine, linseed oil and japan and pigments such as ZnO, Indian red or other Fe oxide pigments or red lead or other Pb compds.

Masking paste for use in sign painting, etc. ALBERT E. VAUGHN. U. S. 1,795,455, March 10. A pigment such as yellow ocher is mixed with an emulsion formed of honey 10, evapd. milk 8 and glycerol 6 parts and a small proportion of "sulfurated potassium"

Oil colors for printing, etc. FIRMA HERMANN FRENKEL. Ger. 518,322, Sept. 11, 1929. A strongly blown linseed oil having an acetyl no. of at least 100 is used as the vehicle.

Iron oxide pigments. I. G. FARBENIND. A.-G. (Bernhard Würzschmitt and Annemarie Beuther, inventors). Ger. 515,563, Dec. 5, 1928. A $Fe(OH)_2$-contg. ppt. is oxidized by O gas in presence of water or aq. salt solns. at temps. above 100° and with raised pressure. Thus, $Fe(OH)_2$ is pptd. from a $FeSO_4$ soln. by NaOH and the ppt. oxidized in an autoclave at 190–200° and 10 atm. to give a bright red pigment. Further examples are given.

Lead pigments. SWISS INVENTIONS SYNDICATE, LTD., and A. V. BLOM. Brit. 339,357, Sept. 7, 1929. A pigment consisting of a fine dispersion of Pb in Pb oxide is prepd. by melting an alloy rich in Pb (suitably an alloy contg. Pb 85, Sb 13 and Sn 2%) in a thin layer in an air-tight furnace in the presence of Ca resinate (suitably 0.5% the quantity of the alloy), maintaining the temp. just above the m. p. of the alloy, and creating a vacuum in the furnace so that streams of air are drawn into the furnace to oxidize the Pb of the alloy. A temp. of 280–310° is suitable with the specified alloy.

Ultramarine. V. F. OSMULSKII and M. P. RESH. Russ. appl. 59,674, Dec. 5, 1929. The black caustic obtained from spent sulfite liquor is evapd. to dryness, disintegrated, mixed with sulfur, kaolin and silica, calcined in crucibles or muffle furnaces and then worked over by usual methods.

Composition for colored pencils. V. M. RODIONOV and I. M. FEDOROV. Russ appl. 47,402, May 17, 1929. Graphite, talcum, etc., are added to the mass obtained in the prepn. of methyl violet by oxidation of $PhNMe_2$. The mass is then worked up by the usual methods after the addn. of a gum, such as gum tragacanth.

Drying oil products. J. SCHEIBER. Brit. 338,932, May 21, 1929. Products having properties generally similar to those of wood oil are obtained by heating oils of the linseed, soy bean and fish oil classes to 200° or somewhat higher with small quantities of catalysts such as H_2SO_4, $SbCl_5$, Al_2O_3, HgO, I bromide, Fe, Ni, Zn or Sn. The corre-

sponding fatty acids may be similarly treated and the products thus formed then esterified with glycol or glycerol or a mixt. of these.

Driers for paints, varnishes, etc. I. G. FARBENIND. A.-G. (Franz Pohl, inventor). Ger. 518,094, Oct. 26, 1927. See Brit. 311,716 (*C. A.* 24, 979).

Coloring nitrocellulose lacquers and plastics. I. G. FARBENIND. A.-G. Ger. 518,018, Sept. 24, 1929. Addn. to 515,057 (*C. A.* 25, 1692) and 516,315 (*C. A.* 25, 2011). The dyes specified in Ger. 515,057 and 516,315 are used in conjunction with dinitrodiphenylamines. Green colors fast to light are so obtained.

Protective coating on iron, wood or other materials. WALTER BAUR. U. S. 1,795,703, March 10. Protection from the atm. is effected by applying, at ordinary temp., a mixt. of castor oil and 5–10% metal oxides such as those of Pb, Mn, Co or Zn with an addn. of solvents consisting of easily drying oils such as turpentine or naphtha followed by heating and "burning in" the coating by a suitable hot air blast. App. is described.

Protective coatings on metal pipes, etc. HEROLD A.-G. Brit. 338,983, March 9, 1929. The material to be coated is preliminarily heated to the m. p. of a fusible intermediate artificial resin such as one formed from phenol or urea and formaldehyde and such a material is applied (without a solvent) in pulverulent form (either as a dust or in suspension in water or other non-solvent liquid or by rubbing on as a solid block). During hardening the coated surface may be treated with a solvent or solvent vapor and fillers also may be added.

Reducing the viscosity of nitrocellulose solutions. WM. C. WILSON (to John S. Stokes). U. S. 1,795,918, March 10. A phenolic condensation product contg. an active methylene compd. such as $(CH_2)_6N_4$ is added to a nitrocellulose lacquer to lower its viscosity.

Cellulose-covered wire gauze. KALLE & Co. A.-G. (Adolf Dulitz, inventor). Ger. 515,531, June 28, 1928. The gauze is dipped alternately into a cellulose ester soln. and a weakly acting swelling agent. The product may be coated with a thin layer of dil. nitrocellulose. In the example, a wide-meshed wire gauze is dipped into acetylcellulose lacquer and, when dry, into aq. alc. as swelling agent. The operations are repeated until the required thickness is attained. C_6H_6 or PhOH may be used instead of aq. alc. The finished product may be rendered weather proof by a coating of 2–3% tricresyl phosphate.

Linoleum. E. CLAXTON (to Armstrong Cork Co.). Brit. 338,965, Oct. 15, 1928. The oxidizable components of a linoleum cement contg. a siccative oil are first substantially completely oxidized (suitably as described in Brit. 305,656, *C. A.* 23, 4837) and a coagulant is added to the cement (about 1% of H_3BO_3 being preferred as coagulant), and the material is mixed with suitable fillers. Numerous details of compns. and procedure are described. Brit. 338,978 specifies the use of a "delayed action" coagulant such as dehydrated boric acid in the form of metaboric or pyroboric acid or boric anhydride, or urea.

Resins from cellulosic material. UCHEBNO-OPUITNUI ZAVOD MOSKOVSKAGO TEKHNIKUMA ZHIROVOI PROMUISHLENNOSTI "TEKHZHIRZAVOD." Russ. appl. 56,420, Oct. 15, 1929. Sunflower husks are heated under pressure with water or an aq. soln. of alkali followed by hydrolysis with mineral acids and extn. by the usual methods.

Artificial resin compositions for lacquers, etc. I. G. FARBENIND. A.-G. Brit. 339,271, Sept. 3, 1929. Homogeneous products are prepd. by mixing, in soln. or otherwise, a polymerization product of a vinyl ester such as polyvinyl chloride with the condensation product of a phenol deriv. and aldehyde (such as the product from anisole and CH_2O) or the like. An example is given for making a lacquer with C_6H_6 as solvent.

Molding synthetic resins. A. V. KELLER. Brit. 338,915, Aug. 28, 1929. Decorative articles are made from synthetic resins by placing lace or other fabric (without preliminary impregnation) between a covering sheet and backing of initial condensation product and heating the materials under pressure. Cf. *C. A.* 25, 610.

Synthetic resins such as urea-formaldehyde resins. I. G. FARBENIND. A.-G. Brit. 338,937, July 29, 1929. Condensation of reacting materials such as urea or thiourea and CH_2O for obtainment of non-inflammable products is effected in the presence of org. solvents formed at least mainly of haloaryl substituted aliphatic alcs. such as mono- and di-bromobenzyl alcs. and chlorobenzyl alcs., and preferably in the presence of an acid-reacting substance such as oxalic acid or HOAc (the reaction being accelerated by heating). Numerous examples with details of procedure are given, for producing products suitable for making lacquers, molded articles, etc.

Synthetic resins. J. M. WEISS. Brit. 338,845, July 10, 1929. Polymerization of coumarone, indene and their homologs is effected by using as the polymerizing agent

a mixt. of an adsorbent earth such as fuller's earth and an acid sulfate of a tervalent metal such as acid ferric sulfate. Various details of procedure are described.

Synthetic resins. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON HOUSTON. Fr. 37,234, July 19, 1929. Addn. to 654,175 (*C. A.* **23**, 3822). The production of artificial resins of the alkyl kind combined with drying oils is described. Thus, a mixt. of glycerol and phthalic anhydride is heated progressively to 200°, a mixt. of phthalic anhydride and one or more fatty acids derived from drying oils (china wood oil, linseed oil or Perilla oil) is added and the heating is continued until the foam disappears, then the desired amt. of drying oil is added, *e. g.*, 10–50% of the wt. of the resin. It is preferable to incorporate the drying oil before complete condensation has taken place. Instead of acids from a drying oil, one or more oxidizable unsatd. acids such as oleic acid, stearic acid or linoleic acid may be used. In another example an unsatd. fatty acid, *e. g.*, an acid derived from linseed oil, is heated with glycerol to 200–250°, linseed oil is then added until a clear soln. is obtained. The soln. is mixed with phthalic anhydride and heated further, The compns. of resin and oil are sol. in acetone, AcOBu, BuOH, triacetin, etc., and may be used as a varnish, etc., or incorporated with fillers for making molded objects.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Little-known Brazilian oil seeds. F. W. FREISE. *Seifensieder-Ztg.* **58**, 131–2 (1931); cf. *C. A.* **24**, 1238.—F. tabulates the consts. of 27 varieties of little-known Brazilian oil seeds, giving the source, popular and botanical names and the time of ripening. P. ESCHER

The fatty oil of seeds of Colchicum autumnale L. G. GAAL. *Magyar Gyógyszerészt. Társaság Értesitoje* **6**, 149–67(1930).—The consts. of the oil are: d_{15} 0.9104–5, n_D^{20} 1.4723, acid no. 14.76, sapon. no. 199.0 9.8, acetyl no. 12.3, Reichert-Meissl no. 2.41, Polenske no. 0.32, Hehner no. 91.6–92.1, I-Br no. 92.47, satd. fatty acids 12.73%, glycerin 10.8%, mol. wt. 269.5. The fatty acids contained 2.1% raw phytosterin. The presence of arachidic acid could not be demonstrated. Daturic acid was found in the oil.

S. S. DE FINÁLY

Experiments with the shipment of some tropical products containing oil in pressed bales. IR. W. SPOON. *Ber. Afdeel. Handelsmuseum Ver. Koloniaal Inst.* No. **56**, 28 pp.(1930).—With copra the results were satisfactory, there being no loss of oil and only a small increase in free fatty acids. The results with earth-nuts and rubber-seed kernels were very unsatisfactory, as both had suffered from the pressing and the percentage of free fatty acids had increased considerably. J. C. JURRJENS

New compounds produced during the hydrogenation of fish oils. II. The formation of the higher alcohols. SEI-ICHI UENO AND RIICHIRO YAMASAKI. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding 35–7(1931); cf. *C. A.* **25**, 612.—One kg. of unsapon. matter was washed with methanol to sep. hydroxy compds. from hydrocarbons. After evapn. of the methanol the residue was taken up with ether, treated with $Na_2S_2O_3$ and phenyl hydrazine to remove aldehydes and ketones and then washed, dried and evapd. The higher alcs. obtained were fractionated by distn. and the fact was confirmed that the unsapon. volatile matter produced during hydrogenation contains iso-aliphatic C_9, C_{10} and C_{12} primary alcs. of the satd. and olefin series together with hydrocarbons of the iso-paraffin and olefin series. E. SCHERUBEL

Catalytic fat hardening. I. Progressive hardening decreases the speed of hydrogenation. II. Selective hydrogenation of fish oils. L. UBBELOHDE AND H. SCHÖNFELD. *Z. angew. Chem.* **44**, 184–7(1931).—The decreasing speed in progressive hydrogenation of oils is not due to the catalyst, since it can be used over several times; each time it shows a high speed at the start and slows up toward the end. Nor is it due to the concn. in the oil of the double C bond, since linseed oil and fish oils are hardened less rapidly than cottonseed oil. It is due to the increasing concn. of satd. acids and to the manner of hydrogenating. By detg. the insol. bromides, formed by highly unsatd. acids, at the different stages during fish-oil hardening, U. and S. confirmed the fact that clupanodonic acid can be reduced completely to less unsatd. acid without forming stearin, by means of a gentle hydrogenation, reduction of the amt. of Ni, temp. and agitation The fish-oil odor disappeared at I no. 95 when rapidly hardened and the clupanodonic acid at I no. 80–90; slow hardening (45–50 I nos. per hr.) showed only 0.5% of the highly unsatd. clupanodonic acid remained at I no. 120. P. ESCHER

Solubility of fats in various solvents. Solubility of Tsubaki oil and rape oil in ethyl alcohol. K. HASHI. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding 64–6, 66–7 (1931).—The soly. of refined and bleached Tsubaki oil (*Camellia*, family Theaceae) as well as that of rape oil was detd. in various concns. of ethyl alc. by heating known amts. of oil and alc. of different concns. in closed tubes and observing the temp. at which both layers turned clear. The turbidity temp. was read during slow cooling. The results are tabulated and expressed in graphs. P. ESCHER

An installation for continuous washing with alcohol in refining oils and obtaining a high percentage of fatty acids and their esters. OTTO KREBS. *Chem. App.* **18**, 15–6, 49–51(1931).—A system is described for washing fatty acids from oils with alc. The alc. removes the acids and is recovered in a rectifying column. M. C. ROGERS

Intramolecular rearrangements when hydrogenating esters of fatty acids with one double bond. II. A. STEGER AND H. W. SCHEFFERS. *Chem. Umschau Fette, Öele, Wachse u. Harze* **38**, 61–6(1931); cf. *C. A.* **25**, 2315.—A Δ^9-elaidic, a Δ^9-oleic and a Δ^9-oleic Et ester were partially hydrogenated with Ni at 180° to an I no. of 55, at which point a max. of solid unsatd. acids is formed. The products were analyzed for their solid and liquid acids by Twitchell's alc. method, sepd. into their individual acids by fractional crystn. in different solvents, and the constitution of each acid was detd. by ozonization and analysis of the ozonides for m. p., proximate compn. and sapon. no. The double bonds in Δ^9-elaidic and Δ^9-oleic acids are shifted during hydrogenation from Δ^9 toward both sides to Δ^{10} and Δ^8, a greater amt. being formed of the former than of the latter; the elaidic acid forms less of the Δ^{10}- and Δ^8-elaidic acids than oleic acid, and thus it may be assumed that the principal shifting of the double bond occurs in the liquid oleic acid and that the first-formed Δ^8- and Δ^{10}-oleic acids are later converted into Δ^8- and Δ^{10}-solid elaidic acids. The Δ^6-oleic Et ester shifts its double Δ^6 bond also to its neighboring C atoms, forming Δ^5- and Δ^7-oleic acids and possibly also the corresponding Δ^5- and Δ^7-elaidic acids. No conclusions could be drawn with respect to the manner in which the bonds of solid unsatd. acids change during hydrogenation, since hardening was stopped at the point of their max. formation. P. ESCHER

The spontaneous ignition of commercial oleic acid. PAUL ERASMUS. *Allgem. Öl- Fettztg.* **27**, 309–12, 345–8, 367–8, 408–9(1930). –Oleic acid manufd. from bone fat contained no highly unsatd. acids. It was very susceptible to spontaneous ignition in the Mackey app. When the anhydrides present were removed it was no longer susceptible to spontaneous ignition. The removal of the anhydrides also prevented the darkening of the oleic acid on atm oxidation. Addn. of the isolated anhydrides to an oleic acid which was not spontaneously ignitable caused it to take on this property. The substance causing the spontaneous ignition was identified as γ-stearyl lactone. This substance on oxidation yields ketonic acid, which in turn gives up O_2 easily to form the lactone again. The addn. of 0.05% of γ-stearyl lactone to oleic acid causes it to become spontaneously ignitable. The presence of Fe was found necessary to bring about this result. Removal of Fe from a spontaneously ignitable oleic acid caused it to lose this property. Addns. of small quantities of Fe oleate to an oleic acid not spontaneously ignitable did not show any effect. When larger amts. (0.5%) were added it became spontaneously ignitable. Conclusion: The lactones are O_2 carriers, requiring the presence of Fe as catalyst, and are a cause of the spontaneous ignition of oleic acid. The addn. of 1% linolic and linolenic acids (lactone free) to an oleic acid not spontaneously ignitable caused it to become so. W. F. BOLLENS

Oleiferous Allanblackia. Chemical composition of Allanblackia floribunda Oliv. J. PIERAERTS AND SERGE VLASSOV. *Mat. grasses* **22**, 8975–7(1930).—Addnl. analysis has been made supporting previous conclusions that this plant is the cheapest and most satisfactory raw material for the *manuf. of* pure or technical *stearic acid*. P. T.

Thermodynamics in the soap industry. K. LÖFFL. *Seifensieder-Ztg.* **58**, 127–8, 152–3(1931).—L. discusses the calcn. of the total calories required for boiling and drying soaps. Spray drying shows simplicity of app. and least heat consumption. P. E.

Preparation for splitting fats. G. S. PETROV. Russ. appl. 62,843, Jan. 23, 1930. Addn. to pat 18,855. Fat-splitting agents are prepd. by sulfonation of highly hydrogenated fats or fatty acids, excluding hydrogenated castor oil.

Oils and fats. PETER FRIESENHAHN. Ger. 515,769, May 28, 1925. Addn. to 365,160. The hydrated phenols of 365,160 for prepg. emulsions or solns. of oils and fats are supplemented or replaced by alcs. formed by the hydrogenation of unsatd. hydrocarbons obtained from the cracking of acid resins or from the residual pitch of aliphatic raw material distns.

The concentration or drying of masses containing fatty oils. L. AUER. Hung. 101,164, May 28, 1925. Masses are concd. or dried in an atm. contg. less O than does air.

Preventing oxidation of oils, etc. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 695,119, May 6, 1930. The oxidation of oils, fats, waxes, etc., is prevented by adding 0.5–1% of phenyl-α-naphthylamine.

Extracting oil from blubber, meat, bones, tongues and other parts of whales, etc. C. O. JOHNSON. Brit. 339,305, Aug. 31, 1929. In a wet rendering process, the materials are submerged in water which is kept boiling under pressure during the digestion by introduction of steam. App. and various details of procedure are described.

Apparatus for extracting oil from olives, etc. Soc. JEANJEAN ET CASAS. Fr. 37,352, Aug. 9, 1929. Addn. to 654,217 (*C. A.* **23**, 3824).

Reaction products of cashew nut shell oil. THE HARVEL CORP. Ger. 518,424, June 4, 1927. See Brit. 272,510 (*C. A.* **22**, 1863) and 275,574 (*C. A.* **22**, 2285).

Soap. JEAN GNAEDINGER. Fr. 37,464, Sept. 27, 1929. Addn. to 665,425 (*C. A.* **24**, 984). The α-abientinic acid is converted to the β-form which is more stable before combining it, by the aid of catalysts, with unsatd. oils of the fatty series to form a soap.

Soaps. I. G. FARBENIND. A.-G. (Otto Ambros and Anne Nies-Harteneck, inventors). Ger. 518,019. Mar. 13, 1928. Products yielding stable foams and emulsions are prepd. by adding soft or hard fish roe or prepns. thereof to soaps or saponaceous materials. A suitable addnl. substance may be prepd. by removing fat from soft fish roe by means of an org. solvent and then drying, or the active material may be extd from the roe with dil. alkali.

Dry-cleaning soap. LEO R. HUBBARD (to Camille Dreyfus). Can. 309,361, Mar 10, 1931. A detergent adapted for the dry cleaning of fabrics comprises a mixt. of oleic acid 1, cyclohexanol 1, CCl_4 1, ammonia of (26° Bé.) $^1/_8$ and water $^1/_2$ part.

28—SUGAR, STARCH AND GUMS

J. DALE

Quality of the mineral fuel received by sugar factories for the campaign 1929-30. I. B. MINTZ. *Nauk. Zapiski Tsukrovoi Prom.* **10**, 225–35(1930).—A report.
V. E. BAIKOW

Movement of nitrogenous substances in sugar manufacture during the campaign of 1929-30 at the Usinskii sugar factory. B. A. LYASKO. *Nauk. Zapiski Tsukrovoi Prom.* **10**, 23–38(1930).—From a no. of analyses made during the campaign L. shows the amt. of noxious N represents about $^1/_3$ of the total N of the beet. At the diffusion battery about $^1/_3$ of the total N, $^4/_5$ of the albuminum N and $^1/_{10}$ of the noxious N are eliminated, while ammonia and amide N go almost entirely into the diffusion juice. 96.5% of N in sirup is of the noxious type. Ninety % of the noxious N passes into the final molasses with 10% eliminated in the diffusion battery. Ten tables and 2 diagrams are shown.
V. E. BAIKOW

Experiments in the harvesting of burned cane. III. P. O. J. 213 cane. H. H. DODDS AND P. FOWLIE. *Proc. S. African Sugar Tech. Assoc.* **1930**, 122–32(1931); *cf. C. A.* **24**, 3125.—It is shown in a no. of tables and graphs that the variety P. O. J. 213, like the Uba cane, deteriorates more slowly after being burned than when it is not fired. The burned cane keeps better if left standing than after it is cut. The differences between burned and unburned canes are even greater than in the case of Uba, and unburned cane must be taken to the mill without delay, while burned cane may be kept for about a week. But in fields which have been burned over, the supply of org. matter must be maintained by fertilizing.
F. W. ZERBAN

Determination of small proportions of invert sugar in raw sugars. LEWIS EYNON AND J. HENRY LANE. *J. Soc. Chem. Ind.* 50, 85–6T(1931); cf. *C. A.* 17, 1400, 2091; 18, 763.—The original tables were calcd. only for products contg. not less than 0.3% invert sugar. A new table is presented for a range of 0–0.464% invert sugar. Twenty-five g. of the sugar plus 0.1 g. invert sugar in the form of the standard soln. is dissolved to 100 ml. This soln. is titrated against 10 ml. Fehling soln. by the standard method previously described. It is unnecessary to clarify with $Pb(OAc)_2$ or to remove lime salts with $K_2C_2O_4$, because the same results are obtained without their use.

F. W. ZERBAN

Measurement of color in solutions of white sugars. J. A. AMBLER AND S. BYALL. *Ind. Eng. Chem., Anal. Ed.* 3, 135–6(1931).—The measurement of the colors of white sugars was placed on a reproducible, accurate basis by matching the colors of water solns. of the sugar against a standard made by dilg. 10 g. of Balch's No. 5 maple sirup color standard soln. (*C. A.* 24, 2630) with water to 100 cc. For the detn. of color of hard candies made from the sugars the candies were dissolved in water and the colors of the solns. matched against a No. 9 maple sirup standard soln., dild. in the same way as the No. 5. The color of the barley candy is not related to that of the original white sugar.

F. W. ZERBAN

Impurities in white sugars. I. Determination of phosphorus. S. BYALL AND J. A. AMBLER. *Ind. Eng. Chem., Anal. Ed.* 3, 136–7(1931).—The importance of traces of [illegible] necessitates analytical methods of greater sensitivity. Total P_2O_5 is detd. in the HNO_3 soln. of the residue obtained by ashing in the presence of Na_2CO_3; inorg. P_2O_5 is detd. directly in a water soln. of the sugar, and org. P_2O_5 is found by difference. The Briggs modification (*C. A.* 16, 3493) of the Bell and Doisey ceruleo-molybdate method (*C. A.* 14, 3685) detects as little as 0.3 p. p. m. of P_2O_5 in a 10-g. sample. Analytical results on 26 samples of white sugars show up to 1 4 p. p. m. of inorg., and up to 45.6 p. p. m. of org., P_2O_5.

F. W. ZERBAN

Recovering of ammonia in beet-sugar manufacture. A. I. VOSTOKOV AND M. P. KOTLYARENKO. *Nauk. Zapiski Tzukrovoi Prom.* 10, 241–9(1930).—The methods for recovering NH_3 from evapd. water from beet juice are described. The product is a high-grade *fertilizer*.

V. E. BAIKOW

The German report on the Oxford sugar method. OSKARI ROUTALA. *Acta Chemica Fennica* 3, 94–5(1930).—If sugar beets were not treated immediately after picking the yield of sugar was low and there was considerable inversion, especially if the beets were stored in a warm place. The yield was also low if the beets were frozen. The Oxford sugar method consists in the rapid picking, cutting and drying of the sugar beets to preserve the sugar content for later use. The beets were cut into very small pieces and dried in a 3-compartment oven at 60–70° for 1 hr. The dry beets had 60–70% sugar, compared to 7–8% in the undried beets. Very little inversion was found. The drying affected the protein and protoplasmic content of the beets in such a way that little of these substances was found in the sugar solns. The sugar from the dried beets was extd. very readily by water. The soln. turned black when 0.2–0.3% of Ca as oxide, pectate, oxalate or phosphate was added. Addn. of activated charcoal and centrifuging gave a colorless sugar soln. The molasses obtained was sweeter than ordinarily, because of a higher invert-sugar content. The German investigation comm. reported that the procedure is as yet not industrially profitable since the change to the new equipment is costly.

S. A. KARJALA

Experiments on raw sugar with Russian activated carbon. M. P. KOTLYARENKO AND N. K. KONIBOLOTZKII. *Nauk. Zapiski Tzukrovoi Prom.* 10, 102–11(1930).—The decolorizing power of the Russian activated C is higher than that of Norit-Standard, Amsterdam, 1926. The adsorption of colloids and ash by Norit is smaller than that by Russian C. The colloids and ash are not retained by the C and are almost entirely washed back into the thick juice. The wash (sweet) water must be given a preliminary treatment to eliminate the ash and colloids before it is mixed with a sirup. The max. regenerating effect of activated C was obtained by thermal and HCl treatment.

V. E. BAIKOW

The quality of the sweet (wash) water from the bone-black filters. M. I. NAKHMANOVICH AND I. F. ZELIKMAN. *Nauk. Zapiski Tzukrovoi Prom.* 10, 51–74(1930).—From a no. of expts. the following conclusions can be drawn: With decrease of the density, the proportion of non-sugars increases. The sweet water washes out from the chars the col[illegible] matters adsorbed in the early stages of the filtration. Washing should be [illegible] when the sweet water decreases to 2.5 Brix (1.5–1.6% of sugar).

V. E. BAIKOW

Norit installation at the Khutor-Mikhailovskii sugar refinery. G. I. ZHURIK. *Nauk. Zapiski Tzukrovoi Prom.* **10,** 86–102(1930).—A description. V. E. BAIKOW

Regeneration of the bone chars. N. S. VOLKOV. *Nauk. Zapiski Tzukrovoi Prom.* **10,** 294–307(1930).—Regeneration of bone chars can be divided into 2 parts: (1) boiling for a certain period of time in the same vol. of water, and (2) washing with clean water for a limited time. With poor quality of water, the time of boiling and amt. of water should be increased. While the water dissolves mineral salts and org. matters, the bone black adsorbs coloring matters from the water. If the temp. of the wash water is decreased from 90–95° to 55–60°, the amt. of water must be increased 30–40%. Washing with condensed water has the advantage of decreasing the amt. of steam. The chem. control of the regeneration consists in checking and comparing the mineral residue of the wash waters before and after washings.
V. E. BAIKOW

Prospects and advantages of rotary filters in sulfitation factories. W. H. FOSTER. *Proc. S. African Sugar Tech. Assoc.* **1930,** 71–6(1931).—The sucrose (2%) lost in filter cake in Natal is higher than in other countries. Higher diln. of settlings is not economical. Washing in the presses gives indifferent results, and furnishes a sloppy cake. The use of filter aids in sufficient quantity is too expensive. Double filtration through the presses reduces the sucrose loss in filter cake, but also the purity of the filtrate and the boiling house efficiency. Double settling is being practiced, but it requires too much steam for evapn. The Mauss continuous rotary vacuum filter has been tried in various ways. The 2nd operation in double filtration can be carried out more economically with the rotary filter, the machine being particularly suitable to this type of work. The low purity of the 2nd filtrate is an undesirable feature of the process. The solid content of the settlings is rather low for the successful direct operation of the rotary filter. Should a thickened sludge be possible at low cost, the filter offers considerable advantages over the filter press as regards economy in labor and cloth, increased sugar recovery and greater cleanliness. The floor space required is much greater than in the case of filter presses.
F. W. ZERBAN

Metafiltration in the sugar industry. ANON. *Intern. Sugar J.* **33,** 18–20(1931).—It is a well-established fact that the filtration employed in the carbonatation process is responsible for the increased yield, and the better quality of the sugar as compared with the defecation or the sulfitation process. Filtration app., whether of cloth, sand, wire gauze or rings as in the case of the Metafilter, act simply and solely as a support to the solid matter which it retains. The filtering elements of the Metafilter are made up of thin brass rings $^7/_8$" outside and $^5/_8$" internal diam. The rings are piled one upon another to form a tube so that a 1-in. run of filtering elements is composed of some 30 rings. Alternate rings carry a light embossing on each face exactly 0.002 in. high, which provides a gap of this thickness between each pair of rings. The rings are strung on a fluted rod which acts as a support and provides drainage channels, the rings being pressed together by screw pressure from the end. An ingenious aspect is an arrangement to rotate the whole filter body *en bloc*. In operating the Metafilter on filtering juices in a defecation or sulfitation factory it is necessary first to precoat the column of rings with a thin film of kieselguhr. It was found in Java that an addn. of 0.5% on the Brix of the heavy liquor being filtered was all that was necessary to obtain a fairly rapid flow. In 60 min., in one run, 1000 l. of 55–60 Brix juice at a temp. of 70° was filtered with a filtering area of 2.2 sq. m., corresponding to a capacity of 7.5 l. per sq. m., per hr., a very high rate of filtration.
W. L. OWEN

Loss in polarization of Natal raw sugars on storage. L. BLACKLOCK. *Proc. S. African Sugar Tech. Assoc.* **1930,** 105–7(1931).—Several cases of excessive deterioration of Natal sugars call for remedial measures. The safety factor should be kept low, by drying if necessary. The sugar should be of uniform grain and not acid. The mill must be kept in sanitary condition. Mixing of high-grade with low-grade sugars should be avoided. Storage and transport conditions should be as perfect as possible, low humidity and low temp. being essential.
F. W. ZERBAN

Palmyra palm and its uses in gur manufacture. M. R. GOKARN. *Poona Agr. Coll. Mag.* **21,** 241–52(1930).—The manuf. of gur (crude sugar) from the juice obtained by tapping the immature nuts of the palmyra palm (*Borassus flabelifer*) is described. The best yields of juice are obtained from the female spathes, the av. yield per tree ranging from 60 to 100 gallons per season. Saccharimeter readings on several samples of palmyra juice ranged from 11° to 13° Brix as compared with 13.5° to 18° Brix for coconut juice. There was no marked difference in the saccharimeter readings on the juice from the male and female palmyra spathes. Two samples of the crude sugar contained 2.10 and 2.61% glucose and 86.68 and 83.51% sucrose, resp.
K. D. JACOB

New sources of inulin. E. YANOVSKY AND R. M. KINGSBURY. *J. Am. Chem. Soc.* **53**, 1597–601(1931).—Three new sources of inulin (I) are discussed: Camas roots (*Quamasia guamash* (Pursh)•Coville, (*Camassia esculenta* (Lindl.), of which 200 g. gives 30–1 g. of I; *Allium nuttallii* S Wats, a variety of wild onion, 200 g. of which gives 25 g. I; and *Balsamorrhiza sagittata* (Pursh) Nutt, belonging to the family Compositae, 100 g. of which gives 3.2 g. I. The sp. rotation of I from these sources ranged from —28° to —33°; all products were sol. in H_2O and dil. EtOH. In the light of this work and that of Chevastelon (*J. pharm. chim.* 2, 83(1895)), it appears that there is no correlation between the sp. rotation and the soly. of I. No claim is made that any of the products described was a definite chem. individual. C. J. WEST

Measurement of consistency of starch solutions. J. C. RIPPERTON. *Ind. Eng. Chem., Anal. Ed.* **3**, 152–4(1931).—The swell of starches is measured by pouring the starch suspension, prepd. by a standardized procedure, into water in a cylinder, allowing it to stand and measuring the vol. occupied by the starch granules on the next day. It was found that the product of concn. and swell, plotted against the viscosity, furnishes a curve which may be used to evaluate starches without a viscosity detn. The method gives best results with starches showing large swell, like potato, sago and arrowroot starch. F. W. ZERBAN

Potash fertilizer for sugar beets (WAGNER) **15**. The change in x-ray spectrum of inulin on swelling in water (KATZ, DERKSEN) **2**.

Sugar Abstracts (*New journal*). Published by the Palmer Publishing Corp. of New York, 153 Waverly Place, New York City. Appears as a part of *Facts About Sugar* and also as a separate journal. Vol. 1, No. 1 appeared in Jan., 1931. Price, $5 per year.

New Zealand-made leather. P. WHITE. *New Zealand J. Sci. Tech.* **1930**, 283–7; *J. Intern. Soc. Leather Trades Chem.* **14**, 573.—Results of density, water absorption and wear tests are given. H. B. MERRILL

Gas poisoning in the leather industry. A. GOLDENBERG. *Vestnik Kozhevennoi Prom. i Torgovli* (*Vestnik of Leather Ind. and Trade*) **1929**, No. 7/8, 431–4; *J. Intern. Soc. Leather Trades Chem.* **14**, 488–90.—A fatal poisoning occurring when workmen entered an empty tan vat is ascribed to HCN, produced from amygdalin of pine bark by enzyme action. Under certain manipulative conditions this gas may form a layer in the bottom of the vat when the liquor is drawn away. This may be dispersed by a water jet. Safety rules are given H. B. MERRILL

Stretching tests for leather. G. A. BRAVO. *Boll. ufficiale staz. sper. ind. pelli mat. oncianti* **8**, 130–41(1930); *J. Intern. Soc. Leather Trades Chem.* **14**, 385.—Samples cut from adjacent positions in the same skin show such variations that it is dangerous to draw conclusions except from a large no. of detns. A stretching force below that required for rupture causes permanent elongation. The relation between elongation and contraction in width and thickness is not the same as that obtained with isotropic substances. Simple rupture and tearing rupture (in a direction not at right angles to the strain) are distinguished. H. B. MERRILL

Estimation of fat in leather. P. KOPELIOVICH. *Vestnik Kozhevennoi Prom. i Torgovli* (*Vestnik of Leather Ind. and Trade*) **1928**, No. 4, 147. *J. Intern. Soc. Leather Trades Chem.* **14**, 578.—Extn. with petr. ether for 6 hrs. (36 siphonings), without previous drying of the leather, is advised. H. B. MERRILL

Determination of water in vegetable leather. R. FARADAY INNES AND J. M. COSTE. *J. Intern. Soc. Leather Trades Chem.* **15**, 126–36(1931).—Inaccuracies in the oven-drying method are studied. Factors considered are time of heating, pressure and temp. (vacuum at 98° *vs.* air at 110°), and grease content of the leather. Many of the findings

are contradictory, and it is concluded that the accuracy of the detn. of water in vegetable leather by the oven method cannot be guaranteed, no matter what the exptl. conditions, unless the grease content of the leather is extremely low. Regain in wt. of oven-dried samples stored over concd. H_2SO_4 is ascribed to adsorption of air. H. B. MERRILL

Irgitan and its use in dyeing chrome leather. J. G. GEIGY. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* **8**, 154(1930); *J. Intern. Soc. Leather Trades Chem.* **14**, 438.—Methods of application are described. H. B. MERRILL

Waterproof finishes [lacquer finishes for leather]. D. WOODROFFE. *Leather Trades Review* **1930**; *J. Intern. Soc. Leather Trades Chem.* **14**, 318.—A discussion. H. B. MERRILL

Hydration of animal skin by the volume change method. IV. Effect of various factors on the hydration of calf skin. EDWIN R. THEIS AND F. T. BENTON. *Ind. Eng. Chem.* **23**, 367–70(1931); cf. *C. A.* **23**, 2319.—The dilatometer method has been improved so as to measure hydrations quantitatively in ml. Postmortem changes reduce hydration and hasten the onset of degenerative dehydration. The onset of degenerative dehydration is prevented by salts and antiseptics, which indicates that bacterial action is responsible. Hydration, though in reduced amt., takes place in satd. solns. of salts, indicating that the wt. loss accompanying curing is due to removal of free rather than bound water. Hydration in satd. salt and alkali solns. follows the order: LiCl, (NaCl + Na_2CO_3) < $MgSO_4$ < NaCl < 0.05 *N* NaOH < $Ca(OH)_2$ + excess lime < H_2O, $Ca(OH)_2$. With dry-cured skin, NaCl in low concn. (2–4%) hastens the attainment of max. hydration but also hastens the onset of degenerative dehydration; in moderate concns. (8–10%) it delays the attainment of max. hydration without diminishing its extent, and inhibits dehydration; in high concns. (15–20%) it decreases the extent of hydration. Hydration increases with the ratio of water to the skin in the total exptl. system, and decreases with increasing temp. (again contrary to the effect on swelling). Increase in sp. gr. by the displacement method can be used to measure hydration. H. B. MERRILL

Physicochemical differences of hide powder by sex. T. TADOKORO AND K. YOSHIMURA. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding 37–8(1931).—Hide powder prepd from bull hide showed the following differences from that prepd. from cow hide: greater "acid-producing power" in neutral salt soln.; greater tannin absorptive power; less I_2 absorptive power; less swelling capacity in salt solns. (no difference if hide powders are purified) H. B. MERRILL

Microscopic study of the effects of cold temperatures upon skins and hides. FRED O'FLAHERTY AND WM. T. RODDY. *J. Am. Leather Chem. Assoc.* **26**, 172–80(1931) No damage was observed that could be attributed directly or indirectly to low or sub freezing temp. Keeping skins or hides at low temp. has a tendency to dehydrate them, which also aids in their preservation. Frozen skins should never be flexed, and should be allowed to thaw before soaking. H. B. MERRILL

Columbian hides. V. A. LATHOM SHARP. *Leather Trades Review* **1930**, 889–92; *J. Intern. Soc. Leather Trades Chem.* **14**, 587.—Methods of cure and preservation are described. H. B. MERRILL

Investigations on animal skin. GEORG GRASSER AND HIROSHI OHOKI. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. 2, 263–74(1930).—The time of hydrolysis of skins of different species in solns. of acids, bases and salts is tabulated. H. B. MERRILL

Investigations on gelatin and skin. GEORG GRASSER AND HIROSHI OHOKI. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. 2, 275–84(1930).—The peptizing effects of numerous salts are listed. H. B. MERRILL

Cultivation and tannin content of Caesalpina coriaria (divi-divi) in [former] German E. Africa. T. MARX. *Tropen* **33**, 100–5(1930); *J. Intern. Soc. Leather Trades Chem.* **14**, 587–8.—The tannin content is fair after 9 years' growth and excellent after 15 yrs The percentage of tannin compares favorably with that of Indian divi-divi. H. B. M.

Problem of tannery waste. D. JORDAN LLOYD. *Leather World* **22**, 1102–5(1930).—Products are enumerated and current practice for their disposal is discussed. H. B. MERRILL

Tanning materials and their characterization. II. Organic tanning materials. GEORG GRASSER AND HIROSHI OHOKI. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. 2, 243–61(1930); cf. *C. A.* **24**, 4951.—Contraction temp. and time required for complete hydrolysis on boiling are tabulated for hide and gelatin tanned with a large no. of tanning materials, including natural tannins, syntans, aldehydes, phenols and their derivs. The effect of added salts and of solvent (in case of aldehydes) is studied. No general relationships are found and no conclusions drawn. H. B. MERRILL

Analytical control of sulfonated oils used in the tannery. M. GERONAZZO. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* **8**, 142–50(1930); *J. Intern. Soc. Leather*

Trades Chem. **14**, 373; cf. *C. A.* **22**, 2485.—The procedure devised for sulfonated castor oil has been applied to sulfonated animal and fish oils. The results are sufficiently precise for technical purposes. H. B. MERRILL

Combined working of two tanning materials on gelatin and animal's skin. Chemical investigation of combination tannage. GEORG GRASSER AND MASATAKE ICHISE. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. 2, 319–48(1930).—The contraction temp. of the skin and fh. p. of gelatin tanned successively with 2 tanning materials are tabulated. H. B. MERRILL

Mangrove as a tanning material. T. A. BUCKLEY. *Malayan Forest Records* **1929**, No. 7; *J. Intern. Soc. Leather Trades Chem.* **14**, 277–8.—Analyses show the variations in tannin content in bark from different species, different trees and different parts of the same tree. Great variations exist; the average compares unfavorably with Madagascar and E. Africa mangrove. *Rhizophora mucronata* has very high tannin content (28% of moist bark); the more plentiful *R. conjugata* contains only about 16%; *Carapa obvata* is the species richest in tannin, but its exts froth badly. Bark should be extd. as soon as stripped; there is a gain in tannin on drying, but this is offset by objectionable darkening of color. The tannin content tends to increase from the bottom to the top of the tree, and is highest in older, bigger trees. H. B. MERRILL

The Pavlovitsch alkaline tanning method for the preparation of sole leather. L. KEIGUELOVKIS. *Ledertech. Rundschau* **1930**, 81; *J Intern Soc Leather Trades Chem.* **14**, 574.—The leather is tanned first with quebracho at p_H = 8 – 7.5 for 6 days, the concn. and temp. being gradually increased; then with oakwood ext at p_H = 3.8 – 4.0. Analyses and wear tests show the leather so made to be normal H. B MERRILL

Tanning small fur skins. O. DUJARDINE. *Leather Manufacturer* **41**, 260–1(1930).—A description. H. B. MERRILL

Tanning reptile skins. D. WOODROFFE. *Leather Trades Review* **1930**, 840; *J. Intern. Soc. Leather Trades Chem.* **14**, 573. H. B. MERRILL

The theory of chrome tanning in the light of detanning processes. C. STIEPEL. *Kunstdünger u. Leim* **28**, 15–21(1931).—Chrome tanning proceeds in 2 stages, beginning in the alk. bath, but the max. destruction of swelling properties of hide does not result until the bath has become acid from pptn. of a basic Cr compd upon the fibers of the hide. In detanning chrome scrap for glue, 2 products are obtained: one H_2O-sol. and of normal behavior, the other H_2O insol., so-called "chrome glue" obtained by the magnesite process (cf. Stiepel, *C. A.* **25**, 2018), which represents hide substance tanned under acid conditions, more difficult to detan. C. J. SCHOLLENBERGER

Tanno-chemical investigation of chrome salts. GEORG GRASSER AND MASATAKE ICHISE. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. 2, 295–318(1930).—The contraction temp. of the skin, and m. p. of gelatin tanned with different chrome salts, prepd. under different conditions, are tabulated H. B. MERRILL

The gel strength of glue from hide, from chrome leather and from bones and its relation to the viscosity and chromium content. O. GERNGROSS AND H. MENDEL. *Kunstdünger u. Leim* **28**, 109–16(1931).—Ten hide glues, 5 bone glues and 13 glues from chrome leather were investigated. Procedures are described in detail. Gel strength of a 12.5% soln. at various temps. was detd. with the Greiner app. Viscosity of a 17.75% soln. at 40° was measured by the Vogel-Ossag app. The p_H of a 1% soln., water and ash contents of samples are also given, but methods are not described. Cr_2O_3 in chrome glues varied 0.03–4.20%. Among com. Cr glues, there was no connection between Cr_2O_3 and phys. properties, but 3 samples from leather dechromed in the lab. showed progressive improvement in gel strength and viscosity with Cr removal. Chrome glues (with one exception) and bone glues showed higher gel strength than hide glues of the same viscosity. The relation of gel strength to viscosity was fairly regular among all samples and most regular among hide glues. The p_H varied 5.0–7.6, and within this range had no important effect upon viscosity. C. J. SCHOLLENBERGER

Influencing of gelatin-metal salt precipitation by addition of neutral salts. GEORG GRASSER AND HIROSHI OHOKI. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, Pt. 2, 285–8(1930).—The effects of a large no. of Na salts on pptn of gelatin by salts of weak bases and heavy metals are listed. H. B. MERRILL

ERNST GOEBEL. *Kunst-*

compared with ignition over a Bunsen burner. Comparison materials showed that least time and gas were required with Pt, slightly more with "Weta" ware and most with silica and porcelain. With the latter, time and gas consumption were approx. 100% greater than with Pt. C. J. SCHOLLENBERGER

Animal materials for artificial silk, a chemico-technical problem for the glue and gelatin industry. H. MENDEL. *Kunstdünger u. Leim* **28**, 120–1(1931).—If filaments of gelatin could be tanned or fixed while under tension, the tendency of the mols. to orient themselves (cf. Katz and Gerngross, *C. A.* **20**, 528) should result in a fiber with superior strength, which might compete with artificial silk. Investigation of this or similar problems might well be undertaken by the industry. C. J. SCHOLLENBERGER

The collagen fiber. F. HALLA AND R. TANDLER. *Z. physik. Chem.*, Abt. B, **12**, 89–92(1931).—X-ray spectrograms of collagen fibers from *fish skin* were identical with those of gelatin under tension. FRANK URBAN

Changes in the use of adhesives. HERMANN STADLINGER. *Kunstdünger u. Leim* **28**, 8–11(1931).—A general outline is given of the uses of natural adhesives in the past, recent substitution of synthetics and possible new applications for old materials. C. J. SCHOLLENBERGER

Glue and gelatin in the textile industry (STADLINGER) **25.** Refractometric study of chromic acid reduction (GRASSER, OHOKI) **6.** Study of the warble and its eradication (GANSSER) **15.** Uniting rubber and leather (Brit. pat. 338,789) **30.** Substitutes for sugars in [chrome tanning] (Ger. pat. 518,196) **18.**

WIENER, FERDINAND, and WEBER, H.: **Die Lederfärberei und die Fabrikation des Lackleders.** Ein Handbuch für Lederfärber und Lactierer. 4th ed., revised and enlarged. Leipzig: A. Hartleben's Verlag. 220 pp. M. 5; bound, M. 6

Rotary-drum tanning apparatus. E. G. WILSON. Brit. 339,252, Aug. 23, 1929. Structural features.

Removing fat from sheepskins. P. I PAVLOVICH, N. G. SHCHEKOLDIN, V. I. DRELING, K. I. ZYABLOV and V. F. DROZDOV. Russ. appl. 68,138, Apr. 11, 1930. Skived sheepskins are treated with caustic solns. of "Kontakt" (petroleum sulfonic acids) or its soap.

Chrome velvet leather. V. S. AVTONOMOV. Russ. appl. 59,844, Dec. 7, 1929. Chrome leather is treated with warm water followed by an alternating treatment with a soda soln. and Cr alum, and then by the usual treating methods.

Leather for driving belts, etc. A. MCLELLAN. Brit. 338,536, Aug. 19, 1929. Leather for belt conveyors or driving belts is rendered resistant to moisture and wear by buffing and treating with a soln. formed of gutta percha, Sb sulfide or other cold vulcanizing agent, and CS_2 or CCl_4 or both (which may be applied in successive coats, each of which is allowed to dry before applying the next coat). The material may be subsequently subjected to pressure, and may be preliminarily impregnated with rubber. Various details of solns. and procedure are described.

Dyeing leather. N. P. SHAVROV. Russ. appl. 39,491, Jan. 26, 1929. An ext. is obtained by boiling the bark of the larch tree or pine tree with caustic remaining after a complete extn. of tanning material. The leather is dyed with this ext. with the usual metal mordants by the customary dyeing methods.

Dyes for chrome leather. I. G. FARBENIND. A.-G. Brit. 338,930, July 22, 1929. Aromatic *N*-nitroso compds. are warmed with aromatic amino-, hydroxy-, or amino-hydroxy-compds. (suitably in the dye bath at the time of dyeing chrome leather). Numerous examples are given for producing dyeings of various colors.

Monoazo dyes for leather. I. G. FARBENIND. A.-G. Brit. 339,029, Sept. 24, 1929. Dyes giving brown shades on leather are obtained by coupling a diazotized *p*-nitroaniline negatively substituted in *o*-position to the NH_2 group, or a homolog, with a compd. of the diphenylamine series such as diphenylamine or a sulfo or carboxy deriv. Examples are given.

Artificial horn. I. G. FARBENIND. A.-G. (O. Schmidt, K. Seydel and E. Meyer, inventors). Ger. 482,930, Aug. 28, 1926. Casein is worked up by the customary processes after addn. of a small quantity of a liquid or solid hydroaromatic or aliphatic-hydroaromatic base, or an aliphatic base contg. an OH group, or a salt or deriv. of such a base. The use of cyclohexylethanolamine is described in an example.

Glue. PORA-WERK PAUL SCHROT. Ger. 515,868, April 27, 1926. A filling material for animal glue consists of wood dust and such mineral as gypsum or chalk. The filling material is intimately mixed with the glue under pressure.

Glue and gelatin from chrome leather cuttings. BRITISH GLUES & CHEMICALS,

LTD., and R. B. DREW. Brit. 338,584, Aug. 17, 1929. Chrome leather cuttings are subjected to percolation with a soln. of an alk. earth such as magnesia, repeatedly and cyclically in one direction at such a rate that the acid extd. from the leather neutralizes sufficient alkali to maintain the desired alkalinity (a p_H of 8–8.5 being suitable). A temp. of 105° is suitable for thick cuttings and undesirable sol. matter such as salt may be removed by a preliminary extn. at room temp. Various details of app. and procedure are described.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The chemical technology of rubber. SIDNEY M. HAGMAN. *Reprint from Svenska Gummi Ind. Memorial Number*, issued on the occasion of Disponent Henry Dunkers' 60th anniversary, September 6, 1930.—A general discussion. H. C. DUUS

A modern service laboratory—the I. C. C.'s work for the rubber industry. ANON. *Chem. Trade J.* **52**, 100–1(1931). - A description is given of the new service lab. for the rubber industry that has been equipped by the Brit. Dyestuffs Corp., Ltd., at Hexagon House, Blackley, near Manchester. One section deals with the solution of technical problems, the second with the routine testing of rubber industry chemicals and colors and the third with research. W. H. BOYNTON

The world's rubber supplies. GEO. RAE. *Bull. Rubber Growers' Assoc.* **13**, 59–84 (1921).—Though chiefly economic, the paper is of general interest, as it deals with planted areas, output, exports, imports, consumption and stocks in the producing and mfg. localities. C. C. DAVIS

Metallurgical methods used in producing rubber. PAUL D. V. MANNING. *Chem Met. Eng.* **38**, 131–2(1931).—An illustrated description is given of new machinery for planting, cultivating and prepg. guayule. C. C. DAVIS

Patents and custom standards of new machines for the manufacture of rubber articles. RUDOLF DITMAR. *Kolloid-Z.* **54**, 237–9(1931).—A review. A. FLEISCHER

The use of pigments in the rubber industry. FERD. A. RICHTER. *Farbe. u. Lack* **1931**, 135.—The primary use of pigments in rubber is not for the color but for the phys. properties imparted to the rubber. The choice of pigment depends upon the method of vulcanization as well as the use to which the product is put. G. G. SWARD

Reënforcing action of pigment mixtures on rubber compounds. D. J. BEAVER AND J. W. MACKAY. *Ind. Eng. Chem.* **23**, 294–6(1931).—The exptl. data which are presented show that mixts. of varying proportions of either channel gas black or a "soft" C black with whiting, lithopone or clay impart additive phys. properties to the vulcanizate. Mixts. of "soft" C black with ZnO also impart additive properties, whereas mixts. of channel black with ZnO result in poorer resistance to abrasion, in a higher modulus and in a higher tensile strength than those corresponding to the additive effects. These facts are explained by a chem. reaction between the basic ZnO and the acidic compds. in the rubber or on the C black. These results are applied to the formulation of a solid tire rubber mixt., which shows a greater resistance to abrasion and to "blow-out" when it contains a "soft" black than with a channel gas black. C. C. D.

American-grown rubber produced from guayule. GEO. H. CARNAHAN. *Chem. Met. Eng.* **38**, 128–31(1931).—An illustrated description of recent developments (cf. Spence, *C. A.* **24**, 2914). C. C. DAVIS

Physical tests of sponge rubber. F. L. HAUSHALTER. *India Rubber World* **83**, No. 5, 59–60(1931).—An *app.* to measure the compressibility and the permanent set after compression of sponge rubber is described and illustrated. C. C. DAVIS

Soft rubber in chemical process equipment. H. E. FRITZ. *Chem. Markets* **28**, 273, 275, 277(1931).—An illustrated description is given of the application of rubber to ball mill linings, and machinery bearings, with special reference to the Vulcalock process. C. C. DAVIS

Chemical constitution of rubber. MARIO D. PINTO. *Rev. brasil. chim.* **2**, 267–70 (1930).—P. discusses the work of the early investigators, and shows the evolution of the present formula $(C_5H_8)_x$. JOHN M. LADINO

Isoprene and rubber. XXII. Isorubber-nitrone. H. STAUDINGER AND H. JOSEPH. *Ber.* **63B**, 2888–99(1930); cf. *C. A.* **24**, 4954.—Pummerer's view that the unit mol. of rubber is $(C_5H_8)_3$ is supported by mol.-wt. detns. on rubber in menthol and especially on isorubber-nitrone (I) in C_6H_6 and $PhNO_2$. These results, which have been confirmed as to their order of magnitude, are apparently not in agreement with Staudinger's view, based on model expts. with polystyrenes, the conversion of rubber into col-

loid-sol. rubber-phosphonium salts, the prepn. of polymer-homologous series of polyprenes, the degradation of rubber, the relationship between viscosity and mol. wt., etc., all of which lead to the conclusion that the primary colloid particles of rubber, *i. e.*, the particles in dil. soln., are macromols. contg. some 1000 isoprene mols. joined in a chain (mol. wt. around 68,000). A study of the action of PhNO on rubber solns. gave results somewhat different from those of Pummerer and Gündel. They believed that the resulting decrease in viscosity is due to the disturbance of the rubber micelles. It has been found, however, that the viscosity of solns. of macromol. (eucolloid) polystyrene is greatly diminished by Cl, Br, strong oxidizing agents (N oxides, O_3), etc., as the result of an irreversible cleavage of the long sensitive macromols. into shorter fragments having a hemi-colloid character. The viscosity changes (often considerable) produced in highly viscous rubber solns. by the addn. of reagents are also irreversible, and therefore cannot be due to adsorption of the reagent on the colloid particles or to changes in their micellar structure. The macromols. of rubber, because of their double bonds, are much more sensitive than the satd. macromols. of polystyrene, and their cleavage into shorter fragments of hemi-colloidal character is a primary phase of almost all transformations undergone by rubber. To det. the extent of such a cleavage in the reaction with PhNO, varying quantities (0.01–3.0 mols.) of PhNO were added to a 0.2 *M* soln. of rubber (purified according to Pummerer) in C_6H_6, and after 24 hrs. at 20° the time of flow from an Ostwald viscometer was noted. Parallel expts. were made with NO_2 and Bz_2O_2. Below are, resp., the no. of mols. of reagent used and the viscosity of the resulting soln. as compared with pure C_6H_6 taken as 1: PhNO 0.01, 3.2; 3.0, 1.4. NO_2 0.01, 2.1; 0.05, 1.9; 0.1–1, product pptd. out. Bz_2O_2 0.01, 3.6, 0.5, 2.9. $PhNO_2$ 0.1, 3.7; 1, 3.7. Rubber soln. alone 3.6. If I, then, is not a deriv. of rubber itself but of oxidative degradation products, it should contain somewhat more O than that calcd. for pure isorubber-nitrone, and such is the case. In P. and G.'s published analyses only 2 show C values equal to the theoretical, the other 5 being 1–1.5% too low. S. and J. in about 20 analyses obtained values 1.5–2% too low although they completely excluded air in the prepn. of the I and carried out the filtration and washing in a N atm. As to the mol. wt. of the product, a series of detns. in 1% C_6H_6 soln. gave values about twice as large as in $PhNO_2$, but the latter, which on the av. were only slightly higher than P. and G.'s, varied considerably. I is not a homogeneous substance but a mixt. of polymer-homologous products which can be sepd. by means of cold C_6H_6 into more easily and less easily sol. portions of approx. the same compn. but with different mol. wts. in $PhNO_2$, and forming $CHCl_3$ solns. of different viscosities. Furthermore, it was shown by isothermal distn. in Signer's app. (*C. A.* 24, 4433) that in equally concd. solns. of the 2 portions there are fewer mols. in the soln of the less sol. portion. The reaction with PhNO does not permit of detg. whether the mol. of rubber is made up of 100 or 1000 isoprene residues. **XXIII. Cryoscopic measurements on rubber solutions.** H. Staudinger and H. F. Bondy. *Ibid* 2900–5.—Reply to Pummerer, Andriessen and Gündel (*C. A.* 24, 1102). Mol.-wt. detns. on rubber in camphor cannot serve to clear up the structure of rubber, for, as already shown, the rubber undergoes extensive degradation to hemi-colloidal cleavage products when heated in molten camphor (170–80°). The ratio of the time of flow of a C_6H_6 soln. of rubber which has been dissolved in molten camphor to the time of flow of a soln. prepd. from the same quantities of rubber and camphor without heating is about 1:15; the rubber recovered from the former soln. has the properties of a deeply degraded hemi-colloidal rubber, is smeary, has almost completely lost its viscosity, dissolves without swelling and forms solns. of low viscosity. The relative viscosities of a 0.2 *M* soln. of pure rubber in tetralin are 14.89 and 2.60, resp., before and after the rubber has been heated with camphor. The sepn. of mixed phases observed by P. and Andriessen in attempts to det. the mol. wt. of rubber in freezing C_6H_6 is easily explained by the fact that concd rubber solns. in C_6H_6 (1%) are not sol but gel solns.; for rubber purified according to P. the limiting concn., *i. e.*, the transition from sol to gel soln., is about 0.5%, and it is only in the dil. sol solns. that mol.-wt. detns. can be made successfully. With the hemi-colloidal degradation products, mol.-wt. detns. can be made by the f.-p. method, the limiting concn. of a degraded rubber of polymerization degree 100 is reached in an approx. 5% soln. P. and Gündel express the opinion that S.'s rubber was not completely N-free, but G. and B. were unable to detect any N by heating with K, although a control showed that 0.01% N can be detected in this way. C. A. R.

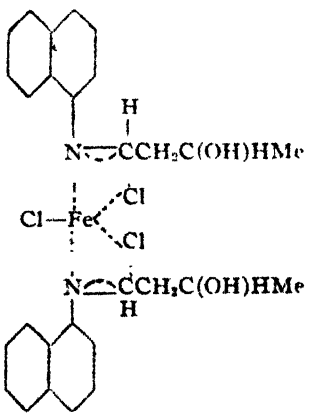
Swelling pressure of rubber. Paul Stamberger. *Nature* **127**, 274(1931); cf. *C. A.* 24, 4659.—The formula $P = K/V^3$ gives satisfactory results with the data of the previous paper, where P is the swelling pressure, V is the vol. of solvent bound to a unit wt. of jelly, and K is a const. whose meaning is expressed by substituting the above

equation in the max. work term: $dA = PdV$. The swelling pressure results from the attraction of solvent mols. by the mols. of the gel. ARTHUR FLEISCHER

The action of lead selenide in rubber mixtures. R. DITMAR AND K. H. PREUSSE. *Caoutchouc & gutta-percha* 28, 15448–50(1931).—Recent interest in Se in the rubber industry led to a study of its derivs. as possible valuable compounding ingredients. The present paper continues the previous work on Se red (cf. *C. A.* 24, 4663; D. and Preusse, *C. A.* 24, 4659). Zn selenosulfide (5% Se) and K_2SeSO_3 had no notable effect in rubber mixts., either on the rate of vulcanization or otherwise, so PbSe was next examd. A finely-ground natural product (hardness 2.5–3, d. 8.2–8.8) was used. In rubber-S mixts., PbSe has no influence on the rate of vulcanization nor any reënforcing effect. On the mixing mill, PbSe has a strong plasticizing action which becomes marked with 4% PbSe, and accordingly this property may be utilized in prepg. adhesive cements from rubber. In the mixt.: crepe 100, S 3, PbSe 2, accelerator 2, whiting 30, the PbSe acts as a very powerful activator with the majority of com. accelerators (the results with 16 are tabulated), so that no other activator is needed, and it also reënforces the vulcanizates, particularly in increasing their resistance to abrasion. Its action, therefore, resembles that of Se. On increasing the PbSe in an accelerated mixt. to 100 parts on the rubber, the reënforcement increased continuously. In cures with S_2Cl_2 in CS_2 or with S_2Cl_2 vapor, PbSe had no action at all, except that because of its softening action (*loc. cit.*) the cure had to be prolonged. C. C. DAVIS

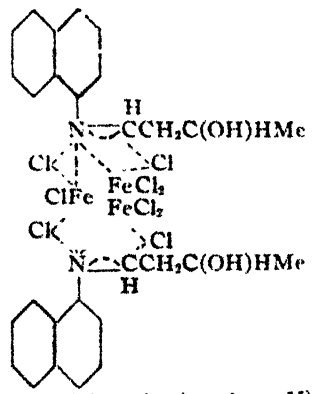
Liquid rubber and carpets. WEBSTER NORRIS. *India Rubber World* 83, No. 6, 56(1931).—An illustrated description is given of the application of rubber dispersions in a new type of carpet. C. C. DAVIS

The curing of sheet rubber. T. E. H. O'BRIEN. *Trop. Agr.* (Ceylon) 75, 280–92 (1930).—Smoking of sheet rubber prevents undesirable surface stickiness. Unsmoked sheet contg. *p*-nitrophenol is inferior in aging properties to a like sample without *p*-nitrophenol. Smoked sheet after vulcanization is superior in aging properties to unsmoked sheet when both contain *p*-nitrophenol. A sheet weighing 1.5 lb. and measuring 23 × 18 in. is of correct thickness for efficient drying, combined with good appearance, and is also the most suitable size for packing in a standard rubber chest. J. O. H.



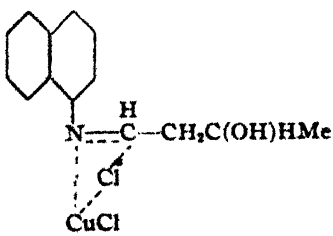
The consistency of the particles in balata latex. E. A. HAUSER. *Kautschuk* 7, 2–3(1931); *Gummi-Ztg.* 45, 1030(1931).—The expts. deal with balata latex from Peru, which was preserved with AcOH. For this reason the acid character of the latex may have brought about certain changes in the consistency of the particles, so that the conclusions drawn from the expts. do not necessarily hold good for the particles of fresh latex. The micromanipulator examn. was carried out with the aid of a new kind of dark-field condenser, with the finest microneedle which was equipped with a new device for its control (cf. *C. A.* 25, 1409). The examn. shows that there are 2 kinds of particles in such latex: (1) a uniformly tacky kind, which probably represents the resinous components of the latex, and (2) a smaller kind of particle which does not have a homogeneous structure. This 2nd type consists of a viscous inner part and a plastic outer part, which even has a certain degree of elasticity. By evapn. of the latex or by addn. of coagulating agents the consistency of the 1st type changes only slightly or not at all, whereas the 2nd kind of particle contracts to a homogeneous mass. The 2nd kind of particle probably therefore represents the actual balata hydrocarbon. Further expts. proved that during the evapn. only the particles of the 1st type fuse together, whereas the particles of the 2nd type remain distinctly sepd. from each other. This latter fact probably depends upon each hydrocarbon particle having an adsorbed skin of the non-balata components dissolved in the serum. This observation is of particular interest, since it offers the possibility of obtaining pure balata by some convenient method, such as fractional pptn. or fractional sepn. from the latex, without having to resort to extn. C. C. DAVIS

Gathering, treatment and properties of guttapercha. H. R. BRAAK. *Chem. Weekblad* 27, 567–71(1930).—A review. A. L. HENNE

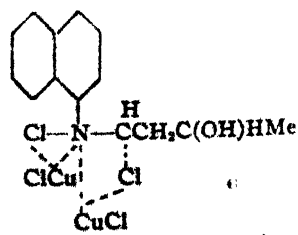


Age-resistant rubber. A survey of United States and foreign patents for chemical prevention of the deterioration of rubber. JOSEPH ROSSMAN. *India Rubber World* 83, No. 5, 65–8(1931). C. C. DAVIS

The protective action of some antioxidants. II. The metal halide compounds of some protective agents against aging, with special reference to aldol-α-naphthylamine. F. KIRCHHOF. *Kautschuk* 7, 7–12(1931); cf. *C. A.* 23, 3371.—It has already been shown that alc. solns. of heavy metal chlorides change the color of alc. solns. of certain antioxidants like aldol-α-naphthylamine (I), "Stabilite Alba" (II) and "Agerite powder" (III), both when viewed in visible and in ultra-violet light. The present paper, in which the behavior of I in particular was studied, attempts to explain this



phenomenon, which is of importance not only from the antioxidant point of view, but because of the discoloration of vulcanizates contg. such antioxidants. With $AuCl_3$, $CuCl_2$, $FeCl_3$ and $PtCl_4$, I gives cherry-red colors at low concns. and intense blue colors at higher concns. of the metal chlorides. The blue colors are, however, unstable and change to violet, then to cherry-red. With $AlCl_3$, $AsCl_3$, $CoCl_2$, $FeCl_2$, $HgCl_2$, $MnCl_2$, $NiCl_2$, $SbCl_3$, $SnCl_2$, $SnCl_4$, $TiCl_3$, UO_2Cl_2 and $ZnCl_2$ no colors are obtained. While $AuCl_3$, $CuCl_2$, $FeCl_3$ and $PtCl_4$ cause the disappearance of the fluorescence of I in ultra-violet light, $SbCl_3$ is the only other chloride of those above which affects the fluorescence, and this gives a yellow-white ppt. From the cherry-red I solns. with $CuCl_2$ and $FeCl_3$, chocolate and coffee-brown *ppts.* with high Cu and Fe contents sep. on long standing, and these remain dark even after long washing with EtOH. Their C_6H_6 solns. are intense yellow-brown. Analysis of the ppts. showed that the Cu ppts., which vary from coffee-brown to ocher-yellow, are adsorption compds. of the cherry-red sol. Cu-I compds. with solid I, and that the Fe ppts., which are chocolate-brown, are adsorption compds. of the sol. cherry-red Fe-I compds. with solid I. These reactions are not the same as that of aq. I with aq. $FeCl_3$, $ZnCl_2$, $AgNO_3$ and CrO_3 (cf. "Meyer-Jacobson," II, 350), because water and dil. alkalies cause cleavage of the alc. Cu and Fe compds., with formation of blue-violet flocculant ppts. which contain no metal and which become yellow-brown in air. Since these color reactions are confined to chlorides of a higher state of oxidation, the more loosely combined halogen plays the essential part. The fact that the reaction with $CuCl_2$ is in every case more rapid than with $FeCl_3$ may be utilized to distinguish analytically small quantities of these compds. A similar color reaction occurs with free halogen, *e. g.*, Br in CCl_4, where a deep indigo appears immediately, changes to violet, then to cherry-red and finally to yellow-brown. These Br addn. compds. give no color reaction with $FeCl_3$ or $CuCl_2$, so that in the color reaction the metal halide combines at the double bond between the N and CH. Since the cherry red I-$FeCl_3$ and I-$CuCl_2$ compds. are decompd. by small quantities of HCl to yellow-brown products, only unstable compds. are formed, and since the quantity of addn. compd. depends upon the concn. of halide, the N does not always have the same valence, and the following formulas are assigned:



Cherry-red soln. (3-valence N) from low $FeCl_3$ concn. Stable

Blue-violet soln. (4-valence N) from high $FeCl_3$ soln. Unstable

Cherry-red soln. (3-valence N) Stable

Blue soln. (4-valence N) Unstable

These resemble the hemin (IV) formula of Willstätter and Küster. The I-metal halide solns. absorb all visible light up to a bright band in the red and orange between 560 and 680$\mu\mu$, and since HCl-solns. of IV show a similar band, the absorption limits may be characteristic of the $FeCl_3$ and $CuCl_2$ groups. The ultra-violet fluorescence of all the I-metal halide compds. is very feeble compared with that of the original substance, and the colors vary greatly. The following fluorescent colors appeared in EtOH in ultra-violet light: I, intense sky-blue; I + $FeCl_3$, very pale violet; I + $CuCl_2$, pale yellow-green; I + $CuCl_2$ + HCl, pale green-brown; I + Br, pale violet; II intense violet; II + $CuCl_2$, pale yellow-green; II + $CuCl_2$, pale yellow-green; II + $CuCl_2$ + HCl, pale green-brown; II + Br, pale brown; IV + alc. HCl, pale red-brown. The source of the strong fluorescence is probably in the N:CH double bond, and it is lost by addn. of the halide. The O-transporting power of Fe in hemin occurs also in the I-metal halide and II-metal halide compds., for I soln. made pale rose by $FeCl_3$ becomes deep blood-red when O is passed through it, whereas I soln. alone is pale yellow. The O-transporting power of the $CuCl_2$ compds. is many times greater than that of the corresponding Fe compds. and this agrees with the similar behavior of Fe and Cu compds. in rubber. With 1% $CuCl_2$, O caused a turbidity with I and intense carmine with II, by the formation of oxidation products, and after prolonged passage of O, about 50% of the dissolved substances sepd. as a chocolate-brown *ppt.* contg. only a small percentage of combined Cu. Treatment of I soln. contg. $FeCl_3$ for many hrs. gave an intense carmine color, with no insol. oxidation products. Not only is the autoxidation of antioxidants greatly accelerated by their $FeCl_3$ complexes and especially by their $CuCl_2$ complexes, but it is inhibited by catalytic poisons. Thus with II-$CuCl_2$ soln., a little HCN greatly retards the time of appearance and the intensity of the carmine which is formed upon treatment with O. III gives no immediate color with alc. $FeCl_3$ or $CuCl_2$, but on long standing in air a brown color appeared, because of oxidation. III is probably more stable than I and II toward oxidizing agents and oxidation catalysts. In titrating III in ultra-violet light, the quantity of $FeCl_3$ required to destroy the violet fluorescence is approx. 2 mols. of $FeCl_3$ per mol. of III. II gives no immediate color with $FeCl_3$, but on long standing a carmine color appears, especially in light. II and $CuCl_2$ give an immediate yellow or yellow-brown which changes soon to deep carmine. The carmine solns. with II and $FeCl_3$ and $CuCl_2$ show similar spectral properties, and are not changed by HCl, in contrast to the colors with I complexes. In titrating in ultra-violet light, only 0.5 mol. of $FeCl_3$ or $CuCl_2$ is required to destroy the fluorescence of the II-$FeCl_3$ and II-$CuCl_2$ complexes. Based on the similar absorption spectra of these metal halide complexes with the previous ones, they probably contain similar $FeCl_3$ and $CuCl_2$ complexes which cause the colors. The Fe complex

would be $PhN.CH_2.CH_2.NPh.FeCl$, where the stability toward HCl results from the formation of high valences. Since antioxidants are oxidized in time by autoxidation they protect an antioxidizable substance like rubber only as long as they remain active. Since traces of sol. heavy metal compds., especially of Fe, are invariably present in rubber compounding ingredients, rubber mixts. which contain protective agents are discolored by the formation of dark colored metal complexes and their oxidation products.

New light on vulcanization. The process as revealed by electrical tests. W. H. Nuttall and J. Kirkwood. *India Rubber J.* **80**, 657-60(1930).—A review and discussion, with particular reference to the work of Curtis, McPherson and Scott (*C. A.* **22**, 330), Kitchen (*C. A.* **23**, 2375) and Boggs and Blake (*C. A.* **24**, 4425). C. C. D.

Tensile tests of vulcanized rubber at high speed. A. van Rossem and H. B. Belverdam. *Rev. gén. caoutchouc* **7**, No. 57, 27-34(1930).—Most of the testing machines used for detg. the elongation of rubber have a slow speed, and 60 cm. per min. is somewhere near the speed usual in practice, regardless of the state of cure. This is in spite of the fact that undervulcanized rubber, which has a high elongation when stretched at slow speed, is brittle when stretched very rapidly, and has an extremely low elongation. For this reason, it was of interest to make elongation tests at high speeds. No app. was available for recording the stress-strain curve, and resort was had to the pendulum app. of Charpy. The technic employed in adapting this app. to the present expts. is described and illustrated. Different accelerated rubber mixts. at various states of cure were tested in this way. The energy at rupture was calcd. and the results were compared with tests on the Schopper dynamometer. The results show that (1) the max. energy at rupture as a function of the time of vulcanization is much more sharply defined at the high speeds of the pendulum app. than in the tests with the Schopper machine, and (2) the max. strength with the pendulum app. is at a

lower state of cure than with the Schopper machine. With vulcanizates contg. a low percentage of S, *e. g.*, the mixt.: rubber 100, S 3, diphenylguanidine 1, ZnO 5, the pendulum app. gives a less sharply defined max., but nevertheless here too this max. is at a lower state of cure than that with the Schopper machine. The influence of loading with pigments and fillers was also studied. The magnitude of the max. depends upon the substance added, but the sharpness of this max. and its relation to the time of vulcanization are independent of the nature of the filler. Accelerated aging tests were made in the Geer oven at 70° and the aged vulcanizates were then tested in the same way. After aging, the time of cure/energy at rupture curve obtained from the Schopper machine was similar to that obtained from the pendulum app. before heating. The energy at rupture curve detd. by the pendulum app. is therefore of great importance in relation to the state of cure, because the time of vulcanization which corresponds to the max. energy at rupture by the pendulum app. is, contrary to the time of vulcanization corresponding to the max. tensile strength by the Schopper dynamometer, the time of vulcanization which corresponds to the best aging. The importance of tests at the high speeds and the shortcomings of the pendulum app. for this purpose make it desirable that an app. be developed which at a very rapid speed of stretching will: (1) det. the resistance to stress, the ultimate elongation and the energy at rupture; (2) record graphically the relation between the stress and the elongation and (3) perform at different speeds. Also in *Kautschuk* **6**, 224–9(1930). C. C. Davis

Hard spots in vulcanized rubber compounds. J. H. Howby. *Ind. Eng. Chem.* **23**, 287–90(1931).—Expts. are described, the object of which was to ascertain the cause of local variations in the hardness of exptl. slabs of rubber mixts. of the C black tread type. It was found that areas of excessive hardness correspond to regions where the max. flow or displacement occurs when the rubber mixt. is pressed into the mold at the time of curing. A knowledge of this fact is of importance in testing the hardness of a vulcanizate by the Am. Soc. of Testing Materials standard of hardness, and for increasing the precision and reliability of this convenient test. It was also found by chem. analysis that these variations in hardness cannot be attributed to heterogeneous regions (non-uniform compn.) in the rubber-S-accelerator-pigment mixt., and it is concluded that the variations must depend either upon altered conditions of dispersion in the regions of max. displacement or else upon a local grain effect set up by the flow. C. C. Davis

Use of vulcanized rubber waste as a fixing agent in bronze printing. Geo. Rice. *Rubber Age* (N. Y.) **28**, 611–2(1931).—An illustrated description. C. C. Davis

Monoxanthogens [vulcanization accelerators] (U. S. pat. 1,796,972) **10**. Substitutes for sugars in coagulating latex. (Ger. pat. 518,196) **18**. Dispersion of carbon black in water (Can. pat. 309,276) **18**.

Purifying latex. K. D. P., Ltd. Brit. 338,766, Dec. 20, 1928. Latex is subjected to heat treatment with simultaneous evapn. and then subjected to a usual purifying treatment, as by centrifuging to sep. serum, which is facilitated by the pretreatment.

Device for spraying rubber latex by an air jet. Charles E. Maynard (to Fisk Rubber Co.). U. S. 1,795,875, March 10. Structural features.

Rubber. K. D. P., Ltd. (Rudolf Pummerer and Hans Kroepelin, inventors) Ger. 515,603, May 26, 1926. Addn. to 460,950. Pure rubber hydrocarbons are prepd. from rubber latex by treating with alkali in an electrodialyzer.

Rubber compositions. Dunlop Rubber Co., Ltd., E. A. Murphy, A. Niven and D. F. Twiss. Brit. 338,975, Aug. 30, 1929. Crumb-like rubber compns. are prepd. by coagulating an aq. dispersion of rubber or the like, by pptn. *in situ* (in relatively large amounts on the dry rubber content) of compounding ingredients formed by the interaction of one or more water-sol. reagents normally having no coagulating effect, with other added water-sol. reagents, such as reagents which together form products such as $MgCO_3$, $CaCO_3$, $ZnCO_3$, Ca, Ba or Zn silicates, silicic acid or Zn, Cd or Pb sulfides. Soap, glue, gum acacia, etc., may be added to modify the properties of the product.

Use of amines as rubber coagulants. Albert J. Gracia (to Goodyear Tire & Rubber Co.). U. S. 1,797,192, March 17. Latex is coagulated by use of amines such as ethylamine, diethylamine, propylamine, dipropylamine, tripropylamine, butyl amine, amylamine, iso-amylamine, di-isoamylamine or allyl amine.

Preserving rubber. Lorin B. Sebrell (to Goodyear Tire & Rubber Co.). U. S.

1,797,179, March 17. Anilinohexylideneaniline (suitably in the proportion of about 0.5%) is added to rubber compns. before vulcanization.

Rubber "antioxidant." Wm. S. Calcott and Wm. A. Douglass (to E. I. du Pont de Nemours & Co.). U. S. 1,796,980, March 17. Deterioration of rubber is retarded by the addn. of a small proportion (suitably about 0.5–2.5%) of a transparent brittle solid obtained by the reaction of glucose on *m*-tolylenediamine.

Trinaphthylamine. Albert M. Clifford (to Goodyear Tire & Rubber Co.). U. S. 1,797,196, March 17. This compd. is obtained by extn. with C_6H_6 from crude dinaphthylamines and is an antioxidant for rubber.

"Micro-porous" rubber. H. Beckmann. Brit. 338,698, Oct. 26, 1928. The process described in Brit. 240,430 (*C. A.* 20, 2262) is modified by adding to the latex a substance capable of being coagulated to form a hydrophilic gel, such as 2% of blood albumin, and then adding a coagulating agent, such as HOAc, which will cause coagulation of both the latex and the added substance. Among the substances which may be added are: silicic acid, stannic acid, $Al(OH)_3$, colloidal Fe_2O_3, colloidal chromic oxide, colloidal tungstic and molybdic acids, manganic hydroxide, V pentoxide, albuminoids, polypeptides and hemoglobin, and substances such as silicic acid may be formed in the latex by reaction. Cf. *C. A.* 24, 752.

Apparatus for molding rubber articles such as tennis balls. Harry Willshaw and Sydney N. Goodhall (to Dunlop Tire & Rubber Corp.). U. S 1,795,917, March 10. Various structural features are described.

Uniting rubber and leather. K. Ehmke. Brit. 338,789, Jan. 8, 1930. Materials such as shoe parts of rubber are roughened on a grinding wheel, coated with rubber soln., sprayed with particles of crepe rubber and further coated with rubber soln. and then united by hammering with leather coated with rubber soln.

Attaching rubber to metals. C. M. Carson (to Goodyear Tire & Rubber Co.). Brit. 339,421, Feb. 23, 1929. A cement is used consisting of latex, hemoglobin, a tanning agent such as formaldehyde, $K_2Cr_2O_7$, $K_4FeC_6N_6$ or $Al_2(SO_4)_3$, and vulcanizing ingredients and this cement is vulcanized after application.

Compositions containing rubber and cement. N. Swindin and Nordac, Ltd. Brit. 339,002, Sept. 5, 1929. In making a material suitable for floors, road surfaces or acid-resisting coating, raw rubber (heated or swelled with a solvent) is dispersed with water (preferably in the presence of a hard porous inert powder such as fine coke dust which acts as a triturating agent), suitably with addn. of emulsifying agents such as soap, saponin, borax, NH_3 and soda, and the material is then mixed with a cement (such as portland or oxychloride cement materials) which reacts with the water and causes setting of the mass. Various details and use of different fillers, etc., are described.

Films, threads, disks, etc. I. G. Farbenind. A.-G. Fr. 37,485, Oct. 3, 1929 (Addn. to 676,658 (*C. A.* 24, 3135). Mixts. of natural rubber with the polymerization products of butadiene hydrocarbons are treated with sulfuring agents until the high plasticity characteristic of rubber disappears.

Isomerizing rubber. Imperial Chemical Industries, Ltd., and E. B. Robinson. Brit. 339,398, Sept. 30, 1929. Rubber is liquefied by heat and then treated with isomerizing substances such as H_2SO_4, sulfonic acids, sulfonyl chlorides, sulfuric esters or metallic halides, with or without phenolic compds., to produce a thermoplastic product. Various details of procedure are given.

Apparatus for curing tire flaps. Robert W. Snyder (to Goodyear Tire & Rubber Co.). U. S. 1,797,180, March 17. Structural features.

Rubber conversion product. Herman A. Bruson (to Goodyear Tire & Rubber Co.). U. S. 1,797,188, March 17. See Can. 299,963 (*C. A.* 24, 3135).

Synthetic rubber. I. G. Farbenind. A.-G. Brit 338,534, Aug. 17, 1929. Polymerization of diolefins such as butadiene is effected in the presence of alkali or alk. earth metals or their alloys in particles of uniform size, such as with Na balls of 1.1 mm. diam. in a rotating Fe autoclave at 40°.

Synthetic rubber. I. G. Farbenind. A.-G. Brit. 339,135, Dec. 20, 1929. Polymerization of diolefins such as butadiene with an alkali metal such as Na is effected in the presence of at least 25% of a low b.-p. aliphatic ether such as dimethyl, diethyl or methylethyl ether (these ethers serving both as diluents and as catalysts). Various details and examples are given.

Synthetic rubber. I. G. Farbenind. A.-G. Brit. 339,243, Aug. 30, 1929. Polymerization of diolefins such as butadiene is effected in the presence of alkali or alk. earth metals or their alloys such as Na amalgam or of alkali or alk. earth metal compds. with org. radicals which are not capable of ionization (such as Na ethyl, K ethyl, K diphenylmethylmethane, Na triphenyl methane and Li alkyls) and the polymer-

ization agent is added gradually or in at least 3 successive portions during the polymerization. The polymerizing agent may be mixed with other substances such as polymers of diolefins, rubber, paraffin, salt or waxes. Several examples are given.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 339,255, Aug. 30, 1929. Rubber-like products suitable for various purposes similar to those for which rubber is usually employed are obtained by polymerizing a mixt. of a diolefin such as erythrene, isoprene, butadiene, methyl- or dimethyl-butadiene, with styrene (suitably after emulsification of the initial materials together with Na stearate or other suitable emulsifying agent). The polymerization may be carried out at 40-60° for several days, and products of different properties may be produced by varying the proportions of the starting materials.

Synthetic rubber. I. G. FARBENIND. A.-G. Fr. 37,374, Aug. 29, 1929. Addn. to 655,217 (*C. A.* **23**, 4103). Synthetic rubber, etc., is intimately mixed with finely divided soot such as lampblack or C black before vulcanization.

Thiuram disulfides. GEORGE C. BAILEY (to Roessler & Hasslacher Chemical Co.). U. S. 1,796,977, March 17. Compds. suitable for use as rubber vulcanization accelerators and having the general formula R_1-CS-S-S-CS-R_1 are made by treating a compd of the type R_1-CS-S-M with NaOCl, R_1 comprising an org. radical and M a metal radical. Tetramethylthiuram disulfide is made by treating Na dimethyldithiocarbamate with NaOCl in aq. soln.

Rubber vulcanization accelerators. RUBBER SERVICE LABORATORIES, INC. Brit. 339,352, Sept. 7, 1929. Accelerators are prepd. by reaction of an aldehyde amine such as butylidene isoamylamine with a substituted unsatd. aldehyde such as α-ethyl-β-propylacrolein. Various details of procedure for manuf. and use of the accelerator are described. Cf. *C. A.* **24**, 266,752.

Apparatus for vulcanizing automobile tires. MATTHEW [illegible] testing [illegible]. U. S. 1,795,680, March 10. Structural features.

Vulcanizing rubber. INDUSTRIAL PROCESS CORP. Brit. [illegible] Nov. [illegible] heterogenes. See Fr. 681,061 (*C. A.* **24**, 4426). U. S. 1, [illegible] it is co[illegible]ine or

Vulcanizing rubber. HAROLD GRAY (to B. F. Goodrich Co.). U. S. 1,796,240, March 10. A product formed by reaction of an org. amine such as aniline or [illegible] and an aliphatic aldehyde such as butyric aldehyde 3 or more mol. proportions is used as an accelerator.

Rubber vulcanization. ADRIEN CAMBRON (to Roessler & Hasslacher Chemical Co.). U. S. 1,796,240, March 10. An accelerator is used comprising the product obtained by causing aniline and acetaldehyde, under essentially anhyd. conditions, to react in the presence of a small quantity of $ZnCl_2$. Cf. *C. A.* **24**, 2640.

Vulcanized colored rubber. RUDOLPH KEECH (to I. G. Farbenind. A.-G.). U. S. 1,796,656, March 17. Before vulcanization, there is incorporated with rubber an insol. metal salt such as the Ba salt of an acid anthraquinone dye contg. at least one amino group, such as 1-amino-4-phenylaminoanthraquinone-2-sulfonic acid, and the material is then vulcanized.
